The measures were analysed to identify them as NWRM or not and, if so, to code them according to the EU NWRM initiative[5]. The survey enhances measures activated in the Italian territory, which can provide several benefits of NWRM. This is relevant in the context of the mapping of ecosystem services required by the EU Biodiversity (COM(2020) 380) and Green Infrastructure (COM/2013/0249 final).

As described by the International Union for Conservation of Nature, NbS are nature-based solutions for the protection, sustainable management and restoration of natural and modified ecosystems that effectively and adaptively address societal challenges while providing benefits for human well-being and biodiversity. To clarify the implications of this work for the session on Nature-Based Solutions for Sustainable Soil and Water Management, it is appropriate to specify which aspects of NBS this work aims to support. As highlighted in the latest technical report published by the Joint Research Centre, the European Commission's science and knowledge service (Drought in Europe, June 2023), European countries are facing a severe drought. The significant lack of rainfall is also affecting northern Europe, making these areas increasingly vulnerable to water scarcity. A major concern in achieving sustainable food production is the impact of water scarcity on crops and vegetation. Researchers and educational institutions are working on a global and national scale to provide more interesting results related to agricultural systems modelling. In this context, AquaCrop is a useful tool for the protection and management of water resources in the field. Among these crop growth simulation models, Aquacrop focuses on water productivity and can be used to plan irrigation strategies, optimize consumption, increase farmers' profitability in situations of water scarcity. The aim of this study is to identify the aspects and functionalities of AquaCrop that need to be improved, considering users' preferences, in order to ensure successful implementation and achieve a more sustainable use of water resources. The results of questionnaires were analysed using the Analytic Hierarchy Process (AHP). The study encourages the development of the ranking of a specific set of characteristics to adapt AquaCrop use to users' needs. The improving scenario of AquaCrop tool must consider the most relevant criterion according to users C3- data is an important function because the system can be configured to communicate automatically with an external IoT platform.

##### NATURE-BASED SOLUTIONS FOR FLOOD MITIGATION AND SOIL CONSERVATION IN MEDITERRANEAN MOUNTAIN AREAS

E. NADAL-ROMERO<sup>1</sup>, M. CORTIJOS-LÓPEZ<sup>1</sup>, M. LLENA<sup>1</sup>, N. LANA-RENAULT<sup>2</sup>, J. ZABALZA<sup>1</sup>, P. SANCHEZ-NAVARRETE<sup>1</sup>, T. LASANTA<sup>1</sup>

<sup>2</sup> University of La Rioja, Logroño, SPAIN

During the 20th century, farmland abandonment emerged as the predominant landscape change in Mediterranean mountains, leading to the expansion of shrubs and forests. The global consequences of this process have been widely discussed in the literature, with positive and negative effects, including landscape homogenization, increasing forest fire risk and decreasing streamflows. Post-abandonment management policies in Mediterranean mountains have encouraged the adoption of Nature-Based Solutions (NBS), being the most used natural revegetation, afforestation and shrub clearing. This study aims to assess the impacts of NBS on flood mitigation and soil conservation in Mediterranean mountains. The hydrological responses recorded in 4 experimental catchments located in the Central Pyrenees, along with an analysis of physical-chemical soil properties, form the basis of our investigation.

The hydrological results showed that: (i) land abandonment and the expansion of shrubs and forests (rewilding and afforestation) decrease hydrological connectivity, while tends to increase when shrub clearing occurs; (ii) the runoff coefficient decreases as a result of revegetation; (iii) natural revegetation and afforestation lead to a decline in the frequency and magnitude of floods, as well as peak flows; (iv) however, afforestation has only remarkable effects on small to moderate floods, with less impact in extreme rainfalls. Concerning soil conservation: (i) revegetation promotes the accumulation of soil organic carbon (SOC), but it is a slow process; afforestation can accelerate it, although a high percentage is stored in labile forms; (ii) long-term regenerated grassland, through shrub clearing, accumulates more SOC than shrublands; (iii) afforestation enhances aggregate stability. Sustainable land management based on NBS in Mediterranean mid-mountains should be applied in order to obtain benefits for soil and water conservation in a context of Global Change.

Water is an essential resource for life, supporting human activities from agriculture and industry to domestic use and ecosystem health. However, the world's freshwater reserves are threatened by a variety of factors, including climate change, population growth, and economic development. As a result, freshwater resources of sufficiently high quality are diminishing around the globe and water scarcity is pressuring sectors such as agriculture, industry, and domestic use to compete relentlessly, jeopardising socio-economic stability, growth, and environmental integrity.

One of the solutions to utilize our water resources more efficiently, and to mitigate the effects of water scarcity, is to adopt and implement Nature Based Solutions (NBSs). As NBSs offer actions to protect, sustainably manage and restore ecosystems, they can also contribute to reducing irrigation water use, thus leaving more water resources for the rest of the sectors.

The PRIMA funded project entitled "Learning and action alliances for Nexus environments (LENSES)" (Grant Agreement No: 2041) has explored the impact of applying NBSs such as low tillage, crop rotation, organic manure use, mulching, etc., and their contribution to the water budget improvement in the 6 pilot areas, which are Donana (ES), Tarquinia (IT), Pinios (GR), Koiliaris (GR), Menemen (TR), and Deir Alla (JO). According to the water accounting models developed by the Water Evaluation And Planning System (WEAP) software and supported by the hydrological models such as Hydrologic Engineering Center – Hydrologic Modeling System (HEC-HMS), and Soil & Water Assessment Tool (SWAT), these explored NBSs have simulated as scenarios where the implementations of these NBSs have been applied to the entire extent of the related pilot areas.

The results of the study suggest a significant increase in water use efficiency between 10-25% depending on the NBS application, providing a considerable solution for the decision-makers and stakeholders, not just for mitigating the effects of water scarcity, but also for the sustainable management of agricultural lands and soil-water-human health.

Soil and water degradation is one of the key challenges in the Mediterranean region as well as around the globe. Sectors depending on water resources, most notably rural communities are facing water scarcity mainly aggravated by natural and anthropogenic effects such as climate change, population, and pollution increase, among others. One of the solutions to mitigate the effects of water scarcity is to use water efficiently such as through the use of agro-ecological methods including Nature-based Solutions (NbSs). To ensure the wider uptake and application of NbSs, both the awareness and the capacity of rural communities have to be increased.

Thus, we investigated the current perception of NbSs among the rural communities in five hotspots of land and water degradation in, respectively, Algeria, Egypt, Greece, Lebanon, and Turkey. This was achieved through a Value-Attitude-Perception (VAP) survey which was organized in the context of the PRIMA funded project entitled "Safeguarding the Livelihood of Rural Communities and the Environment in the Mediterranean Through Nature-based Solutions (Mara-Mediterra)" (Grant Agreement No:2121).

To map and evaluate stakeholder perceptions of NbSs, a well-known mapping technique entitled Fuzzy Cognitive Mapping (FCM) is employed. Essentially, FCM is a qualitative soft computing method, introduced in the field of cognitive maps (CM). FCM is a graph-based technique that, like any conventional CM, is made up of concepts and causal connections. The distinction is that in FCM, the relationships between concepts are defined by fuzzy connections and their models are fuzzy sets.

The results of the FCM are based on an aggregate of 467 replies collected to the VAP survey that was conducted across 5 countries, capturing the viewpoint of farmers as end-users of NbSs. The findings bring a valuable means to increase awareness and build capacity towards the wider uptake of NbSs both among farmers, and local water managers, as well as policy- and decision-makers in the agricultural and water sectors.

##### POSSIBILITIES FOR IMPLEMENTATION OF NBS IN RURAL LANDSCAPE FOR SUSTAINABLE MANAGING OF SOIL AND WATER RESOURCES IN VOJVODINA REGION, SERBIA

J. GRABIC <sup>1</sup>, M. VRANESEVIC <sup>1</sup>, Z. SRDJEVIC <sup>1</sup>, S. SEREMESIC <sup>2</sup>

<sup>1</sup> Department of Water Management, Faculty of Agriculture, University of Novi Sad, Novi Sad, SERBIA

<sup>2</sup> Department of Field and Vegetable Crops, Faculty of Agriculture, University of Novi Sad, Novi Sad, SERBIA

It is generally accepted that intensive agriculture contributes to significant changes not only in land use patterns but also to the degradation of soil and water resources within the rural landscape. In recent decades more attention has been drawn to Nature-based Solutions (NbS), encompassing a variety of practices aiming to use natural solutions and processes to reach sustainability, while exploiting soil and water resources.

In the Vojvodina region, Serbia, agriculture represents one of the major economic branches, and simultaneously is a crucial factor which had influenced the reshaping landscape. While arable land occupies around 85% of the territory, only 8% of the area is under protection and the rest is under infrastructure, water bodies, etc. In such circumstances majority of the rural landscape is degraded and there is an urgent need for implementing practices that can lead to its improvement and restoration. Despite that tools and practices promoted by NbS are proven to be effective, both as economically and eco-friendly, lack of flexibility and willingness to implement necessary changes in a wider area seems to be major obstacles concerning the agricultural practice in Vojvodina region. However, there is a niche where implementation of NbS is possible and reasonable, i.e. within protected areas. Some of the successful examples are introducing grazing for suppression of invasive species, building constructed wetlands for wastewater purification for nearby villages, or establishing vegetated filter strips along arable plots and canal networks, etc.

Wider application of NbS within the rural landscape of the Vojvodina region needs to be initiated by official governmental resolutions and further promoted and supported by agriculture extension services. Cross-sectoral cooperation might play an important role, e.g. involving the Ministry of Environmental Protection of the RS, down to local managers of protected areas. Such cooperation would lead to erasing the sharp edges of protected areas and enhancing biodiversity, soil conservation, and sustainable water management in wider arable areas.

Precision irrigation is an essential component of Nature-Based Solutions (NBS) for sustainable agriculture. This synergy among advanced technologies and nature-based solutions aims to optimise the use of water resources while ensuring environmental sustainability. This research as a significant contribution to the understanding of how precision irrigation, as part of Nature-Based Solutions, can promote sustainability and crop resilience in an environment increasingly affected by climate change. In the context of this perspective, we present the results of our experimentation on a field of processing tomatoes. A three-year open field experiment (2021-2023) was conducted in Italy on tomato processing (Var. Durpeel F1). Four different irrigation treatments with drip irrigation were tested: full irrigation (Fi) - (100%), deficit irrigation (Di) - (80%), regulated deficit irrigation (RD<sub>i</sub>) - (60-80-60%) and deficit irrigation (Di<sub>2</sub>) - (60%).

The impact of different irrigation treatments on crop yield and quality was evaluated. In particular, water efficiency indices including water use efficiency (WUE), water use efficiency in total and marketable yield (TYWUE and MYWUE) and water productivity index (IWP) were analysed. The results indicate a high water use efficiency in deficit irrigation treatments with no significant differences compared to full irrigation and a strong correlation between reduced irrigation and tomato quality. This study shown that the adoption of these innovative solutions can maximise water efficiency, reduce waste and mitigate environmental impacts.

Regenerative practices of diversified agriculture, offering additional income, biodiversity enhancement, and climate resilience through improved soil water holding capacity and greenhouse gas storage, faces scepticism in semiarid rainfed climates due to perceived productivity reduction from water and nutrient competition. This work used a field-level intercropping experiment in Murcia (Spain), to evaluate the performance of two regenerative systems (almond-caper; almond-thyme) and compared them to conventional management of rainfed almond crops under different scenarios. Over five years, a large collection of data was gathered to evaluate the impact of the diversified schemes on soil and plant properties. In this work a wide range of soil and plant parameters was adapted in an ecosystem services (ES) framework and a participatory multicriteria analysis (MCA) was used to evaluate the management alternatives in terms of sustainability. Supporting, regulating and provisioning ES and economic indicators were included in an integrated assessment of the three above mentioned agricultural management alternatives. Divided over these ES, there were nine subgroups and thirty-six indicators. A stakeholder consultation allowed to include the perspective of different stakeholders on ES groups and economic indicators in the evaluation.

The almond-thyme diversification offers the best results in the integrated evaluation. On the one hand, it improves the group of provisioning services, including productivity and available water, and the group of regulation services, including climate, hydrological, nutrient cycling and erosion control. Diversification with caper shows the best results in the group of support services including plant and soil biodiversity, soil structural condition and fertility. In the first two years, economic indicators were unfavorable for diversification due to initial investments in labour and installation of secondary crops. From the third year onwards, the profits from the extraction of thyme essential oil increased the direct benefits, offsetting the initial investment. In addition, the application of the new aid from the Common Agricultural Policy favours the introduction of a permanent secondary crop.

##### EFFECT OF OXYTETRACYCLINE AND IRON ON THE TRANSFORMATION OF ARSENIC IN PADDY SOIL

J. GAO, Y. TONG

Institute of Soil Science, Nanjing, CHINA

In order to study the interaction of antibiotics and arsenic contamination in paddy soils, microcosmic culture experiments were carried out in paddy soils, which was sampled from a paddy field in Xiangtan City, Hunan Province. By simulating the flooding-drainage process of paddy field, the effect of oxytetracycline (OTC) on the redox transformation of iron and arsenic was explored. During the flooding stage, the presence of OTC could promote the reduction of iron minerals, and the content of Fe(II) in dissolved, exchangeable and adsorbed/weakly crystalline iron minerals were significantly increased, so more  $\bullet\text{OH}$  radicals were generated in the drainage stage, which further promoted the oxidation of dissolved As(III). OTC had complexing and reducing effects on Fe(III), which could promote the reduction of iron-containing substances in soil. At the same time, as a broad-spectrum antimicrobial agent, the selective effect of OTC increased the relative abundance of dissimilated iron-reducing bacteria, and also promoted the reduction and dissolution of iron minerals. In addition, the relative abundance of sulfate-reducing bacteria increased in the presence of OTC during the flooding stage, which increased the amount of sulfide-bound As, and thus decreased the content of dissolved As. The results of this study indicated OTC could enhance the reduction and dissolution of iron-containing substances in soil during the flooding stage, but reduce the dissolution of As by increasing the amount of arsenic sulfide. In the draining stage, it was conducive to the generation of more  $\bullet\text{OH}$  and the rapid oxidation of dissolved As(III). The coexisting of Fe and OTC reduces the risk of As uptake and transportation in rice.

DECREASE OF RCS TRANSFER FROM SOIL TO PLANT IS DRIVEN BY APPLICATION OF MANURE - DISTINGUISHED ROLES FOR POTASSIUM AND ORGANIC MATTER-

T. SHINANO <sup>1</sup>, M. SUZUKI <sup>1</sup>, H. MARUYAMA <sup>1</sup>, T. WATANABE <sup>1</sup>, K. KUBO <sup>2</sup>

<sup>1</sup> Graduate School of Agriculture, Hokkaido University, Sapporo, JAPAN

<sup>2</sup> Tohoku Agriculture Research Center, NARO, Fukushima, JAPAN

Contamination by radionuclides will be one of the major concerns in initiating agricultural activity after a nuclear accident. Radiocaesium (RCs) dispersed over a large area of Japan after the FDNPP accident and several countermeasures (topsoil removal and/or potassium fertilizer application) were carried out. However, topsoil removal to reduce RCs may lead to a huge amount of discarded topsoil and also lower crop yield due to the loss of fertile topsoil. On the other hand, a huge amount of potassium fertilizer application requires a long time of soil management. This study aimed to assess the effects of cattle manure compost (CMC) application on soil properties, crop growth, and RCs transfer from soil to plant in a physically decontaminated field and pot experiment. Field trials were conducted during 2018–2022, with different CMC applications along with conventional fertilization in 2018–2019 and conventional fertilization alone in 2020–2022 (2019–2020 soybean, 2021–2022 buckwheat). A pot experiment was used to evaluate the impact of CMC application in soil on RCs transfer to Komatsuna. In the field trial during 2018–2019, CMC application exhibited higher soybean shoot dry weight than plots receiving conventional fertilization and additional K fertilizer. The transfer factor of RCs (TF-RCs: plant RCs activity concentration/soil RCs activity concentration) was negatively correlated with soil exchangeable K (Ex-K) as observed in previous reports. During 2020–2022, grain yields were higher in CMC plots than in other plots that received conventional fertilizers, and this indicates that the application of CMC improved the soil fertility. The pot experiment confirmed that CMC application resulted in lower TF-RCs and higher plant DW compared with conventional fertilized soil with the same Ex-K level. Additionally, the soil exchangeable RCs (Ex-RCs) level was significantly lower in CMC soil than in conventional soil. These findings demonstrate the potential of CMC application to improve crop growth and reduce RCs transfer in physically decontaminated fields by increasing the Ex-K level and decreasing the Ex-Cs level of the contaminated soil.

Figure Relationship between exchangeable K (ExK) and transfer factor (TF) of RCs.

##### GLYPHOSATE APPLICATION MODIFIES THE TRANSFER OF TRACE ELEMENTS FROM SOILS TO SOIL SOLUTIONS AND PLANTS

N. BEMELMANS, R. DEJARDIN, B. ARBALESTRIE, Y. AGNAN

Earth and Life Institute, UCLouvain, Louvain-la Neuve, BELGIUM

The dynamics of trace elements in the soil-plant system is governed by multiple parameters, including chelating organic compounds originating from both organic matter and pesticides such as glyphosate. To evaluate the influence of glyphosate on the mobility of trace elements, we performed a greenhouse experiment considering four modalities: a control without any application, two modalities with different glyphosate doses, and one with an addition of compost in the soil to evaluate its potential influence to mitigate the glyphosate impact on trace element mobility. These modalities have been applied on four soils: one uncontaminated, two contaminated by human activities, and one naturally contaminated. We followed both trace element and glyphosate concentrations in the soil solution over time and trace element concentrations in plants at the end of the experiment. Results showed that, even though glyphosate concentrations quickly decrease in soil solutions, there was an effective influence of glyphosate on the transfer of trace elements to both soil solutions and plants. However, this influence was highly dependent on both, elements and soils considered. For example, Mn, Co, Zn, Mo, and Pb were especially more mobilized to soil solution with glyphosate in the uncontaminated soil. This influence decreased along the soil contamination gradient. The same observation was done for trace element transfer from soil to plants. The influence of compost on the transfer of trace elements to plants is unclear. Nevertheless, compost can either enhanced the transfer of trace elements to soil solutions in uncontaminated and naturally-contaminated soil or decreased the transfer in anthropogenically-contaminated soils. It thus appears that glyphosate could increase the exposure of trace elements through food consumption and their transfer to the ecosystem, particularly in uncontaminated and weakly contaminated soils. In highly contaminated soils, compost can diminish the glyphosate-induced enhancement of trace element mobility to soil solutions.

##### SOIL PHYSICS STUDIES WITH NON-AQUEOUS PHASE LIQUIDS

A. MAKÓ<sup>1</sup>, H. HERNÁDI<sup>1</sup>, G. BARNA<sup>1</sup>, Z. BAKACSI<sup>1</sup>, V. LABANCZ<sup>2</sup>, M. KOCSIS<sup>1</sup>, K. RAJKAI<sup>1</sup>

<sup>1</sup> HUN-REN, Centre for Agricultural Research, Institute for Soil Sciences, Dept. of Soil Physics and Water Management, Budapest, HUNGARY

<sup>2</sup> Hungarian University of Agriculture and Life Sciences, Institute of Environmental Sciences, Department of Soil Science, Gödöllő, HUNGARY

Soil physics studies with non-aqueous phase liquids (NAPLs) can have practical implications other than environmental ones. Since, unlike water, these liquids do not (or only to a limited extent) exert a dispersing, disaggregating effect during the saturation of soil samples and during measurements, they can be successfully used in soil structure studies.

The use of laser diffractometry (LDM)-based particle size distribution analysis in the study of aggregate stability (AS) in soils is a promising new methodological option, but is not yet routinely applied. LDM AS measurements offer the possibility to study the aggregate segregation processes as a function of time or input energy and can be used to investigate the role of the dispersant (e.g. water and NAPL) quality in AS. Determination of the NAPL retention in soils based on commonly used prediction methods is rather questionable due to the different phase interactions in air/liquid/soil systems. These interactions lead to different pore size distributions in water and NAPL saturated soil systems and can cause large variations in hydrophysical parameters.

In our research, we used soil samples and test results from the Hungarian Soil Structure Database (HunSSD). LDM AS measurements were performed with the Malvern Mastersizer 3000. Water and NAPL retention measurements were performed with modified pressure plate extractors. The NAPL used for the measurements was the model fluid Dunasol 180/220.

In this presentation, we will show the experience of AS and retention measurements with the two fluids, the comparison of pore size distributions calculated from retention curves, and their relationship with other soil properties.

This research is supported by the Hungarian National Research, Development and Innovation Office Foundation (Grant No. OTKA K134563) and by a common grant from the Hungarian and Polish Academy of Sciences (Grant No. NKM 2019-17).

Soil phosphorus (P) pool is intimately connected to soil organic matter (SOM), especially mineral-associated organic carbon (MAOC). However, the relationship and mechanism between MAOC fractions and P fractions and their response to fertilization remain unclear. Based on a long-term (21- and 29-year) field fertilization trial in black soil, organo-mineral complexes (< 20 μm) were separated and the chemical properties, MAOC fractions, P fractions, P species and P sorption were analyzed. Compared to no-fertilizer control, chemical fertilizer resulted in soil acidification (soil pH 6.15–6.27), increasing the contents of the MAOC fraction bound to minerals by weak linkages in complexes. Straw addition maintained soil pH at 7.53–7.84, and the contents of some MAOC fractions (which were remaining water-soluble, bound by cations, encapsulated by resistant carbonate, and insoluble Humin) were significantly higher than that of chemical fertilizer alone. Fertilization increased total P contents in complexes, with chemical fertilizer mainly increasing highly labile P (Resin-Pi, NaHCO<sub>3</sub>-Pi, NaHCO<sub>3</sub>-Po, and NaOH-Pi) and straw addition mainly increasing Di. HCl-Pi of moderately labile P. Correlation analysis showed that the increased and dominant MAOC fractions were significantly positively correlated with the increased P fractions. XANES spectroscopy further revealed that chemical fertilizer increased the proportion of AlPO<sub>4</sub>, suggesting that MAOC promotes the retention of labile P via association with Al under weakly acidic conditions. Straw addition increased the proportion of Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> and Ca<sub>5</sub>(PO<sub>4</sub>)<sub>3</sub>OH; moreover, it also increased the maximum P sorption capacity of complexes, suggesting that MAOC enhances P sorption via association with Ca under weakly alkaline conditions and that adsorbed P will transform into more stable Ca-associated P. Our findings demonstrate that MAOC promotes P accumulation via association with different P fractions, and these processes are mineral and pH-dependent. This information may be useful for managing and regulating P in agriculture.

##### SOIL REHABILITATION SHAPED DIFFERENT PATTERNS OF BACTERIAL AND ARCHAEOAL COMMUNITY IN AMD-CONTAMINATED PADDY SOIL

C. GUO

SOUTH CHINA UNIVERSITY OF TECHNOLOGY, GUANGZHOU, CHINA

Long-term contamination of cultivated land with Acid Mine Drainage (AMD) has inevitably ratcheted up soil acidity and resulted in the enrichment of toxic metals and sulfate from contaminated rivers, thereby reducing the large scale of arable land and causing the appearance of environmental disaster zones. Microbial communities play a critical role in nutrient elements cycles and ecosystem functions. Microorganisms are essential for soil rehabilitation and long-term sustainability of established plants. However, the recovery process of microorganisms in AMD-contaminated paddy soil is poorly understood at present. To verify this, we sampled AMD-irrigated paddy soils before at different rehabilitation stages by characterizing bacteria and archaea community from AMD-contaminated rehabilitation to pre-disturbance levels from references sites. Next-generation sequencing is used to describe shifts in diversity and taxonomic composition of bacterial and archaeal. Co-occurrence networks are constructed to reveal potential microbial interaction patterns. The result showed bacterial community followed an observable taxonomic transition overtimes, with community structure becoming more similar to that of unmined reference sites. But the archaeal community only showed a seasonal change, which may hint that the archaeal community needs more time in rehabilitation. Both bacterial and archaeal community composition changes were apparent at high taxonomic levels, bacterial communities become dominated by Proteobacteria phylum, and archaeal community was dominated by Crenarchaeota, we proposed the possible reason is bacterial community were mainly derived by soil pH while the archaeal community was impacted by heavy metal. The bacterial co-occurrence networks increased in complexity during succession, improving the community's resistance to environmental disturbance, while the archaeal did not change monotonically with time. This study highlights the distinct recovery pattern of the bacterial and archaeal community during AMD-contaminated paddy soil rehabilitation, which provides a deep understanding of their role in paddy soil, and subsequent harnessing of their potential to pave the way in future rehabilitation strategies for mined sites.

**THE IMPACT OF ARABLE SOIL MANAGEMENT ON PHYSICAL SUBSOIL FUNCTIONS- THE RATIO OF AIR CAPACITY AND AIR PERMEABILITY OR HYDRAULIC CONDUCTIVITY IN SUBSOILS AS A DOCUMENT OF HARMFUL SOIL DEGRADATION.**

R. HORN, H. FLEIGE

Institute of Plant Nutrition and Soil Sciences, Kiel, GERMANY

The development of increasingly powerful and increasingly heavy agricultural machinery helped to enhance the soil management effectivity on even increasing field sizes and to increase crop yields manifold, while the soils and their limited resilience and pore functionalities were mostly ignored. Zink et al. (2010) developed the Compaction Verification Tool (CVT) as a physical property, which defines the compaction status and its consequences for plant growth, ground water recharge and aeration by the linked functional indicators: air capacity AC and saturated hydraulic conductivity  $k_s$ . They defined the optimal soil conditions (class I) by  $k_s > 10 \text{ cm/d}$  and  $AC > 5 \text{ Vol } \%$ . Class II and III define conditions where either the  $k_s$  or the AC are smaller than the limit. Class IV finally includes all soils or soil horizons (topsoil and especially the subsoils) where both functions are smaller than the critical ones (class I). Based on more than 500 soil profile data down to 100cm depth we could proof, that in subsoils with  $< 25\%$  clay show 32% and 40% of all subsoils with  $> 25\%$  clay critical site conditions. The time dependency can be derived from the pattern changes both for the top- and subsoil. While during the period 1980 – 1999 showed only a few sites already Class IV conditions in subsoils, increased the number of sites with Class IV properties intensely during the period 2000-2019. Especially Luvisols are very sensitive under conventional soil management both for top- and subsoil horizons. The dependency upon soil aggregate types for all soil profiles reveals especially for subsoil horizons with coherent and prismatic structure mostly class IV ratios, while in polyhedral and subangular blocky structured subsoil horizons are more sites in a favorable state, but Class IV conditions increase with time, too. Most prominent are the sites with a platy structure in subsoils gathered in class IV with a growing proportion in the last 2 decades.

#### EVIDENCES FOR PARENT MATERIAL'S REGULATION OF MICROBIAL COMMUNITY AND ORGANIC MATTER FORMATION IN INITIAL SOIL DEVELOPMENT

K FUJII<sup>1</sup>, C HAYAKAWA<sup>2</sup>, T KOSAKI<sup>3</sup>

<sup>1</sup> Forestry and Forest Products Research Institute, Tsukuba, JAPAN

<sup>2</sup> Utsunomiya University, Utsunomiya, JAPAN

<sup>3</sup> Aichi University, Nagoya, JAPAN

Soil develops through interaction of biotic (plant and microbes) and abiotic components (minerals). Importance of microbial necromass to formation of soil organic matter and aggregates has been well documented, while it is still unclear whether mineral type determines microbial community composition and pathway of soil development. Mineral powder samples [granite, basalt, andesite, sandstone, kaolinite, hydrohalloysite, Akahoya volcanic ash (7300 years old), Sakurajima volcanic ash (fresh)] in nylon mesh bags were buried in Southwest Japan (Okinawa and Amami islands) and recovered 0.5, 1.5, 10, 20, 40 years after burial. We measured changes in bulk density, C and N concentrations, pH, element composition, particle size distribution, specific surface area, microbial community diversity (Shannon, prokaryote and fungi), and 32 enzyme activities (Ecoplate). The pH and acid-neutralizing capacity (ANC) decreased with time for the respective mineral species, with the higher rates in granite and Sakurajima volcanic ash. No increases in clay contents were found, but increases in short-range-order minerals contributed to C accumulation in volcanic ash and andesite. Microbial diversity increased with increasing soil C concentrations to reach saturation at the level close to the bulk soil. Enzyme activities increased with microbial diversity at the early two years, then they decreased with decreasing pH. We demonstrated that specific surface area of mineral species shape microbial composition and that pH or ANC regulates decomposition activity and soil organic matter formation.

DEEP NITRATE ACCUMULATION IN RELATION TO SURFACE SOIL MANAGEMENT VERSUS REGOLITH INTERACTIONS IN A HIGHLY WEATHERED SUBTROPICAL CRITICAL ZONE

S. YANG, H. WU, X. SONG, G. ZHANG

Institute of Soil Science, Chinese Academy of Sciences, Nanjing, CHINA

Nitrate accumulated deep (>100 cm) in the regolith threatens groundwater quality, but most studies focus only on nitrate nearer the surface (<100 cm). Surface soil management versus regolith interactions affect deep nitrate leaching, but their combined impact remains unclear. This study investigated how deep nitrate accumulation was affected by land use type, landscape position, crop planting years, regolith structure, and soil properties in highly weathered subtropical red soils. Deep nitrate storage varied from 43.6 to 1116.3 kg ha<sup>-1</sup>. Nitrate concentrations in the deep horizons of cropland and orchard regoliths were significantly larger than those in the paddy fields or woodland (p < 0.05). When compared to the regoliths from the upper slope of the cropland, those from the middle slope stored significantly more nitrate in the deep regolith layer (p < 0.05). Nitrate accumulation generally increased with the planting years. The difference in peak nitrate concentration (9.0–20.0 mg kg<sup>-1</sup>) with planting year gradient (3–58 years) varied by 2.2 times, and the difference in nitrate storage (43.6–425.7 kg ha<sup>-1</sup>) varied by 9.8 times. Regolith thickness was positively correlated with nitrate storage (R<sup>2</sup> = 0.43, p < 0.05). Reticulated red clay (110–838 cm) had 81% of the accumulated nitrate and overlapped with 79% of the nitrate accumulation layer. Texture and pH explain 41.6% of the variation in nitrate concentration. As surface soil management practices interact with deeper regolith to control the spatial pattern of nitrate accumulation, vulnerable regions could be identified to avoid high accumulation. This study shows that internal hydrogeological conditions determine fundamentally solute transportation and consequently environmental functions.

Little is known about how soil depth affects the presence of arbuscular mycorrhizal fungi (AMF). AMF communities in deeper soil horizons can harbour a unique pool of biodiversity and can also contribute to carbon sequestration.

In our study, we chose an alkaline grassland site in a rural region of the Great Hungarian Plain. The grassland is in regenerative agricultural practice. A soil survey was conducted in August 2023, resulting in a precision-scale digital soil map of the area. The survey sampled soil horizons from 13 different soil profiles. The soils were classified according to the rules of the WRB system. The samples were processed and a full physical and chemical analysis of the soils in the sampling area was carried out.

Trap plants were planted in the soil samples taken during the soil survey. The percentage of root colonisation was determined. By examining the colonisation capacity of different soil horizons, we could show which soil properties have a significant effect on the presence of AMF. We can also see how AMF colonisation capacity varies within the soil profile, giving us a better understanding of how depth affects AMF communities.

By extending our research below the A horizon of soils, we can show how biodiversity varies across soil types and how biodiversity changes with depth. The results can shed light on the function and role of AMF communities in deeper soil horizons.

<sup>5</sup> Institute of Earth Sciences, Academia Sinica, Taipei, TAIWAN

A humid soil chronosequence (1.5 to 1070 ka) was investigated on the Galápagos Islands. Indices of chemical weathering, e.g. the Chemical Index of Alteration correlated well with indicators of pedogenic development, such as solum thickness, soil pH, or the ratio of oxalate- to dithionite-extractable Fe. We found considerable loss of base cations already in the early to intermediate phases of weathering (e.g. 95% of Na and 78% of Mg lost from the topsoil after 26 ka) and almost complete loss from the entire profile in soils older than 800 ka. However, we also observed topsoil gains of Ca, K, and P in the young to intermediate-aged soils (<=26 ka), which are likely due to biological uplift, i.e. root uptake from less weathered subsoil layers, transport to above-ground plant parts and deposition onto the topsoil via litterfall. The topsoil gain of P was especially pronounced (around 200%) at the youngest sites (1.5 and 4.3 ka) and that of K was prominent at the next oldest site (26 ka). This element selectivity seems to be linked to the different capacity of the soils to retain P and K, respectively, once uplifted into the topsoil. The young (andic) soils are dominated by short-range-order secondary phases (allophane, ferrihydrite), which show very high phosphate retention capacity. After 26 ka of pedogenesis, vermiculitic phases have become predominant. These have much less P retention capacity but a high propensity to fix K in their interlayers, leading to illitization (Figure 1). Our results suggest that young volcanic surfaces experience high rates of chemical weathering and pedogenesis. However, biological uplift of nutrient elements may reverse elemental weathering losses and decelerate weathering rates at early to intermediate pedogenic stages. In this process, secondary minerals act as element-specific binding agents effectively retaining biologically uplifted nutrients in surface soils. As such, these constituents are not only products of chemical weathering reactions, but can themselves strongly alter biogeochemical element cycling and weathering rates.

Figure 1. Stacked X-ray diffractograms of intermediate-aged profile (26 ka; clay fraction; Mg-saturated and air-dried) showing a peak shift from 1.4 nm in the subsoil to 1.0 nm in the topsoil, indicative of the illitization of vermiculitic phases.

#### ANTHROPOGENIC INFLUENCE ON THE PEDOGENESIS OF VOLCANIC SOILS IN SOUTHERN CHILE

B. HENRÍQUEZ CAURAPAN<sup>1</sup>, F. Z.<sup>2</sup>, F. O.<sup>3</sup>, S. V.<sup>4</sup>

<sup>1</sup> Universidad Austral de Chile, Escuela de Graduados, Facultad de Ciencias Agrarias y Alimentarias, Valdivia, CHILE

<sup>2</sup> University of Natural Resources and Life Sciences, Department of Forest and Soil Sciences, Institute of Soil Research, Vienna, AUSTRIA

<sup>4</sup> Universidad Austral de Chile, Instituto de Ingeniería Agraria y Suelos, Centro de Investigación en Suelos Volcánicos (C, Valdivia, CHILE

In southern Chile, volcanic ash has undergone distinct evolution compared to other regions, influenced by high rainfall and humid conditions fostering the formation of short-range ordered (SRO) minerals like allophane, imogolite, and Al/Fe humus complexes. These unique soils, originally forested, have increasingly been repurposed for grasslands and croplands. Our study aimed to discern the human-induced impact on the colloidal composition of volcanic ash-derived soils in this region.

Characterization and sampling encompassed four soil types (Typic Hapludult, Acrodoxic Duraquand, Typic Paleudults, and Duric Hapludand) under different land uses: forest, cropland, grassland, and eucalypt plantation. Differential extractions using pyrophosphate and oxalate were employed to assess changes in the amorphous colloidal fraction and x-ray diffraction was conducted to identify crystalline clays. Under grassland and plantation use, the colloidal fraction exhibited dominance of SRO minerals, augmenting  $Al_0 + \frac{1}{2}Fe_0$  and  $Al_p/Al_0$  contents, leading to altered characteristics in Acrodoxic Duraquand. The pH range of 5 to 7, coupled with limited complexing organic compounds, facilitated the formation of Al polymers interacting with silica to generate allophane/imogolite. Clay mineral compositions was less affected by land use but varied by volcanic soil type, with Typic Paleudults displaying a higher proportion of crystalline clays linked to longer pedogenic evolution.

Paleudults, derived from Pleistocene volcanic ash on metamorphic rocks, exhibited contamination from Holocene volcanic ash, containing amorphous materials. Typic Hapludult and Duric Hapludand showcased minimal development of crystalline clays, primarily secondary chlorite, alongside increased gibbsite presence at depth. Acrodoxic Duraquand, while sharing similar mineral compositions with the aforementioned soils, showed increased crystalline mineralogy in croplands, with kaolinite and illite potentially stemming from mica weathering. The increased mineral presence might originate from a geomorphological influence mixing materials from a neighboring estuary. However, an anthropogenic effect cannot be discounted, considering the soils' history under plantations for five decades before cropland, contributing to chemical and physical alterations.

**WEATHERABLE PRIMARY MINERALS IN JAPANESE AGRICULTURAL SOILS DETERMINE MULTIPLE SOIL PROPERTIES**

K. KUROKAWA <sup>1</sup>, A. NAKAO <sup>1</sup>, A. SUZUKI <sup>1</sup>, K. AZUMA <sup>1</sup>, S. TANAKA <sup>2</sup>, J. YANAI <sup>1</sup>

<sup>1</sup> Graduate School of Life and Environmental Sciences, Kyoto Prefectural University, Kyoto, JAPAN

<sup>2</sup> Faculty of Agriculture and Marine Sciences, Kochi University, Kochi, JAPAN

Primary minerals are major components of soil, but their spatial variations and contributions to soil properties are not clear due to insufficient quantitative information. The objective of this study was to quantify primary minerals with improved precisions and to better understand the linkage between primary mineral variations and soil properties under different climate conditions in Monsoon Asia.

Soil samples (0–15 cm depth) were collected widely from agricultural fields in Japan (n = 79), Taiwan (n = 16), and Thailand (n = 16), mostly belonging to temperate (Köppen climate classification: Cfa, Dfa, and Dfb), subtropical (Aw and Cwa), and tropical climate (Aw), respectively. The mineral composition of air-dried, 2 mm-sieved soils was obtained from the X-ray powder diffraction (XRPD) data by full-pattern summation method using self-prepared reference library of standard XRPD patterns. The nonexchangeable K content was obtained by subtracting exchangeable K content extracted with 1 M ammonium acetate from phytoavailable K content extracted with 1 M hot nitric acid.

On average, Japanese soils showed higher plagioclase content (Japan: 23.8, Taiwan: 13.8, Thailand: 4.4 wt.%) and trioctahedral mica content (Japan: 0.3, Taiwan: 0.0, Thailand: 0.0 wt.%) in contrast to lower quartz content (Japan: 28.5, Taiwan: 58.5, Thailand: 65.7 wt.%) than those of other regions. Reflecting these abundances of weatherable minerals, Japanese soils showed the highest positive correlation between sand and plagioclase content ( $r = 0.48$ ,  $p < 0.001$ ) and the highest nonexchangeable K content per mica content. Compared with Taiwan and Thailand where major micas were highly-resistant dioctahedral type (e.g., illite and muscovite), weatherable trioctahedral micas (e.g., biotite and phlogopite) remained in Japanese soils. Higher ability to supply K from micas is a key to reduce chemical fertilizer application rate, and especially in Japan, contribute to reduce food contamination by radiocesium. In conclusion, the improved precisions of the mineral quantification revealed that Japanese soils were abundant in several weatherable primary minerals, each of which determined different type of soil properties.

#### A STUDY OF THE MAGNETIC PROPERTIES OF GOETHITE FROM SOILS AND SYNTHETIC ANALOGS

T. BERQUO<sup>1</sup>, B. KLAUSE<sup>1</sup>, A. MIDDENDORF<sup>1</sup>, G. WYLLIE<sup>2</sup>

<sup>1</sup> Concordia College - Department of Physics, Moorhead - MN, USA

<sup>2</sup> Concordia College - Department of Chemistry, Moorhead - MN, USA

Goethite ( $\alpha$ -FeOOH) is, by far, the most common oxyhydroxide present in soils, occurring ubiquitously around the globe, predominantly in cold to temperate and humid climates. In nature, goethite can be formed basically in two ways (1). In the first route, Fe+2 is released from compounds such as Fe silicates, carbonates, or sulfides, then oxidized in an aerobic environment or from previously existing Fe+3 oxide phases. In such conditions, the goethite formed will mirror the primary Fe distribution of the environment. In the second pathway, the formation involves the presence of ferrihydrite that converts to goethite (1). The magnetic properties of goethite reflect its formation process and its Néel temperature can vary from 330K to 393 K, and correlates with factors like crystallinity, isomorphous substitution, the content of excess water, and cation vacancies (2, 3, 4).

Goethite present in soils was investigated by using curves magnetization temperature (50 K to 1000 K) and field dependent (hysteresis loops), and Mössbauer spectroscopy at room temperature. In addition, we investigated the impact that the substitution of varying amounts of aluminum, nickel, and chromium has on the magnetic properties of laboratory-prepared samples of goethite. The magnetic results of the synthetic samples identified the phases precipitated and the nature of their magnetic behavior, showing also an important particle size effect. Some samples showed a minor contribution of hematite. The information obtained from laboratory-prepared samples helps the investigation and understanding of goethite present in soils.

#### **PALAEO-SOILSCAPE PROXIES FOR PAST GROUNDWATER TABLE ELEVATIONS: A CASE STUDY FROM THE KLEINE NETE VALLEY, NORTHEASTERN BELGIUM**

K. BEERTEN

SCK CEN, Mol, BELGIUM

This investigation explores the use of podzol horizon morphology as a proxy for reconstructing groundwater table (GW) dynamics in interfluvial lowland landscapes in temperate western Europe. In the absence of peatlands on such interfluvies, traditional proxies for GW table reconstruction, such as palynomorphs, testate amoebae, and C/N isotopes, are often challenging to employ in these settings. To overcome these limitations, this study adopts podzol morphology as a key indicator for past groundwater table elevation. A novel approach will be presented in which past GW estimates from podzol morphology are tested against additional palaeo-soilscape features such as aeolian deflation and/or sedimentation, or rare local peat development in depressions. Previous research has employed podzols for GW table reconstruction, primarily relying on area-wide databases. The current study, however, is based on detailed field investigations on two interfluvies within the Kleine Nete valley, northeastern Belgium. The research integrates fieldwork data with basic granulometric and geochemical analyses, radiocarbon dating, optically stimulated luminescence (OSL) dating, and palynology.

The results reveal the presence of dry podzol morphology in higher elevations, which are typically covered with aeolian sand deposited in dry conditions. Past wind deflation phenomena here align with expected deeper past GW tables at such drier sites. Wet podzol morphology is observed in lower landscape positions, and these palaeosoils tend to occupy depressions. Here, erosional phenomena are absent, and the depressions are typically filled with drift sand that was deposited in wet conditions, showing lacustrine-like features. Ultimately, the deepest depressions show the development of peat.

Chronological analysis through OSL dating of drift sand, radiocarbon dating of A-horizons, peat, and Bh-horizons places the development of these podzols between approximately 8000-1500 BP, while drift sand accumulation took place in the period between approximately 3000-200 BP. A comparison with present-day GW elevation data reveals that all past GW table estimates exceed current levels. This study underlines the importance of considering podzol morphology in GW table reconstructions.

**Keywords:** palaeosoils, podzol horizon morphology, drift sand facies, aeolian deflation, geochronology

#### ISOTOPY, MICROMORPHOLOGY AND COMPOSITION OF PEDOGENIC GYPSUM IN LOESS-PALAEOSOL SEQUENCES IN THE EBRO VALLEY AS A COMBINED PALEOENVIRONMENTAL PROXIE

D ALVAREZ MORALES <sup>1</sup>, E PLAYÀ <sup>2</sup>, O ARTIEDA <sup>3</sup>, R M POCH <sup>1</sup>

<sup>1</sup> University of Lleida, Lerida, SPAIN

<sup>2</sup> University of Barcelona, Barcelona, SPAIN

<sup>3</sup> University of Extremadura, Plasencia, SPAIN

The loess palaeosol sequences in the Ebro valley are associated with arid and semi-arid climates where the main pedogenic process is the mobilisation of carbonate and gypsum through the soil, resulting in secondary accumulations. In this arid climatic context, the conservation of palaeoenvironmental indicators of biological origin is very limited and therefore, the development of new tools to help us to understand more about conditions of the past is essential.

This study has consisted in the micro-sampling and analysis of secondary gypsum accumulations from five Loess Primary Sequences (LPS) applying several approaches and analytical techniques, in order to understand which processes and palaeoenvironmental conditions gave place to their development and preservation. Traditional methods based on the study of gypsum morphologies supported by micro-morphological study have been applied, which has allowed us to observe a variety of crystalline shapes as well as different growths and mineral arrangements. In addition, more novel analyses in the field of pedogenic gypsum have been implemented, including the stable isotopic composition of the sulphate ( $\delta^{34}\text{S}$ ,  $\delta^{18}\text{O}$ ) and crystallisation water ( $\delta^2\text{H}$ ,  $\delta^{18}\text{O}$ ) of gypsum and trace element composition ( $^{137}\text{Ba}$ ,  $^{88}\text{Sr}$ ,  $^{23}\text{Na}$ ,  $^{38}\text{K}$ , and  $^{24}\text{Mg}$ ).

From this study it has been possible to relate pedogenic gypsum with possible source areas, to identify some processes that favour its formation (precipitation in saturated or non-saturated conditions) and how this mineral varies its behaviour throughout the profile (dissolution – reprecipitation in an open environment or closed system fractionation).

The combination of different methods has confirmed that pedogenic gypsum is a potential tool for palaeoenvironmental knowledge in arid and semi-arid regions. However, due to the limitations it presents (solubility, relatively low stability under normal conditions...), it is recommended to combine additional techniques and proxies to be used as an effective palaeoenvironmental proxy.

**Keywords:** Pedogenic gypsum, Micromorphology, Stable isotopes, Paleoenvironmental indicator

#### THE BAIX LOESS-PALAEOSOL SEQUENCE (RHÔNE RIFT VALLEY, SE-FRANCE): A UNIQUE RECORD OF THE TRANSITION ZONE BETWEEN CENTRAL AND SOUTHERN EUROPE

D. SAUER<sup>1</sup>, N. PFAFFNER<sup>1</sup>, A. KADEREIT<sup>2</sup>, V. KARIUS<sup>3</sup>, T. KOLB<sup>4</sup>, S. KREUTZER<sup>2</sup>

<sup>1</sup> University of Göttingen, Department of Physical Geography, Göttingen, GERMANY

<sup>2</sup> University of Heidelberg, Institute of Geography, Heidelberg Luminescence Laboratory, Heidelberg, GERMANY

<sup>3</sup> University of Göttingen, Department of Sedimentology and Environmental Geology, Göttingen, GERMANY

<sup>4</sup> University of Giessen, Department of Geography, Giessen, GERMANY

Loess-palaeosol sections (LPS) provide valuable archives of Quaternary palaeoenvironmental changes over time, and spatial palaeoenvironmental gradients during the same period.

Here we present the LPS Baix, located at the western edge of the Rhône Rift Valley in southeastern France, at 44°42'36" N and 4°43'21" E. Already discovered in 1934, this 14 m thick LPS has never been studied employing modern analytical methods.

It caught our attention because it is located in the transition zone between the presently temperate and the Mediterranean region of Europe. To our knowledge, no LPS has been analysed yet in such a transitional climatic position. It likely provides a missing link between the rigorously analyzed LPS in the presently temperate regions further north (e.g., in northern France, the Alsace region and Germany) and the LPS in the Mediterranean region (e.g., in southern France, Catalonia, Italy and Croatia). Therefore, we aimed at deciphering the paleoenvironmental record of the LPS Baix in this particular transitional climatic position, and analysed the LPS Baix by means of palaeopedological methods combined with OSL dating.

Reddish Btg horizons of a Stagnic Luvisol at the base of the LPS represent the remains of an Eemian to Early Würmian (MIS 5) pedocomplex formed under warm and - at least temporarily - relatively moist conditions. Two brown Bw horizons of truncated Cambisols have been preserved in the overlying early to middle Pleniglacial (MIS 5a/4 and MIS 3) deposits. The upper Bw horizon is associated with large carbonate nodules, indicating that considerable amounts of calcium carbonate were leached from the former middle Pleniglacial Cambisol and accumulated in the underlying loess unit. This truncated middle Pleniglacial Cambisol is very similar to the middle Pleniglacial palaeosol remains in the LPS Collias that we investigated 87 km further south, near Nîmes, in the present Mediterranean climate. No palaeosols were observed in the late Pleniglacial deposits of the LPS Baix.

**Keywords:** loess-palaeosol sequence, Late-Pleistocene, Eemian soil, MIS3 soil

<sup>5</sup> Department for Innovation in Biological, Agro-food and Forest systems DIBAF - University of Tuscia, Viterbo, ITALY

<sup>6</sup> Department of Agricultural and Food Sciences, University of Bologna, Bologna, ITALY

The Sermugnano sequence (Central Italy) is constrained on the top by the pyroclastic flow deposit of "Nenfro" (approx. 505 ka) and at the bottom by the pumice fall deposits of the Paleovulsini phase of activity (approx. 589 ka). In all paleosol horizons, selective extractions of Fe, Al and Si forms highlighted an andic index (oxalate extracted  $Al_{ox} + 0.5 Fe_{ox}$ ) always below 0.4%, indicating neither andic nor vitric properties. They thus do not match the requirements for Andosols classification, as confirmed by the low (0.6-1.3%) contents of allophane and imogolite. The pyrophosphate extractable Al and Fe contents were always low, indicating the scarce presence of Al-Fe/humus complexes.

Two major paleosols have been recognised in the sequence, based on their differences in terms of geochemical composition, forms of oxi-hydroxides, mineralogical and micromorphological properties. The SER1 paleosol (first 0-100 cm), with respect to SER2 (100-210 cm), is featured by i) higher content of monovalent and divalent metal oxides (9.4% vs 6.6%), ii) lower Fed (Na-dithionite extractable)/Fet (total) ratio (0.04-0.09 vs 0.11-0.14), iii) lower Alt/Sit (around 0.4 vs 0.5-0.7), iii) higher Fet/Alt (0.45-0.64 vs 0.21-0.36). All data are consistent with a lower development of SER1 than SER2.

This hypothesis is confirmed by the optical microscopy and SEM analyses, evidencing a prevalent massive soil structure, presence of weakly weathered lava rock fragments and minerals in SER1, while prismatic soil structure, Fe-Mn segregations in the soil matrix and in pores were visible in SER2. Moreover, the clay fraction of SER1 has a mineralogy dominated by swelling phyllosilicates (e.g. smectite), with minor amounts of illite and traces of kaolinite, while SER2 is dominated by illite, and smectites are only present as mixed layers. However, despite the long-time of pedogenesis, all these paleosols are surprisingly poorly developed.

#### PEDOSSEDIMENTS IN THE KARSTIC SYSTEMS OF THE YUCATAN PENINSULA

Y. RIVERA URÍA<sup>1</sup>, S. SEDOV<sup>1</sup>, E. SOLLEIRO REBOLLEDO<sup>1</sup>, J. DÍAZ ORTEGA<sup>1</sup>, H. SALGADO<sup>2</sup>, H. BARBA MEINECKE<sup>3</sup>, R. LÓPEZ MARTÍNEZ<sup>1</sup>

<sup>1</sup> Instituto de Geología, Universidad Nacional Autónoma de México, City, MEXICO

<sup>2</sup> Posgrado de Ciencias de la Tierra, Universidad Nacional Autónoma de México, City, MEXICO

<sup>3</sup> Subdirección de Arqueología Subacuática, INAH-SAS, City, MEXICO

The geology of the Yucatan Peninsula is made up of limestone that is in constant dissolution, forming the so-called karst landscape. This system presents undulating reliefs and depressions with cave systems promoted by karstification that can develop sinkholes and closed depressions that, depending on the thickness of the rocks, can collapse. In the case of surfaces, the solution may present connection points with the caverns. Therefore, karst dynamics can promote depression sites where soils accumulate or erosion sites and subsequent accumulation within the caverns. This work presents comparative results of the jungle soils and pedosediments of the caves that are part of the karst systems within the Playa del Carmen-Tulum transect about 20 km from the coastline.

The soils on the surface that support the jungle of the Peninsula include Réndzic Leptosols, which are characterized by having a lot of organic matter and being shallow, and Chromic Luvisols filling in karst pockets, soils with high clay content.

The caverns "8 Balas" and "Garra Jaguar" have multiple entrances and occasionally small altars are located especially inside Garra Jaguar it is very common to find stoves and small coals produced by burning, so these caves present evidence of Maya occupation.

On the other hand, within these two caverns, approximately 200 meters from the entrances, there are reddish pedosediments with characteristics of Luvisol-type soils, in addition to having very thin A/B/C horizons identified. The origin of these pedosediments is a consequence of vertical type erosion ("soil piping") that can occur in the area due to the cavities resulting from limestone dissolutions, which is why the roots can have connections from the surface and reach the pedosediments and water of the caves.

With this evidence, it can be determined that soil erosion and movement can occur naturally within the karst system but can also be dramatically accelerated due to ancient activities, especially the Mayan people who are known to have heavily populated the area.

<sup>3</sup> Department of Geosciences, University of Padova, Padova, ITALY

Hyperarid soils in deserts are characterized by secondary accumulations of soluble salts (gypsum and halite) in diagnostic horizons due to limited water availability. These soils are termed Reg and classified as Aridisols (Gypsids/Salids). The sources of the pedogenic salts are atmospheric dust and rainwater. In such extreme environments, the interplay between climatic properties, dust flux, and soil properties governs the depth and content of these salt horizons. However, the controls of these climatic properties on the accumulation of pedogenic salts are poorly constrained. To better understand these relationships, we constructed a compartment model that simulates pedogenic gypsum accumulation at millennia timescales at daily time steps. The model was used to quantify the range and sensitivity of climatic factors and dust flux on the accumulation of pedogenic gypsum and estimate the most likely climatic scenarios that could have led to the formation of the diagnostic gypsic horizon developed in Reg soils, Negev desert, since the Late Pleistocene (<65 ka). Input parameters are stochastically simulated rainstorms, potential evapotranspiration (PET), dust flux, and sulfate concentration in rainwater. The model was calibrated using data from early Holocene soil profiles, assuming that the climate during the Holocene was similar to today (MAR < 80 mm and annual PET 2000 – 2300 mm). Sensitivity analysis indicates that gypsum accumulation is highly sensitive to MAR and sulfate concentration in rainwater. Synthetic gypsum profiles were calculated using different climate scenarios and then compared to observed gypsum profiles in soils developed on Late Pleistocene surfaces in the same vicinity. Results indicate that simply extending current climate conditions into the Late Pleistocene cannot explain their observed gypsum accumulation; the most plausible climate scenarios for these soils must include increased rainfall to 1.5–2.0 times today's and sulfate concentration in rainwater (2.0–2.5 times than today) to successfully reconstruct the observed accumulated gypsum in mature soil profiles.

<sup>2</sup> National Academy of Sciences of Ukraine, National Museum of Natural History, Kyiv, UKRAINE

<sup>3</sup> National Academy of Sciences of Ukraine, Institute of Geological Sciences, Kyiv, UKRAINE

<sup>4</sup> Taras Shevchenko National University of Kyiv, Kyiv, UKRAINE

Our study investigates the Pleistocene stratigraphy of the Dnieper Basin by analyzing loess and palaeosols, which reveal climate and landscape changes post-Saalian glaciation. We've distinguished between isolated northern loess patches and extensive southern covers, integrating these findings into regional and broader chronostratigraphic contexts.

The scope of our paleoenvironmental investigation extends from the Middle Pleistocene to the Holocene, with a special emphasis on the critical role of palaeosols. These buried soils, encapsulated within aeolian deposits (notably loess units L2-L1), serve as vital stratigraphic records, enabling us to reconstruct past environmental and climatic transitions with remarkable accuracy.

Through the examination of palaeosols across various stratigraphic levels, particularly S2, S1, and S0, we have unveiled local environmental dynamics that played a significant role in shaping Quaternary events post-Saalian glaciation. Our efforts to map the interplay between landscape alterations and aeolian activity have shed light on the underpinnings of Quaternary sediment formation and distribution across both temporal and spatial dimensions.

Employing methodologies such as granulometry, spectrophotometry, chemical analysis, palaeomagnetism, and luminescence dating, we have gained a holistic insight into the origin and development of palaeosols. Furthermore, the application of palynological data for reconstructing palaeoclimatic conditions has led to a more nuanced understanding of climate fluctuations.

In conclusion, our research underscores the invaluable role of palaeosols as key indicators of paleoenvironmental conditions. Their study not only facilitates the reconstruction of past environmental and climatic shifts but also enhances the precision of dating and stratigraphic correlation within Quaternary sediments. This exploration is instrumental in unraveling the complex environmental dynamics of the Pleistocene era in the Dnieper Basin, offering profound insights into paleoclimatic interpretations.

Research carried out as part of the grant of National Science Centre, Poland as the project no. 2018/31/B/ST10/01507 entitled "Global, regional and local factors determining the palaeoclimatic and palaeoenvironmental record in the Ukrainian loess-soil sequences along the Dnieper River Valley – from the proximal areas to the distal periglacial zone".

**REVISITING THE BIOGENESIS OF OXISOL MANTLES (OXISOLS, FERRALSOLS) OF BRAZIL AND THE TROPICS: AN ALMOST FORGOTTEN CONCEPT, CRUCIAL FOR THE FUTURE OF THE TROPICS.**

C. SCHAEFER

Federal University of Vicosa, Soils Department, Vicosa, BRAZIL

Latosols, laterite soils, ferralsols or oxisols cover approximately 70% of the Brazilian landscape, representing the most extensive planetary cover of deeply weathered soils, and the largest current agricultural frontier, responsible for global food security, in modern technical management adapted to the humid tropics. In this work we revisit the biogenetic model of the origin of these homogeneous and well-structured mantles, pointing out that the success of their conversion into agricultural and pastoral ecosystems using high inputs took advantage of their greatest virtues, precisely provided by long-term biological action, mainly by termites and ants. Understanding the cumulative importance of biogenesis can provide the search for ecologically sustainable alternatives, with inclusive and participatory management by ecosystem engineers, aiming for a more lasting and rational use of these unique soils, exclusive to the tropics, without compromising the countless ecosystem services and the protection of immense biodiversity that they shelter, both above ground and underground.

**HOW ARTIFICIAL INTELLIGENCE COULD CONTRIBUTE TO ASSESS SOIL SECURITY DIMENSIONS AND IMPROVE SOIL CONNECTIVITY FOR ALL STAKEHOLDERS OF A SOCIETY.**

C. BASSET<sup>1</sup>, A. ALBOUY-KISSY<sup>1</sup>, B. ABOUY-KISSY<sup>1</sup>

<sup>1</sup> CNAM, Laboratoire Equipe Sécurité Défense, PARIS, FRANCE

<sup>2</sup> IUT Clermont Auvergne, Institut Pascal CNRS, CLERMONT-FERRAND, FRANCE

Supply chain disruptions, geopolitical tensions and inflation increase the risk of food shortage and food production for industrialized countries. Moreover, global peace and security depends on planetary functioning and global food security which rely on the capacity and condition of soils to deliver functions and services that are sustained by soil microbiome activities. Indigenous Microorganisms (IMO) that compose soil microbiomes are organized in trophic levels and sustain most of the seven functions targeted to be protected in the European Union. Respectively: biomass production, storing nutrients and water, biodiversity and carbon pools, physical & cultural environment for human's activities, source of raw materials and archive of geological and archeological heritage. The need to assess soil security becomes systemic and interdisciplinary because the dimensions capital (related to the value of the functions delivered by soils), connectivity (related to how soil is connected with social aspect) and codification (related to legislate to protect soils) depend on the activities coming from whole stakeholders of a society. Many Artificial Intelligence models are currently developing various types of soil assessments and indicators for research purposes as well to provide services to growers. However, most of those are still financially unaffordable for growers and complex to understand when it comes to interpreting results and making changes to farmers' daily practices (e.g. DNAe test). This presentation is part of an ongoing PhD study and aims to discuss Artificial Intelligence targeting to be accessible for all the stakeholders in order to get a quick reading of soil microbiome as an additional indicator of soil health. The objectives are first to reach out for growers and then developing the connection to soil in order to value and protect it (capital & codification) with decision makers who would have direct access to soil data.

##### SOIL SECURITY ASSESSMENT: ESTIMATING THE CAPACITY OF THE SOIL FUNCTION NUTRIENT CYCLING IN THE HUNTER VALLEY WINE GROWING DISTRICT

S. EVANGELISTA, A. MCBRATNEY, B. MINASNY

The University of Sydney, Sydney, AUSTRALIA

A soil centric approach to evaluating soil functions, soil services and threats to soil is essential to monitor and improve soil security to address anthropogenic forces that exacerbate the global existential challenges. This case study aims to explore methods to quantitatively evaluate the biophysical dimensions (capacity and condition [health]) and investigate the spatial variations of the soil's ability to store and regulate nutrients among contemporary land uses, and reference states (genosols and phenosols) in the Hunter Wine Country Private Irrigation District (HWCPID), NSW, Australia. To achieve this, five predominant pedogenon classes of the area were investigated: Wandin (Red Chromosol), Stanleigh (Brown Chromosol), Tamburlaine (Red Kurosol), Sandalyn (Brown Chromosol) and Marrowbone (Calcarosol). For each pedogenon class, soil samples at 0-10cm and 40-50cm depths of the respective genosol and phenosol were collected and a pragmatic list of soil properties were measured for the soil nutrient cycling x capacity (i.e., the soil function x dimension in scope). The respective utility graphs for soil properties were devised based on expert knowledge and from their estimated utility indicators are identified using principal component analysis. The utility of the indicators were then aggregated into an index to assess the capacity of the soil to cycle nutrients and results mapped across the study area.

##### CONNECTIVITY ASSESSMENT AND REFLECTION EVALUATION (CARE) TOOL FOR SOIL SECURITY

J.C. PACHON MALDONADO<sup>1</sup>, D. FIELD<sup>1</sup>, E. LEONARD<sup>2</sup>, R. HEATH<sup>3</sup>, K. MCROBERT<sup>3</sup>, A. .B. MCBRATNEY<sup>1</sup>

<sup>1</sup> University of Sydney, Sydney, AUSTRALIA

<sup>2</sup> AgriKnowHow, Adelaide, AUSTRALIA

<sup>3</sup> Australian Farm Institute, Sydney, AUSTRALIA

A connection to soil enables land managers to not only recognise the intrinsic value of soil as a provider of planetary services and human wellbeing, but also identify risks to soil security. Indeed connectivity, i.e. the intricate network of interactions between individuals, societal groups, and soils, is one of the five dimensions of Soil Security. Soil connectivity is the least developed dimension in the framework, which is structured on 23 soil functions, services and threats (roles). This study developed an evaluation tool to obtain a quantified baseline of soil connectivity for Australia's agricultural land managers. The evaluation tool measures the connectivity of land managers against the characteristics of knowledge, actions, and attitudes to the five threats and three functions in the framework most aligned with production practices. This measurement tool can be integrated into the framework, while also providing users with a connectivity report based on their answers. Spatial representation and analysis are being obtained by promoting the evaluation until at least three answers are collected from each of the 107 socio-economic representative categories located across the whole of Australia. Early results show that 95% of respondents identified at least one threat to their soils, notably erosion and structural decline, and strong connectivity averaging a connectivity level of 0.84 and a median of 0.88. Level of connectivity in decreasing order was for the roles of erosion, soil water management, soil biodiversity loss, acidification, structural decline, nutrient management, decarbonization, and salinity with levels of connectivity of 0.85, 0.81, 0.79, 0.79, 0.76, 0.74, 0.67, and 0.62 respectively. Texture (loam, clay, sandy) and colour (red, brown, black) were the most frequent descriptors used for their soils, often identifying for both soil surface and subsurface characteristics. Preliminary conclusions of the study show Australian farmers have a high connectivity to their soils and mainly use texture and colour for their description. This work is supported by the Australian Research Council Laureate fellowship (FL210100054).

##### CONTINENTAL MONITORING SOIL PROPERTY CHANGES UNDER HUMAN PRESSURE USING PEDOGENON MAPPING

Q. STYC<sup>1</sup>, M. ROMÁN DOBARCO<sup>2</sup>, H.J. JANG<sup>1</sup>, B. MINASNY<sup>1</sup>, A.B. MCBRATNEY<sup>1</sup>

<sup>1</sup> The University of Sydney, Sydney, AUSTRALIA

<sup>2</sup> Basque Centre for Climate Change (BC3), Leioa, SPAIN

Soil properties are susceptible to changes due to human activities, particularly agricultural management. Traditional methods of monitoring these changes often lack the level of detail needed for comprehensive understanding.

This work uses the innovative approach of pedogenon mapping (Román Dobarco et al., 2021) over Australia, which leverages high-resolution environmental covariates as proxies of soil-forming factors, including relief, parent material, and climate. This method delineates 1370 pedogenons in Australia where soils share similar forming factors. To discern soil changes, we employed the concepts of genosoil and phenosoil. Genosoils represent soils evolving under natural conditions, such as woodlands and native vegetation, while phenosoils depict soils under human-induced pressures, like cropping areas and pastures. By integrating data estimating human activity impacts using the global Human Modification map (Theobald et al., 2020) and the Habitat Condition Assessment System map (Harwood et al., 2016b), we can distinguish between these soil types (genosoil or phenosoil) within a pedogenon (Román Dobarco et al., 2023).

Zonal statistics were computed to highlight differences in soil pH and soil organic carbon from soil profiles observations between genosoils and phenosoils.

Our findings indicate discernible changes in these properties, underscoring the impact of human activities on soil evolution. Pedogenon mapping, combined with the genosoil and phenosoil concept, offers a nuanced and precise tool for monitoring soil property changes due to human pressures. This approach holds promise for future research on and policy-making in sustainable land management.

##### SOIL FOOTPRINT: A SIMPLE INDICATOR TO COMMUNICATE AND QUANTIFY SOIL SECURITY

V GARCÍA-GAMERO, A PEÑUELA, T VANWALLEGHEM

University of Córdoba-Department of Agronomy, Córdoba, SPAIN

Soil erosion is one of the biggest threats to soil security, and therefore to agriculture production. Addressing this challenge requires effective strategies to protect soil resources without compromising crop yields. Currently, to fight soil erosion and to define soil sustainable strategies, there are three main players: scientists, policymakers, and land managers. However, the considerable technical knowledge required to understand the link between soil erosion on food production hinders the communication of the potential benefits of soil sustainability strategies to nontechnical stakeholders, such as farmers and food producers. Moreover, a major player in this fight is still missing, consumers. If there is no connection between soil and society then the soil itself may not be valued and it is less likely to be managed sustainably. In this study, we propose the concept of soil footprint, defined as the ratio of soil loss to crop yield, as a simple way to communicate and quantify the soil capital dimension of soil security. This concept offers the opportunity to communicate the tangible cost of annual soil loss from crop production clearly and concisely and to promote the engagement and participation of society in soil resource conservation. By integrating existing data, we have calculated and ranked the soil footprint of the ten main crops in Spain. We are developing an online soil footprint calculator to facilitate the calculation of the soil footprint from both food production and food consumption. Since the soil footprint is a versatile concept that can be applied at different temporal and spatial scales, we discuss some of its multitude of potential uses.

##### MONITORING THE CONDITION OF FOREST SOILS IN THE BASQUE COUNTRY (SPAIN). AN APPLICATION OF PEDOGENON MAPPING FOR POLICY IMPLEMENTATION.

M ROMAN DOBARCO <sup>1</sup>, A MCBRATNEY <sup>2</sup>, J CURIEL YUSTE <sup>1</sup>, S CORNU <sup>3</sup>

<sup>1</sup> Basque Centre for Climate Change BC3, Terrestrial Ecosystems, Leioa, SPAIN

<sup>2</sup> The University of Sydney, Sydney Institute of Agriculture & School of Life and Environmental Sciences, Sydney, AUSTRALIA

<sup>3</sup> CEREGE, Aix-Marseille University, CNRS, IRD, Coll de France, INRAE, Aix-en-Provence, FRANCE

The assessment of soil condition needs to consider the context of soil-forming factors for identifying indicators' reference values for specific different soil types. The European Commission proposal for a Soil Monitoring Law suggests establishing soil districts for monitoring and assessing healthy soil condition. Soil districts would be established considering administrative boundaries but also the homogeneity in soil type, climate, environmental zone and land use. Pedogenons are a possible way of delineating and characterising soil districts. In the Basque Country forests have been subjected to enormous pressure, especially since the beginning of the 20th century, hence it is important to obtain information on how intensive practices may have affected soil condition. The aims of this study are: 1) to apply pedogenon mapping for the delineation of potential soil districts in the Basque Country, 2) to assess changes in soil condition indicators in forest soils between 2001 and 2021 via the genosoil/phenosoil concept of pedogenons, and 3) to identify reference or target values of soil indicators for each soil district. Pedogenons are classes defined applying unsupervised classification to a set of quantitative state variables that represent the soil-forming factors. The hypothesis is that classes with homogeneous conditions in soil-forming factors would undergo similar pedogenesis and result in soils with similar capacity for performing soil functions and services and response to management. Within each pedogenon we might find genosoil and phenosoil subclasses. Genosoils result from natural pedogenesis (or minimal anthropogenic pressure) while phenosoils are variants from the genosoil due to land use history and management. Soil data from Basonet, the permanent network for forest monitoring in the Basque Country, was used to assess changes in soil condition by soil district. The set of soil condition indicators were bulk density, soil organic carbon to clay ratio, extractable phosphorus, total nitrogen, pH, and electric conductivity. Time series of satellite imagery and historical orthophotos were used to connect the intensity of forest management to soil condition.

<sup>3</sup> School of Geosciences, University of Louisiana at Lafayette, Louisiana, USA

<sup>4</sup> Lorraine university, Nancy, FRANCE

<sup>5</sup> University of Applied Science of Western Switzerland Hepia, Geneva, SWITZERLAND

Phytotechnology also referred to as phytoremediation is a non-destructive technology for the remediation of soils that uses plant species to extract, contain, fix, or degrade and decompose inorganic or organic pollutants. It aims to control pollution transfer in environmental compartments and to limit associated risks while integrating site enhancement objectives.

The success of phytotechnologies can be hindered by poor soil quality, deep soil contaminants, and the difficulty of implementing a plant cover. Additionally, they require a long-term application and induce regular management costs. Constructed soils are engineered mixtures of organic and mineral materials including waste or modified soil horizons, combined with biotic selections. Constructed soils have great potential for surpassing the majority of phytotechnologies limits and improving their outcome.

The purpose of this review is to explore the efficacy of combining constructed soils and phytotechnologies while considering the type of contaminant (organic or inorganic), its concentration, speciation, and spatial distribution. The review will also explore the most appropriate biotic and abiotic conditions, and derive considerations for amendments selection, to improve the effectiveness of contaminated site management.

The use of constructed soils is a viable way to restore crucial ecosystem services, reduce costs, adapt to climate change, and enhance waste management by utilizing locally available waste materials. Constructing soils is a promising approach to facilitate the management of contamination sites while ensuring better climate mitigation.

##### COMMUNICATING SOIL HEALTH ASSESSMENT TO ON-FARM AND OFF-FARM STAKEHOLDERS

C. MORGAN, N. LOOKER, D. BAGNALL, M. CLOUTIER, D. LIPTZIN

Soil Health Institute, Morrisville, USA

Collecting effective, interpretable soil health measurements across soil types and management practices is an essential step toward helping land managers set and achieve soil health goals. The Soil Health Institute and its partners have endeavored to benchmark soil health potential and improvements that producers have achieved across North America. The Institute is collecting data using the minimum suite of recommended measurements, including organic carbon concentration, wet aggregate stability, and carbon mineralization potential, along with soil texture. These indicators are measured across an a priori map of soil groups identified to have similar soil health potential, and across regionally representative management categories, which include, baseline crop production systems, soil health management systems, and reference systems that express the soil health principles such as maximizing living roots and minimizing disturbance. Upon analysis and synthesis of the data, learning how to communicate the results to farmers, crop consultants, retailers, commodity groups, and buyers interested in paying premiums, is the challenge. We reflect on learnings regarding the connectivity dimension of soil security and how we are communicating the results of our soil health benchmarking work. We summarize our multipronged communication strategy for putting soil health benchmarks in the hands of producers, crop consultants, retailers, and buyers and share feedback that we have received regarding the efficacy of our approach.

##### THE EFFECT OF BACILLUS MEGATERIUM VAR. PHOSPHATICUM INOCULUM ON SOIL ENZYMATIC ACTIVITY AND YIELD IN NO-TILLAGE MAIZE CROP

A. URSU <sup>1</sup>, G. BIREESCU <sup>2</sup>, S.S. CAKPO <sup>1</sup>, G.D. MIHU <sup>1</sup>, D. TOPA <sup>1</sup>, G. JITAREANU <sup>1</sup>

<sup>1</sup> University of Life Sciences - Soil Management, Iasi, ROMANIA

<sup>2</sup> Institute of Biological Research, Iasi, ROMANIA

In the current environmental context, conservation agriculture and eco-friendly alternatives to conventional practices play an important role, but these require soil and plant assessments. Enzymatic activity is essential in transforming soil organic matter and determining nutrient dynamics being a key component of the soil health. This research investigated the effect of applying *Bacillus megaterium* var. *phosphaticum* bacteria on catalase (CAT) and dehydrogenase (DHA) activity, plant biometric parameters (cob length - CL, grain weight /cob - GW and cob biomass - CB) as well as maize yield (*Zea mays* L.) in no-tillage system (NT). The study was conducted in 2023 in Northeastern Romania on a non-irrigated cambic chernozem soil with clay-loam texture and slightly acid reaction. For fertilization were used: NPK (20% N, 10% P<sub>2</sub>O<sub>5</sub>, 5% K<sub>2</sub>O); Ecofert (Bacillus megaterium var. phosphaticum) and Corona N (21% N). Experimental plots were fertilized with the following formulations: T0 - NPK (control); T1 - NPK + 100% Ecofert; T2 - NPK + 75% Ecofert + Corona N; T3 - NPK + 100% Ecofert + Corona N; T4 - NPK + 125% Ecofert + Corona N. Results on catalase and dehydrogenase activity showed high values in Ecofert treated variants. Significant differences ( $p < 0.05$ ) from the control were reported at T1, T2, T3. Cob length, grain weight /cob and cob biomass were higher in all Ecofert treatments. Grain yield was significantly different, being 63% higher in T3 and 68% in T4 compared to the control. Data collected so far reveals a positive response of soil microorganisms, through enzymatic activity dynamics, to the recommended dose of Ecofert associated with foliar fertilizer. The beneficial effect was also reflected in the yield parameters of the no-tillage maize crop.

Soil microbial communities influence plant growth and defenses, including indirect defenses affecting the attraction of natural enemies. Microbial inoculants, such as those based on arbuscular mycorrhizal fungi (AMF), could potentially boost plant defenses, but their impact in natural settings is not well understood. Our study investigates the potential of AMF, specifically *Rhizoglyphus irregularis*, as a soil bioinoculant to enhance plant defenses. We examined its impact on the roots microbiota and subsequent effects on tomato plants, both wild (*Solanum pimpinellifolium*, var. LA1589) and commercial (*Solanum lycopersicum*, var. Monita), when attacked by the pest *Spodoptera exigua* (Hübner). We also assessed its influence on the attraction of the pest's natural enemy, *Chrysoperla carnea* (Steph.).

In our study, we found that pest attack altered the natural volatile emissions in both commercial and wild tomato species. Notably, in the case of wild tomatoes, the effects of the pest attack and the inoculation of *R. irregularis* appeared to interact synergistically on volatiles profile. Furthermore, the presence of mycorrhiza increased the attractiveness of the pest predator to attacked plants in both types of tomatoes, compared to plants that were attacked but not inoculated with *R. irregularis*. However, it remains unclear whether this increased attractiveness is due solely to changes in volatile blends or if additional effects of mycorrhiza on the root microbiome contribute to the observed phenotype. Our results support that shifts in the metabolically active fungal communities in the roots also contribute to this phenomenon.

Maize is one of the oldest crops in the world and has gained an important role in global agri-food systems. In addition to the use of organic fertilizers, microbiome-based solutions have been suggested as a safe and eco-friendly solution for reducing the application of chemical fertilizers to a great extent. The main objective of the present work is to assess the impact of synthetic microbial consortia developed within the SIMBA project, the fertilization regimes and maize growth stages on plant growth, and on taxonomic and functional rhizosphere microbiome under temperate climate conditions. The effect of microbial consortia inoculation on the non-target rhizosphere soil microbiome was investigated by a coupled approach based on 16S rRNA gene sequencing and shotgun metagenomic (WGS) sequencing and bioinformatic analysis. The application of MC exerted a positive effect on plant growth especially at lower fertilization levels in 2020 while significant increases in grain yield (+10%) were observed in 2021 only when MC\_C was applied in combination with Arbuscular Mycorrhizal Fungi. MC application did not significantly affect species diversity and richness of the native rhizosphere microbial communities, as well as their functional properties, suggesting the resilience of rhizosphere microbial communities in response to MC. In contrast, higher fertilization level and plant growth stages affected rhizosphere bacterial community. Finally, WGS metagenome sequencing revealed slightly significant differences in rhizosphere microbiome only between low and high fertilization levels and a significantly higher relative abundance of reads assigned to the SEED category "Nitrogen fixation" at low fertilization level (p-value of 0.03), suggesting that fertilization alter the pool of genes assigned to nitrogen fixation. Overall, our results suggest that multifunctional MC may be effectively exploited as biofertilizer in sustainable maize cultivation without altering the biodiversity or the resident microbiota, thus avoiding risks of long-term impacts on natural biodiversity. Funded from the European Union's Horizon 2020 research and innovation programme under grant agreement No. 818431 (SIMBA), EJP SOIL and SOIL HUB projects.

##### THE USE OF MICROBIAL BASED INOCULANTS FOR ENHANCING THE TOLERANCE OF TOMATO PLANTS TO DIFFERENT ABIOTIC STRESS CONDITIONS: PRELIMINARY RESULTS

A ESPOSITO<sup>1</sup>, F VITALI<sup>1</sup>, V SCALA<sup>2</sup>, L CANFORA<sup>3</sup>, S MOCALI<sup>1</sup>

<sup>1</sup> Council for Agricultural Research and Economics (CREA), Research Centre for Agriculture and Environment, Florence, ITALY

<sup>2</sup> Council for Agricultural Research and Economics (CREA), Research Centre for Plant Protection and Certification, Rome, ITALY

The microbial inoculants are gaining interest in sustainable agriculture as a promising approach to minimize the decline in crop growth and productivity under continuous biotic and abiotic stresses. However, although the results of applying microbial-based products in controlled conditions are encouraging, their efficiencies under field condition remain variable. A better understanding of the mechanisms driving the interactions between plant, soil and associated microbes in mediating stress response is a crucial point for the translation to croplands and in higher productivity systems. Several secondary metabolites, such as oxylipins, produced by plants in response to stress conditions, play a significant role in enhancing stress tolerance. Although these metabolites have been extensively investigated in relation to biotic stress, their role in plant responses to abiotic stress conditions is less studied.

Here, we report preliminary finding from a trial in which tomato plants, grown in greenhouse conditions, were exposed to three different salinity concentration for 21 days. This preliminary work aims to determine i) the threshold levels of stress conditions and the timing that affects the growth of plants through analysis of qualitative and quantitative oxylipins and ii) the rhizosphere microbiome community changes at different timepoints following initial stress applications.

The data obtained revealed a significant difference in microbiome biodiversity between control and saline stressed conditions. The diversity of plant-associated microbiome in stress condition was significantly lower at 7 and 14 days following salinization and it recovered at the end of trial. Furthermore, the response to stress resulted in shift in community structures between experimental conditions, that was relevant at 7, 14 and 21 days after stress application. At the same timepoints, a significant difference in the type and quantity of oxylipins from stressed plant was observed.

Interestingly, the role of those metabolites in salinity stress is almost unexplored, and the comparison of oxylipins and soil microbiome will allow a thorough study of the interaction of these elements in determining tolerance to environmental stresses.

Polyhalite is a mineral used directly as a source of potassic fertiliser for different crops. Polyhalite is naturally occurring mineral and supplies calcium magnesium and sulphur in addition to potassium. An experiment was conducted at farmer's land, Arachalur, Erode district, Tamil Nadu. The soils of Arachalur village were classified under the textural class sandy loam. An initial soil sample had the pH, electrical conductivity and cation exchange capacity of 6.80, 0.06 ds m<sup>-1</sup>, 10 C mol (p+) kg<sup>-1</sup>, respectively. The organic carbon content of the soil was 3 g kg<sup>-1</sup>. Available nitrogen, available phosphorus (Olsen) and available potassium of the soil were 270, 10 and 100 kg ha<sup>-1</sup>, respectively. The field experiment was laid out in randomised block design consisting of ten treatments and replicated thrice. The treatments included were T1-Control, T2- N,P, K=0, T3-N, P, K= 100%( RD) (181 kg ha<sup>-1</sup> MOP), T4-N, P, K= 50% (90 kg ha<sup>-1</sup> MOP), T5-N, P, K= 50% (Polyhalite 380 kg ha<sup>-1</sup>), T6-N, P, K= 100% (Polyhalite) (750 kg ha<sup>-1</sup> Polyhalite), T7-N, P, K= 100% (50 % as MOP + 50% as Polyhalite) (90 kg ha<sup>-1</sup> MOP + 380 kg ha<sup>-1</sup> Polyhalite), T8-N, P, K =150% ( MOP ) (250 kg ha<sup>-1</sup> MOP), T9-N, P, K = 150% (100 % MOP + 50 % polyhalite as K<sub>2</sub>O) (180 Kg ha<sup>-1</sup> MOP +380 kg ha<sup>-1</sup> Polyhalite), T10-N, P, K = 150% (50% MOP +100 % K<sub>2</sub>O as Polyhalite)(90 kg MOP + 750 kg ha<sup>-1</sup> Polyhalite). The treatment (T10) recorded the maximum SPAD meter readings of 22.5, 31.3 and 44.8 at 90, 120 and 210 DAT respectively. The maximum fresh yield (33 t ha<sup>-1</sup>) and cured yield (6.67 t ha<sup>-1</sup>) were also recorded in treatment T10. Thus the study was helpful to farmers for yield maximisation of turmeric through Polyhalite as potassic fertiliser.

**INTERACTION OF RESIDUAL NICKEL AND ZINC APPLICATION BENEFICIAL FOR PHYSIOLOGICAL AND NUTRITIONAL QUALITY OF COWPEA AND BIOCHEMICAL PROPERTIES OF SOIL UNDER VERTISOL**

S K SINGH, S GOSWAMY

#### **Affiliations**

Department of Soil Science and Agricultural Chemistry, Institute of Agricultural Sciences, Banaras Hindu University,, VARANASI, INDIA

Nickel (Ni) and zinc (Zn) have been considered as an essential nutrient for plant growth and development. The importance of Ni in plant nutrition was first noticed as Ni deficiency symptoms of “mouse ear” found in the young leaves of pecan trees (*Carya illinoensis* K.). Soil application of Ni has low efficiency and expected to produce enough residual effect to cater the need of the next crop in the sequence. A pot experiment was conducted on the soil of previous season pot study, where in the Ni and Zn was applied with recommended dose of fertilizers (RDF). This study with cowpea as test crop was conducted on residual level of Ni in soil along with application of recommended dose of fertilizers (RDF) and Zn. The result showed significant increase in plant height, greenness index, number of branches, number of pods plant<sup>-1</sup>, number of seed pod<sup>-1</sup>, stover yield, seed yield and weight of 100 seed of cowpea. All these attributes were highest at 10 mg Ni kg<sup>-1</sup> applied in the previous crop along with Zn at the rate 10 mg kg<sup>-1</sup> in the current experiment (T10). The concentration of iron (Fe), manganese (Mn) and Zn in grain and stover significantly increased up to 10 mg kg<sup>-1</sup> residual Ni (T10) and beyond this a reduction in concentration was observed. Behaviour of these elements with respect to uptake in both grain and stover was similar as that of their concentration. The urease activity and available N content in soil significantly increased with the increase in residual Ni content. The utilization of residual Ni in soil applied in previous crop could be an effective strategy for sustainable management of Ni application in Ni-deficient soil. This may lead to better N fixation and provided higher yield of cowpea.

Integrated crop-livestock-forest systems (ICLFs) are a sustainable strategy for land use intensification, integrating annual crops, trees, and livestock in the same area and season. Climate, soil, crop, and animal interactions in ICLFs are complex and synergistic or competitive, depending on the arrangements over time and space. Therefore, digital tools like precision agriculture (PA) can be decisive for collecting, processing, and analyzing temporal and spatial data, combining them with other information to support management decisions and considering the estimated variability. Furthermore, it also contributes to improving the management and use efficiency of resources and inputs, with minimum environmental damage risks. Lime and fertilizer are critical factors for agriculture intensification in the Brazilian tropical acid-low-fertility soils. Knowing the spatial variability of soil properties by technologies such as GPS, sensors, GIS, advanced software, and variable rate technology (VRT) equipment is essential for the rational use of inputs, as in integrated nutrient management (INM). This research aimed to evaluate, monitor, and manage the spatiotemporal variability of soil properties, liming, and fertilizer requirements. A field study was conducted in a 30-ha area in São Carlos, SP, Brazil. An INM strategy has been adopted based on soil tests to determine soil nutrient availability, deficiency, and soil fertility management with VRT. From 2014 until now, yearly soil samples were collected at 0-0.2 m depth, and each sample represented a 0.5-ha paddock. Spatial variability soil properties and site-specific liming and fertilizer needs were modeled by inverse distance weighting technique. Liming and fertilization were carried out yearly based on interpretations and prescription maps. Results showed that generating thematic maps was essential to define the rational use of inputs by the spatial analysis of liming and fertilization requirements. Variable rate lime and phosphate fertilizer application technology leads to soil buildup and greater homogeneity of soil chemical attributes. INM practice can be guided by soil nutrient prescription maps and provide a history of land, issue use, and soil conditions.

Soil water fluxes influences inorganic nitrogen (N) because their transport, transformation, storage and potential losses from an agroecosystem are determined by the hydraulic gradients that occur in the soil, as being a result of drying and wetting cycles (D-W cycles). The objective of this research is to evaluate the temporal availability of N physically stored in the range of matric potentials corresponding to pore diameters between 0.2 and 50  $\mu\text{m}$ , in five volcanic ash soils under permanent grassland during continuous D-W cycles. Undisturbed soil samples were collected at two depths: 0-10 and 10-20 cm ( $n = 5$ ), using stainless steel cylinders (610  $\text{cm}^3$ , with  $\varnothing=8.8$  cm and  $h=10$  cm). Soil samples were pre-incubated for 24 hours added 5 ml solution with  $\text{K}^{15}\text{NO}_3$  (98 atom % $^{15}\text{N}$ ). The labeled solution was added evenly over the soil surface. All soil samples (cores) were subjected to five D-W cycles. Dry conditions were determined when the core is equilibrated to 100 kPa. Wetting conditions were performed by applying distilled water to the top of the soil cores and leaving the soil to equilibrate until the soil water content reaches - 6 kPa of matric potential. The water that was drained for ~10 days until reaching an equilibrium equivalent to ~ 100 kPa (50% of PAWC according to water retention curve) was collected in a plastic bottle from the pressure chamber and stored cold until analysis of isotopic ratios. The physical soils' capacity to store available nutrients in time and space (mineral N movement in depth is approximately 1 cm per day in volcanic soils) forms part of a new line of study that includes the dynamic nature of soil, which depends on the hydraulic properties of the soil, the functionality of the pore system, and the spatial arrangement of its particles and aggregates. Therefore, the "physical soil condition" plays a fundamental role in the sustainable management of soil fertility.

##### BASICS OF BALANCED USE OF ALBIC PANTOSTAGNIC LUVISOL

Y OLIFIR, A HABRYEL, T PARTYKA, O HAVRYSHKO, N KOZAK

Institute of Agriculture of Carpathian Region of NA AS of Ukraine, Department of Agrochemistry and Soil Science, Obroshyne, &#1059;&#1050;&#1056;&#1040;&#1031;&#1053;&#1040;

In modern conditions of agro-industrial production, fertility management involves constant correction of reclamation and technological measures in accordance with climate change and the course of soil processes.

Among the gas flows entering the atmosphere, CO<sub>2</sub> emission from the soil surface is one of the most powerful. Even slight disturbances of soil respiration on a global scale can lead to serious changes in the concentration of this gas in the atmosphere. Spontaneous processes of transformational development of soils and the formation of their fertility should be contrasted with a scientifically based system of management of these processes. Management decisions should be aimed at preventing soil degradation, gradually cultivating and reproducing their fertility.

Research conducted under the conditions of a long-term stationary experiment on acidic Albic Pantostagnic Luvisol showed that periodic application before each of the following four-field rotations of 2.5 t ha<sup>-1</sup> of lime, calculated according to the pH-buffering model, when using an organo-mineral fertilization system with application of 10 t ha<sup>-1</sup> of crop rotation area of manure + N65P68K68 optimizes the carbon regime of the soil to the greatest extent. Losses of Carbon dioxide from the soil during the growing season of crops are reduced by 1.5-2.0 times compared to the identical fertilization system with the background of lime application 6.0 t ha<sup>-1</sup> by the hydrolytic acidity and control without fertilizers. At the same time, the introduction of lime calculated according to the pH-buffering model ensures the rational use of fertilizers and meliorant. In the soil, the acidity, the content of mobile aluminum compounds decreases, and the content of nutrients increases.

Thus, the introduction of lime according to the pH-buffering model on acidic Albic Pantostagnic Luvisol soils slows down the processes of increasing the concentration of CO<sub>2</sub> in the atmosphere, minimizes the manifestations of global warming, thereby laying the foundations for the protection of acidic soils from decreasing fertility and general degradation.

##### MANAGING NITROGEN FOR GLOBAL SUSTAINABILITY

B GU

Zhejiang University, Hangzhou, CHINA

##### Body

Nitrogen plays a pivotal role in both positively impacting global sustainability, particularly in agriculture, and negatively contributing to environmental issues. Striking a balance between maximizing its benefits and minimizing its adverse effects poses a significant global challenge, especially in the context of ongoing global changes. In this study, we undertake a comprehensive analysis of nitrogen management, focusing on achieving global sustainability. This approach aligns with the United Nations' goal of halving nitrogen waste to attain the Sustainable Development Goals (SDGs). Our findings reveal that various socioeconomic factors, including farm size, the decoupling of crop and livestock, rural aging, urbanization, and livestock species, exert substantial influence on global nitrogen utilization and loss. Moreover, global climate change threatens the sustainable utilization of nitrogen for food production and introduces significant spatial disparities in global nitrogen cycle. Consequently, proactive adaptation measures will be essential in addressing these challenges in the future.

To enhance nitrogen use efficiency while reducing nitrogen pollution, we propose the establishment of a nitrogen credit system, serving as a central platform that integrates best management practices, socioeconomic adjustments, and climate change considerations. This integrated approach has the potential to enhance overall progress toward global SDGs by up to 20%. The associated total social benefits could amount to an impressive US\$1,300 billion, considering improvements in human and ecosystem health and contributions to climate change mitigation. Importantly, implementing such a cost-effective nitrogen waste reduction strategy would require an investment of only US\$300 billion. Our findings offer crucial insights for policymakers, underscoring the urgency of implementing cost-effective strategies to reduce nitrogen waste and promote global sustainable development.

<sup>3</sup> Minnesota Department of Health, St Paul, USA

<sup>4</sup> Deseret Farms of California, Chico, USA

<sup>5</sup> USDA-NRCS, Pullman, USA

Meeting the increasing demands for agricultural products needing large N inputs while mitigating environmental impact in the context of climate change converge in a difficult conundrum to solve. While N best management practices (N-BMPs) for corn have been researched intensively for agronomic outcomes, the same emphasis on environmental outcomes is lacking. Further, studies of N-BMPs that integrate various N loss pathways with agronomic outcomes are chronically insufficient to determine whether N-BMPs to improve corn production are concomitantly sufficient to mitigate N loss. A number of studies located on a poorly-drained fine-textured soil with subsurface drainage, and in a well-drained coarse-textured soil in Minnesota, USA were started in 2014 to measure corn grain yield, total crop N uptake, residual soil N after harvest and season-long NO<sub>3</sub> leaching and NH<sub>3</sub> and N<sub>2</sub>O emissions. Enhanced practices combining N source, rate, time, and application method were evaluated against traditional practices. The coarse-textured site also had no cover-crop, winter rye cover-crop, and kura clover living-mulch. Generally, crop N uptake and grain yield showed a quadratic-plateau response to N rate. Though environmental N losses often increased with increasing N rate, the losses were small and grain loss large in the quadratic portion of the curve. Conversely, N rates above the economic-optimum resulted in less profitability and substantial N loss. Using polymer-coated urea (an enhanced efficiency source), often reduced N loss and maintained productivity and profitability. Splitting the N application in-season had agronomic and environmental advantages in the coarse-textured soil, but had only agronomic advantage in the fine-textured soil. Because of poor growth, the rye cover crop had no effect on agronomic or environmental outcomes, but kura clover substantially reduced NO<sub>3</sub> leaching, slightly increased NH<sub>3</sub> losses, but reduced grain yield substantially, diminishing potential adoption by farmers. While the dual goal of improved corn production and environmental protection are attainable, precipitation after fertilization largely influenced N loss and diminished the otherwise attainable benefits of refining N management practices.

<sup>6</sup> Zhejiang University, Zhejiang Provincial Key Laboratory of Organic Pollution Process and Control, Hangzhou, CHINA

To address phosphorus (P) scarcity and reduce dependence on phosphate rock resources, particularly in soils with high P fixation capacity, it is crucial to mobilize plant-unavailable soil P and residual P for crop demand. Low molecular weight organic acids and their salts (LMWOAs) are recognized as effective methods for soil and residual P mobilization. However, previous research mainly focused on P extraction using LMWOAs solutions and traditional adsorption and desorption, with limited in situ studies on LMWOAs application to soil. Furthermore, the co-application of LMWOAs with inorganic and organic P and their sustainable ability to enhance soil P availability have been insufficiently explored. We selected acidic red soil, which has high P fixation capacity and low available P and compared with a calcareous alluvial soil (rice-growing soil) in China and examined the P availability using XANES and <sup>31</sup>P-NMR for characterizing organic and inorganic P functional groups as well as the latest international DGT-DET-3D DIFS model coupling technology. These technologies assisted us in quantifying the degradation, diffusion, adsorption and desorption processes of the non-labile, labile and available P as well as that of LMWOAs. In addition, we analysed microbial community structure, key enzyme activities involved in P, carbon and nitrogen cycling to investigate the abiotic and biological mechanisms of LMWOAs and their synergistic effects in mobilization of soil P to increase available P. It was found that small organic acids significantly enhance available phosphorus in acidic red soil, with 50M citric acid increasing DGT-P by 17 times and soil pore water phosphorus by over 600 times, while its impact on a calcareous alluvial soil was comparatively minimal. This difference was attributed to significant non-biological and biological effects of the added LMWOAs on the former, but not significant effects on the latter. Application of these findings will save the increasingly scarce phosphate rock resources, as well as increase agricultural production from the applied phosphorus fertilizer, especially in the acidic red soil.

##### TO THE MOON AND MARS! RECYCLING ORGANICS FROM AEROPONIC PLANT WASTES AND SOURCING MICROORGANISMS FOR OFF-WORLD FARMING

H COKER, J HOWE

Texas A&M University - Department of Soil and Crop Sciences, College Station, USA

##### Body

On the moon and Mars, low bioavailability of several plant essential nutrients and abundant toxic oxidants and salts in unaltered surface minerals will impede crop productivity. Generating a steady food supply is essential for the success of human settlement and will require sustainable and recycled nutrient sources. A soilless cultivation practice – aeroponics – has received attention for versatility and success in low gravity and space flight environments. In aeroponics, organic compounds exuded by root systems are recirculated that could be utilized to fortify organic matter in extraterrestrial soils. An aeroponic system that enriches lunar and Martian soils is proposed. Through continual inundation of organically rich rhizodeposition products and the full suite of plant essential nutrients, it is hypothesized that fertility can be conferred to Martian regolith to support the growth of subsequent soil-based crops. Additionally, the selection and introduction of beneficial plant microorganisms will be essential for plant productivity, especially those capable of reducing harmful perchlorate salts. An experimental study of several microorganisms with perchlorate reducing activity assesses their ability to improve lunar and Martian soils. A recommended approach to terraforming lunar and Martian soils for sustainable nutrient management is provided.

**SUPPRESSION OF NITRIFICATION AND N<sub>2</sub>O EMISSION BY PHENOLIC ACID BNIS IS LINKED TO AMMONIA OXIDIZING BACTERIA, NITRITE-OXIDIZING NITROSPIRA AND NOSZ-N<sub>2</sub>O REDUCER POPULATIONS IN AN ACIDIC SOIL**

W SHI<sup>1</sup>, Y LU<sup>1</sup>, Y HUA<sup>1</sup>, H KRONZUCKER<sup>2</sup>

<sup>1</sup> Institute of Soil Science, Chinese Academy of Sciences, Najing, CHINA

<sup>2</sup> The University of Melbourne, School of BioSciences, Melbourne, AUSTRALIA

Plant derived biological nitrification inhibitors (BNIs) are a new strategy to reduce soil nitrogen loss and improve nitrogen utilization efficiency. Several BNIs have been found in root exudates and extracts of different plants. However, the impact of different BNIs on soil nitrification and N<sub>2</sub>O emissions is still unclear. The purpose of this study is to evaluate the effects and biological mechanisms of phenolic acid BNIs and fatty acid BNIs on nitrification and N<sub>2</sub>O emission in an acidic soil. Three typical phenolic acid BNIs have a 40% inhibitory effect on nitrification in acidic soil, while fatty acid BNIs have no significant effect. Phenolic acid BNIs significantly inhibited the amoA gene abundance of ammonia-oxidizing bacteria (AOB) and nxrB gene abundance of nitrite-oxidizing bacteria (NOB) and altered the community structure. The results of community composition showed that phenolic acid BNIs reduced the abundance of Nitrosospira cluster 3a.1 and Nitrosospira bockiana. Similarly, phenolic acid BNIs also have a significant inhibitory effect on N<sub>2</sub>O emissions through impeding both AOA and AOB, and promoting nosZ genes. Overall, our results support the potential for the use of phenolic acid BNIs in mitigating N<sub>2</sub>O emissions and enhancing N utilization in acidic soils.

**BIOSTIMULANTS DECREASED NITROGEN LEACHING AND NH<sub>3</sub> VOLATILIZATION BUT INCREASED N<sub>2</sub>O EMISSION FROM PLASTIC-SHED GREENHOUSE VEGETABLE SOIL**

J MIN

Institute of Soil science, Chinese Academy of Science, Nanjing, CHINA

Biostimulant application is an effective strategy to enhance soil fertility and plant growth. However, its comprehensive impacts on nitrogen (N) uptake and reactive N (Nr) losses via leaching, ammonia (NH<sub>3</sub>) volatilization, and nitrous oxide (N<sub>2</sub>O) emission from plastic-shed greenhouse vegetable system are still little known. Therefore, a field experiment was conducted with cauliflower tomato growth rotation receiving three biostimulants, i.e., humic acid (HA), algae extract (AE), and chitosan (CT), as well as a control without stimulant. The cumulative Nr losses over the cauliflower-tomato growth cycle via leaching, NH<sub>3</sub> volatilization, and N<sub>2</sub>O emission were 104–175 kg N ha<sup>-1</sup>, 2.32–3.85 kg N ha<sup>-1</sup>, and 0.70–0.85 kg N ha<sup>-1</sup>, respectively. Biostimulant application significantly ( $P < 0.05$ ) retarded the total N leaching by 17–44% in tomato season, while suppressed the NH<sub>3</sub> volatilization by 18–38% in cauliflower season. Overall, AE showed the best inhibition efficiency on Nr losses by significantly ( $P < 0.05$ ) decreasing total N leaching and NH<sub>3</sub> volatilization by 36–44% and 38–52% in both vegetable seasons, compare to the control. However, all three biostimulants stimulated the N<sub>2</sub>O emission under both vegetable cycles. Interestingly, all biostimulant-added treatments promote the cauliflower and tomato yield, particularly following the HA and AE amendments, which bring local farmers approximately 4,384–10,035 yuan RMB ha<sup>-1</sup> more income. Enhanced yield under biostimulant treatments was due to higher N uptake capacity and enhanced root morphology. In summary, biostimulants have a contrasting influence on three major Nr lost pathways in greenhouse vegetable production. We recommend that AE is the most optimal biostimulant as it increases vegetable yield and decreases total N leaching and NH<sub>3</sub> volatilization while not dramatically increase the N<sub>2</sub>O emission.

##### SOIL METAGENOME INSIGHTS INTO THE PHOSPHORUS CYCLE OF A MAIZE AGROECOSYSTEM FERTILIZED WITH STRUVITE AND SLUDGE

M B BARQUERO MARTÍNEZ, C GARCÍA DÍAZ, J L MORENO, R LÓPEZ MONDÉJAR, F BASTIDA

CEBAS-CSIC, Soil and Organic Waste Enzymology and Bioremediation Group., Murcia, SPAIN

The recycling of residues, such as sludges and struvites, as phosphorus-rich fertilizers, emerges as a promising strategy to address the scarcity of conventional fertilizers while sustaining soil health and its microbiome. The application of bioinformatics techniques has proven indispensable for analyzing microbial communities in environments like soil. In a field experiment conducted in a maize crop in Murcia, Spain, we assessed various fertilization types (conventional, struvite, sludge, and organo-mineral) and their impact on key genes related to the phosphorus cycle in soil microbial communities across different phenological stages.

Results revealed substantial changes in the abundance of phosphorus cycle-related genes based on fertilizer type and phenological stage. The bacterial community was dominated by Actinobacteria, Proteobacteria, Acidobacteria, and Chloroflexi, with a notable increase in *Conexibacter* and *Nocardioides* during flowering in sludge and struvite treatments. The archaeal community was dominated by Thaumarchaeota, Euryarchaeota, and Crenarchaeota, with an increase in *Aeropyrum* and *Halorubrum* during flowering. At the functional level, genes such as *phnG*, *phnJ*, and *phnL* exhibited significant variation among treatments and stages, emphasizing the importance of nutrient-microbiota interactions.

In summary, bioinformatics and metagenomics serve as powerful tools for unraveling microbial functionality in enhancing phosphorus availability in the soil. The choice of fertilizer and phenological stage impacts microbial activity and nutrient availability, underscoring the necessity of considering these interactions to optimize soil fertilization for agricultural sustainability.

##### CHANGES IN PADDY SOIL FERTILITY IN TROPICAL ASIA UNDER THE GREEN REVOLUTION DURING THE LAST HALF CENTURY – IMPLICATIONS FOR THE FUTURE

J YANAI<sup>1</sup>, S TANAKA<sup>2</sup>, S ABE<sup>3</sup>, A NAKAO<sup>1</sup>

<sup>1</sup> Kyoto Prefectural University, Kyoto, JAPAN

<sup>2</sup> Kochi University, Nankoku, JAPAN

<sup>3</sup> Kindai University, Arida, JAPAN

Over 50 years of the Green Revolution since the 1960s, the global population has increased by 2.5 times, cereal production by 3.3 times, and the use of N, P and K fertilizers by 9.4, 4.2, and 4.3 times, respectively. Information is still limited on the influence of these impacts on the fertility status of paddy soils. We therefore investigated the influence of the Green Revolution on 142 paddy soils in three tropical Asian countries, i.e., Thailand, the Philippines and Malaysia, by repeated soil sampling in the 1960s and 2010s at or near the same locations. We revealed that the availability indices of three macronutrients, i.e., available P, total N, and exchangeable K, showed 843% ( $p < 0.01$ ), 112%, and 101% increase on average, respectively, whereas total C showed 9% decline. Comprehensive investigation of overall fertility status by factor analysis using 11 soil parameters suggested that only the factor scores associated with “available P status” increased drastically in all the three countries ( $p < 0.01$ ) (Fig. c) whereas those associated with “organic matter and N contents” and “inherent potentiality” did not exhibit any consistent changes (Fig. a, b). In conclusion, intensive soil/fertilizer management systems under the Green Revolution have successfully improved the nutrient status, especially P status, of paddy soils with slight decrease of total C, while a large amount of N and K applied has been released to the outer environments, suggesting considerable environmental impacts due to agricultural management. In conclusion, conversion to a system with highly efficient use of external nutrient inputs combined with organic matter-conserving strategies is required to secure sustainable food production while restoring the environment during the decades to come.

##### AMMONIUM AND NITRATE BLUEBERRIES CV. BLUE RIBBON ABSORPTION AT THE FIRST SIXTY DAYS RESPONSE OF ESTABLISHMENT ON A SOIL: PRELIMINARY RESULTS

A NARIO<sup>1</sup>, C BONOMELLI<sup>2</sup>, M I ARIAS<sup>2</sup>, K ROJAS<sup>2</sup>, P BLANC<sup>1</sup>

<sup>1</sup> Comision Chilena de Energia Nuclear, Centro de Tecnologías Nucleares en Ecosistemas Vulnerables, Santiago, CHILE

<sup>2</sup> Pontificia Universidad Católica de Chile, Departamento de Fruticultura y Enología, Fac. Agronomía y Sistemas Naturales, Santiago, CHILE

Blueberry is recognized as a “natural health package” since its fresh fruits have multifunctional nutritional value with a high content of anthocyanins as antioxidants. One of the important nutrients in the plant growth is nitrogen (N), as a component of amino acids, proteins, nucleic acids, chlorophyll, and several metabolites, finally on fruit growth and reserves for next season.

Inorganic N (nitrate or ammonium) are absorbed from roots and translocated to the different parts of the plants. It seems that blueberry shows better results in the presence of NH<sub>4</sub><sup>+</sup>, but other studies also reported a better growth in the vegetative stage when an ammonium and nitrate ratio is applied 1:1.

Split N applications can extend the time of N bioavailability for plant uptake and have been reported to promote plant yield or growth compared to a single application.

Chile has 15,601 hectares (2021-2022) planted with Highbush blueberries, with an export volume of 87,585 tons (2022-2023), an 18% less from the previous season. This reduction is an effect of several climatic and productive factors, so new varieties accomplishing export fresh requirements must be used.

In regard with forms and timing of nitrogen application, some studies show information in the blueberries production stage with limited information on the N demand for plants growth and new cultivars in early stages.

The aim of this study is to determine the effect of timing and form of nitrogen fertilizer (NH<sub>4</sub><sup>+</sup> or NO<sub>3</sub><sup>-</sup>) application on physiological and growth variables and N recovery in Blueberries cv Blue Ribbon and soil after the first 60 days of establishment, using <sup>15</sup>N isotopic techniques.

Preliminary results showed that nitrogen fertilization influences the growth of Blueberries. Applying ammonium was obtained the highest and significant growth expressed in shoots length and weight, number of leaves and weight, and roots weight. Split application resulted in a better response for some growing parameters. To determine blueberries recoveries soil and plant fractions are under <sup>15</sup>N analysis.

**Keywords:** NH<sub>4</sub>,NO<sub>3</sub>,<sup>15</sup>N atom excess,Nitrogen efficiency,Blueberries

8.03 133541 - Sustainable Soil Nutrient Management: Implications for Food, Environment, and Ecology

PHOSPHORUS FORMS IN VERMICOMPOST AND EVALUATION OF ITS USE AS REPLACEMENT OF MINERAL PHOSPHORUS FERTILIZING UNDER DIFFERENT SOIL MANAGEMENT PRACTICES.

J NIETO CANTERO, A GARCÍA-LÓPEZ, R RECENA, J M QUINTERO, A DELGADO

Departamento de Agronomía, ETSIA, Universidad de Sevilla, Seville, SPAIN

The recycling of nutrients by composting organic materials from agricultural waste comes necessary in a circular economy context. Vermicomposting is a product enriched in humus and available phosphorus (P). However, P forms present in vermicompost, and the impact on biogeochemistry of P in soils is still unknown. This work aimed at studying the forms of P present in vermicompost through <sup>31</sup>P NMR spectroscopy as well as the contribution of vermicompost on plant nutrition growth under soils with different management and depth. For this purpose, a pot experiment with wheat and vermicompost as P source (10 and 20 mg kg<sup>-1</sup>) was conducted with soil from different soil managements systems (conventional tillage (CT) and non-tillage (NT) and depths (0-5 and 20-40 cm). Results showed that 35-55% of the P applied to soil as vermicompost remains in organic forms. Vermicompost showed a higher use efficiency of P compared to mineral fertilization as similar biomass production was obtained between vermicompost and mineral fertilization with a 61 % reduction of P uptake. However, the efficiency of vermicompost, expressed as replacement value (RV), is deeply affected by soil management in superficial soils ranging values from -132% to 124 %, while a constant value of RV around 80% was found in sub superficial soil. Differences can be explained by the fact that the main differences produced by different soil management systems are observed in topsoil. Vermicompost application modified microbiological communities, increasing biodiversity expressed as Shannon Index, a 6% compared to mineral fertilization, as well as the functionality of soil boosting in P-cycle enzyme activities further enhancing the conservation tillage effect. Fe and Zn absorption was also affected by vermicompost and no-till management, leading to biofortification of wheat yield. It can be concluded that vermicompost was a suitable substitute for mineral fertilization presenting a higher efficiency of P management and further benefits can be expected when it is used over soils where conservation agriculture techniques are used.

Figure 1: Effect of P source (P, no phosphorus was applied, P1, mineral P and V, vermicompost) on P uptake by plants, significant according to ANOVA at p-value < 0.0001 (a) and the available P extracted as Olsen P after plant harvest, significant according to ANOVA at p-value < 0.0001 (b). Means with different letter were significantly different according to the Tukey's test at p-value < 0.05.

Figure 2: Replacement value of vermicompost based on the response to mineral phosphorus (CT, Conventional Tillage; NT, No Tillage; 0-5 and 20-40, surface and deep bottom soil). Different letters indicate significant differences. Statistical differences were calculated for each tillage system independently. Error bars indicate p-value were < 0.05 and 0.0105.

Figure 3: Zn concentrations in wheat spikes (mg kg<sup>-1</sup>) expressed in the upper (surface) and lower (bottom) tillage systems (CT, Conventional Tillage; NT, no Tillage). Depth 0-5 or 20-40 cm depth (bottom) and fertilizer (NPK, as P fertilization, P1, mineral P fertilizer and V, Vermicompost) p-value < 0.0505.

Figure 4: Interaction of soil depth and soil tillage system over P1 and P2a expression in the soil (ppm) between the elements in wheat spikes (CT, Conventional Tillage; NT, no Tillage). Depth 0-5 or 20-40 cm depth (bottom). p-value was 0.0025 and 0.0001 for P1e and P2a respectively.

##### EVALUATION OF GHG AND AMMONIA EMISSIONS AND FERTILITY IN AGRICULTURAL SOILS TREATED WITH DIFFERENT LIVESTOCK WASTES: CASE STUDIES IN FARMS IN THE PROVINCE OF BRESCIA

V SERGI, V CAPRARULO, G FERRONATO, A SIMONETTO, G GILIOLI, L GIAGNONI

University of Brescia - Department Civil, Environmental, Architectural Engineering and Mathematics (DICATA, Brescia, ITALY)

Organic fertilization by livestock wastes can be a suitable option to reduce the use of chemical fertilizers. However, the application of livestock wastes requires attention to the potential environmental impacts due to the emissions of greenhouse gases (GHGs) and ammonia and nitrate leaching.

We have selected a set of experimental fields in farms of the province of Brescia (Lombardy, Italy) characterized by different soil type, tillage, fertilization and irrigation methods. The experiment is designed to compare the effect of the application of livestock wastes (slurry, digestate and manure) in comparison with urea-based fertilization during maize growth season (2022 and 2023) on the GHGs (CO<sub>2</sub>, CH<sub>4</sub>, and N<sub>2</sub>O) and ammonia (NH<sub>3</sub>) emissions from agricultural soils.

GHGs and ammonia fluxes were measured weekly by static chambers connected to FTIR analyser. Results showed that the highest values of CO<sub>2</sub>, CH<sub>4</sub>, and NH<sub>3</sub> emissions were measured during the spreading of slurry and digestate compared to untreated soil (control). CO<sub>2</sub>, CH<sub>4</sub>, and NH<sub>3</sub> emissions from soils treated with manure were comparable to those of the control. The incorporation of slurry and digestate drastically reduced CH<sub>4</sub> and NH<sub>3</sub> emissions. No significant differences were observed in CO<sub>2</sub> emissions from different plots during the maize growth season. The peak of N<sub>2</sub>O emission was observed only after the use of urea-based fertilizer in all plots.

Data collected on the nutrient fluxes in the experimental field combined with soil characterization in terms of physio-chemical and biological properties will allow the understanding of the processes involved in GHGs and ammonia formations in soils and will help determine the factors influencing these emissions and soil quality. Data will also be used for calibrating and validating soil carbon and nitrogen biogeochemical models useful for improving farm sustainability. The use of validated modelling tools can support the development of efficient strategies to reduce the environmental impacts of agricultural practices and evaluate the efficiency of sustainable farming practices reducing nutrient losses.

##### NITROGEN REMOVAL ESTIMATION AND NON-POINT SOURCE NITROGEN LOADING MANAGEMENT IN MULTI-WATER AGRICULTURAL WATERSHEDS

X YAN

Institute of Soil Science, Chinese Academy of Sciences, Nanjing, CHINA

Water bodies such as ditches, ponds, streams, and lakes are important for eutrophication control through sediment denitrification nitrogen removal, especially in multi-water agricultural watersheds. However, quantifying N removal in water bodies is challenging due to the high background atmosphere N<sub>2</sub> concentration and the heavy burden of field surveys, leading to a decoupling of upland N management and water quality improvement. Here, we first conducted a one-year field study to investigate the N removal rate in small area water bodies (ditches, ponds, and streams) within a typical intensive agricultural area. We found that various N removal (from 0.22/d in streams and 0.48/d in vegetated ditches) could be well modeled by the concentrations of water dissolved organic carbon (DOC) and dissolved oxygen (DO). In addition, we developed and validated an innovative nonlinear model for big area water bodies (e.g., lake) N removal estimation by linking the N removal rates with remote sensing-derived variables (chlorophyll-a, chromophoric dissolved organic matter, and lake surface water temperature). Based on all these models, we estimated that an annual average of 32,100 t N/yr was removed in Lake Taihu from 2011 to 2020, accounting for 53% to 66% of the total lake N loading. The remaining N loading after denitrification removal in Lake Taihu would be approximately 2.37 mg N/L, and 7,900 t N/yr of lake N loading originating from the landscape still needs to be removed to meet the target of class IV water quality (1.5 mg N/L). We recommend implementing artificial management measures, such as vegetation, to enhance the N removal capacity of water bodies. However, the caution must be exercised in measures like concrete linings in ditches, as they can hinder N removal. Overall, our study highlights the importance of multidisciplinary intersections in managing soil nutrient losses to mitigate eutrophication and achieve water quality goals.

Although variations of microbial communities and residue components were detected during the decomposition of monospecific and mixed plant residue, little is known about the response of specific taxa to different residue types and their interactions with other microorganisms. In this study, we compared the decomposition dynamics, recruited microbial community, and lignocellulolytic genes during decomposition of leguminous milk vetch (MV), non-leguminous rice straw (S), and their mixed residue (SMV) to reveal the mechanisms of microbial-driven residue decomposition. The residue remaining weight and their main lignocellulose component contents exhibited different periodic dynamics during decomposition, while SMV maintained a relatively high decomposition rate particularly in early stages. Actinobacteria, Alphaproteobacteria, Gammaproteobacteria, and Sordariomycetes were enriched in S treatment. Eurotiomycetes and Bacilli were enriched in MV treatment, while Mucoromycetes was enriched in SMV treatment. Co-decomposition of residues increased the alpha diversity of microbial community and enriched the Mucorales by increasing its niche breadth. Redundancy analysis (RDA) revealed that Mucorales was a key functional taxon with high lignocellulolytic potential. In conclusion, our study shows that co-decomposition can widen the niche breadth of certain species facing competitive condition during decomposition, recruit more functional groups, maintain the decomposition efficiency, and finally promote residue decomposition.

<sup>3</sup> Department of Agricultural, Food and Environmental Sciences, University of Perugia, Perugia, ITALY

<sup>4</sup> Department of Pharmaceutical Sciences, University of Perugia, Perugia, ITALY

Modern agriculture can exert a detrimental impact on natural ecosystems. Cropping systems are very demanding in terms of chemical fertilizers, plant growth promoters, water, and herbicides/pesticides. Anthropogenic activity can release pollutants into the environment, leading to unsustainable consumption of natural resources, affecting soil fertility and biodiversity and exacerbating climate change. More efficient forms of fertilization should be developed to reduce the use of chemical fertilizers.

In this study, lignin, bioactive compounds and nutrients were extracted from the by-products of the olive oil chain, i.e. pomace and olive mill wastewaters, and valorized by producing also biopolymeric compounds (BPCs) with enhanced controlled-release properties. The efficiency of BPC to release nutrients over time was studied in a 90-days soil incubation column leaching experiment, and the results were compared to those observed for a traditional NPK fertilizer and olive mill wastewaters. BPC was the most efficient in slowly releasing nutrients, in terms of soluble N, P and K, compared to the other treatments. Analysis of water-extractable organic C and CO<sub>2</sub> respiration revealed that although BPC increased the available content of C in the soil and leachates, it nevertheless resulted in the lowest emissions of CO<sub>2</sub> after 90 days compared to the other treatments. The microbial activity, estimated by analyzing the fluorescein diacetate hydrolysis, revealed that BPC stimulated the greatest hydrolytic activity. Such a result can be explained based on the slow degradation of BPC and its continuous release of nutrients. The study shows the possible use of BPC in agriculture, due to its efficient slow release of nutrients over time, compared to the other fertilizers investigated. Therefore, its use could reduce the need to fertilize the soil frequently and decrease CO<sub>2</sub> emissions, representing a high-added value biofertilizer.

##### SUSTAINABLE SOIL CROPPING MANAGEMENT STRATEGIES TO ENHANCE THE BIOACTIVE COMPOUND PRODUCTIONS OF TANACETUM BALSAMITA L.

A BONETTI<sup>1</sup>, M GRATTACASO<sup>1</sup>, S DI LONARDO<sup>1</sup>, E TASSI<sup>2</sup>, F BRETZEL<sup>2</sup>, R PINI<sup>2</sup>, L. ..P. D'ACQUI<sup>1</sup>

<sup>1</sup> Institute for the research of terrestrial ecosystems - CNR, Florence, ITALY

<sup>2</sup> Institute for the research of terrestrial ecosystems - CNR, Pisa, ITALY

The use of biostimulants and/or biofertilizers has acquired considerable importance and can contribute to the sustainable management agriculture, reducing the use of chemical fertilizers, pesticides, and water. In this research, conducted in the framework of ReCROP project, financed by the European PRIMA program, the development of sustainable agroecosystem strategies for the Mediterranean area has been faced to increase the resilience of agrosystems to climate change, to reduce the chemical fertilizers, and to improve soil health. One of the Italian experimental trials aimed to evaluate the enhancement of the physical and chemical soil properties and the increase of the bioactive compound production through the combined use of bioinoculants and amendments (i.e. compost) in *Tanacetum balsamita* L., an aromatic plant well-known in Tuscany region (Italy). This species has remarkable medicinal properties, including hepatoprotective, spasmolytic, carminative, and antiviral effects. These qualities results from a high presence of bioactive products, such as polyphenols and essential oils . Results of the first growing season highlighted how the treatments involving bioinoculant and bioinoculant + compost contributed to increase the plant biomass (in terms of number of leaves per plant and mean plant weight) and photosynthetic apparatus (higher chlorophyll a and b content), while total phenols exhibited no significant variations between treatments. Relating to nutrient content, the major content of chlorophylls and then of higher plant biomass in these treatments could be explained because of the higher content of P and Mg in plants due to their high bioavailability of into soils.

##### EFFECT OF DIFFERENT SOURCES OF SILICON ON PLANT AVAILABLE SI POOLS AND PHYTOLITH AND PHYTOC CONTENT IN AEROBIC RICE

M ANJUM<sup>1</sup>, P NAGABOVANALLI<sup>2</sup>

<sup>1</sup> Dr. Kalam Agricultural College Kishanganj, KISHANGANJ, INDIA

<sup>2</sup> University of Agricultural Sciences Bangalore, BENGALURU, INDIA

##### Body

Rice plants contain a large amount of silicon (Si) in the form of phytolith. Application of exogenous Si sources has been reported to be effective in enhancing Si uptake and increasing phytolith and PhytOC content (Anjum and Prakash, 2023). Various silicon (Si) sources have been reported to be effective in terms of their effectiveness on rice yield and plant-available Si. Nevertheless, comparative study of different sources of Si on phytolith and PhytOC content and soil properties is poorly known. A field experiment was carried out to investigate the effect of three different sources of exogenous Si, i.e., diatomaceous earth (DE), silicic acid (SA) and rice husk biochar (RHB) on 1) plant phytolith, C content in phytolith and PhytOC content in different rice organs; 2) relationship between plant phytolith, C content in phytolith, PhytOC content, and soil properties (soil physicochemical properties and readily soluble silicon pools. Different Si sources produced significantly higher phytolith, PhytOC content and readily soluble Si pools (CCSi, AASi and ASi) than the control (RDF), with treatment receiving 4 t RHB ha<sup>-1</sup> outperforming the other treatments. Phytolith and PhytOC production were found to be significantly correlated to soil organic carbon (OC), available nitrogen (N) and potassium (K), 0.01 M CaCl<sub>2</sub> extractable Si (CCSi) and amorphous Si (ASi) content in the soil. Redundancy analysis showed that treatments receiving 4 t RHB ha<sup>-1</sup> have a stronger relationship with the CCSi and ASi which majorly contributed to the higher phytolith and PhytOC production. Through these positive effects, we conclude that practices such as Si fertilisers and especially RHB application have great potential for phytolith production and PhytOC sequestration.

##### BIOLOGICAL ACTIVITY AND CHEMICAL VARIATION OF PHOSPHORUS IN HUMID REGION SOILS UNDER LONG-TERM IRRIGATION WITH SECONDARY TREATED WASTEWATER

B CASTILLO, J REGAN

Department of Civil and Environmental Engineering, Pennsylvania State University,, University Park, USA

Water scarcity is a critical global issue, particularly in regions experiencing high population growth and agricultural demands. To address this challenge, the reuse of treated wastewater (TWW) for various purposes, including, agriculture, forestry, and industry, has gained significant attention as a potential solution. While TWW irrigation offers benefits for agroforestry lands, addressing potential adverse impacts on soil properties is crucial. It is essential to emphasize that the use of TWW and its effect on soil properties can alter sorption and desorption processes of essential nutrients, particularly phosphorus (P). This situation is a concern due to potentially leading to eutrophication in freshwater, disrupting the ecological balance. Studies in arid and semiarid areas show that TWW irrigation can affect, physicochemical and biological properties. However, the findings may not be directly applicable to humid region soils due to the influence of different climatic factors, which can have varying effects on the biogeochemical cycle of P in agroforestry soils from areas with warm and rainy summers and no dry seasons. toward the development of land management strategies that reduce P losses from agroecosystems, this study aims to evaluate how long-term irrigation with secondary TWW in agroforestry soils from humid regions has affected the P speciation in soils, the sorption-desorption dynamic, and the activity of key enzymes associated with the P cycle compared to non-irrigated soils. To evaluate that, forest and agricultural soil samples were collected from The Living Filter sites in Centre County, Pennsylvania, United States, which have been irrigated with TWW over the last sixty years. In general, the results showed that soils subject to TWW irrigation altered their physicochemical properties such as, pH, organic carbon, electrical conductivity, and P concentration. Additionally, sorption-desorption experiments revealed that TWW-irrigated soils are less subjected to adsorb P, but they can desorb higher P concentrations than soils non-irrigated. Regarding the biological parameters, alkaline and acid phosphatases, pyrophosphatases, and phosphodiesterase activities increased in soils subjected to TWW irrigation.

<sup>4</sup> Rodale Institute, Kutztown, USA

Organic farming, deeply rooted in traditional agricultural practices, has witnessed a profound evolution over the last century. Transitioning from a grassroots initiative resisting the industrialization of agriculture to a global industry, organic farming now plays a pivotal role in addressing contemporary challenges related to environmental health, sustainability, and food safety. With a growing consumer demand for fresh organic products, this presentation provides a comprehensive overview of the organic farming landscape, underscoring its historical evolution, current trends, and the intrinsic benefits associated with organic practices. A key emphasis is placed on the role of organic fertilizers, detailing their types, benefits, challenges, and potential in bridging the yield gap while maintaining environmental stewardship. It also highlights the challenges faced by organic farmers, such as nutrient management, pest and disease control, and market access, offering potential strategies for mitigation. Concluding with a perspective, recommendations, and directions for future research, this presentation underscores the urgency for innovations, technological advancements, and a deeper understanding of organic practices to ensure the sustained growth and viability of organic farming in the global agricultural paradigm.

Several mechanisms may be involved in the genesis of sorted patterned ground, though the sorting by different frost heave due to freeze-thaw cycles is favored by theoretical considerations. The soil freezing and thawing are generally associated with shallow permafrost presence affecting surface cryoturbation phenomena. Several studies hypothesized the occurrence of permafrost in the Majella Massif (central Apennines, Italy) because of the presence of periglacial landforms (patterned ground, kettle holes, rock glaciers), although no direct observations have been reported. Therefore, this work aimed to investigate the genesis and preservation of patterned ground in the upper part of the Majella Massif through the detection of soil and air temperatures and soil morphological, mineralogical, and physicochemical characteristics.

Mean annual ground surface temperature and winter equilibrium temperature suggested that permafrost, if present, would be at a depth >2m. A relict form, deriving from shallower permafrost present in ancient climatic phases, may have been preserved by an air circulation mechanism at such a depth that cannot affect ongoing superficial cryoturbation processes. Although the formation of patterned ground has been ascribed to permafrost-driven processes that occurred in ancient climatic phases, the preservation is related to shallower phenomena associated with freeze-thaw cycles of the upper soil layers and the water-holding capacity of the soil.

**Keywords:** Sporadic permafrost, Miniature patterned ground, Cryoturbation, Water-holding capacity

Patagonia is the world's only continental territory south of 38° S. Comprises the southern section of the Andes in the west and displays steppes to the east. In the steppe there are unique ecosystems called Vegas. These areas are special because have distinctive characteristics i.e., are within the most extreme rainfall gradient in the world and their formation is closely linked to the last glacial and post-glacial era. Therefore, there isn't a comparable situation in the Northern Hemisphere. Vegas are wetlands that provide a large number of ecosystem services, being the main source for food for livestock. Despite that Vegas are important ecosystem, not much information about their soil function exists. The aim is to highlight the relevance of the soil functions of a Vega in Chilean Patagonia at different scales; from soil porosity (small scale) to watershed level (large scale). The present study was established in the Southernmost of Chile. Undisturbed soil samples were taken at depth H1=5 cm, H2=30 cm, H3=80, to classify soil type and to evaluate the morphological and physical properties of seven pits across the Vega. In five of those pits soil water content and soil matric potential sensors were installed. A piezometric station was installed in the center of the Vega and the data of the nearest weather station were used. There is a large spatial variability of soil type and their physical properties (i.e., conduction of water and air, shrinkage capacity). Each sector of the Vega has a specific function, while the summit and footslope are areas that can provide water by runoff, the soils in the center of the Vega have the capacity to store large quantities of water, which permit to large hydric deficits in spring and summer. In addition, the soil moisture depends largely on ETo and groundwater in the center of the Vega. Also, Vegas is part of watersheds, which are recharged with water in mountain sectors.

<sup>5</sup> BIOME Lab, Department of Biological, Geological and Environmental Sciences, Alma Mater Studiorum University of Bologna, Bologna

Some regions are particularly sensitive to climate change and the Altai Mountains (Russia) are showing unequivocal signs. The mean annual temperature in the area has increased by 1.3–1.7 °C in the last century. According to our measurements, the glacier lost about 12 m per year during the last 50 years. Our work is focused on the analysis of the soil microbiota (archaea, bacteria, and fungi) along a chronosequence in the first 600 m of the Maliy Aktru glacier's forefront of Altai Mountains and on the microorganism (fungi and prokaryotes) associated to the pioneer plant *Saxifraga oppositifolia* L. Our study shows that both soil and *S. oppositifolia* fungal communities are differently distributed in the glacier retreating area with higher relative abundances of ascomycetes at early successional stages. The ascomycetes are gradually replaced by basidiomycetes at incremental distances from the glacier forefront. Symbiotrophs and specifically ectomycorrhizal fungi were found to increase their relative abundance both in soil and plant rhizosphere at more than 350 m from the glacier forefront. The data relating to the distance and the trophism of the fungal communities were strictly correlated to some soil parameters (i.e. cation exchange capacity and some cations such as Mg<sup>2+</sup> and Ca<sup>2+</sup>). Concerning prokaryotic communities (bacteria and archaea) our results showed an increase of the fraction of archaea along the transect and more in detail from 400m from the glacier forefront both in bulk and rhizospheric soil.

<sup>2</sup> University of Zimbabwe, Harare, ZIMBABWE

Realizing soil health monitoring with farmers shows tremendous potential in East and Southern Africa to enhance climate resilience, ameliorate natural resources and support sustainable production. However, there are many barriers to local access as digital tools, data systems and knowledge sharing often remain out of reach. This is particularly so for women and marginalized groups. In Malawi, Ethiopia and Nepal progress has been made in collaborating local communities to work with researchers, public and private partners to address these barriers and engage indigenous and science-based monitoring and problem solving for soil health. Adoption of soil health measures developed locally and shared more broadly will be discussed. These include soil organic matter technologies, zinc nutrition amelioration and nitrogen targeting practices. Audience participation is welcome, to consider lessons learned and next steps.

<sup>4</sup> Universitat Politècnica de València. Department of Chemistry, VALENCIA, ESPAÑA

The use of green covers in Mediterranean crops has gained importance in recent decades. The goal is to enrich agricultural soil by increasing organic matter and soil nutrients, reducing erosion and biodiversity loss, creating an ecosystem in conjunction with cultivated plants. This study is conducted in Valencia region (Spain) with different green covers in persimmon orchards (*Diospyros kaki*, Thumb). We monitored the green covers using moisture sensors and spectral images. The trial is focused on gramine, leguminous and flowers, using species such as *Festuca*, *Medicago*, *Onobrychis*, *Trifolium*, or *Vicia*, among others. Ten plots were studied: two of them sown with different type of plant covers, five with spontaneous covers, and three with bare soil in which an herbicide treatment for weed control was carried out. Soil samples were obtained by systematic sampling at a total of 71 sites, within 15 cm of the surface. Comparing the different green covers with plots of bare soil, considering their contribution to soil in terms of soil moisture, temperature, electrical conductivity, organic matter, and biodiversity as well as the improvement of other properties. Results show relevant improvements in these variables, the green cover with Mix Flowers has positive balance in soil moisture, better than Leguminous and Gramineae, nevertheless all of them have a beneficial effect in soil moisture while in orchards with bare soil there is more water stress than in the orchards with green covers. This study aims to be a first step in facilitating farmers' efforts related in green cover management.

##### INNOVATIVE METHODS AND PRACTICAL CONSIDERATIONS FOR SCALING SOIL HEALTH MEASUREMENTS

E. RIEKE, D. BAGNALL, C. MORGAN, D. LIPTZIN, W. HONEYCUTT

Soil Health Institute, Morrisville, NC, USA

Over the past few decades, a wide variety of soil health indicators have been developed by researchers and commercial laboratories to track how changes in agricultural management impact soil function. While the plethora of indicators may benefit the scientific community, the variety of measurements can complicate cross-study interpretations and overwhelm the non-scientist wanting to monitor their soil health. In 2019, the North American Project to Evaluate Soil Health Measurements was conducted to identify a minimal suite of soil health indicators applicable for measuring soil health commercially -- facilitating scalability. Factors considered when selecting indicators included: responsiveness to agricultural management practices that exemplify soil health, cost, availability, and redundancy in terms of linkage to soil function. As a result of these assessments, the following minimum suite of soil health indicators is recommended for agricultural soils across North America: 1) soil organic carbon concentration, 2) carbon mineralization potential, 3) aggregate stability, and 4) predicted available water holding capacity. Furthermore, a novel modality for measuring aggregate stability will be described, specifically the Slakes phone app. Our goal is to remove the barrier of sending samples to commercial laboratories for analysis, thereby opening doors for low-cost research, connecting non-scientists with soil health and enabling agricultural stakeholders to measure and monitor improvements in soil function with improvement in management.

**Keywords:** Scale, Soil organic carbon, Aggregate stability, Carbon mineralization, North America

##### PROPOSITION FOR A METHODOLOGICAL FRAMEWORK AND PROTOTYPE MRV TOOL FOR CROPLAND C STOCK CHANGE ASSESSMENT AT HIGH RESOLUTION OVER LARGE REGIONS

A. IHASUSTA <sup>1</sup>, A. AL BITAR <sup>1</sup>, T. WIJMER <sup>1</sup>, L. ARNAUD <sup>1</sup>, V. ANTONENKO <sup>1</sup>, A. GERAUD <sup>1,2</sup>, R. FIEUZAL <sup>1</sup>, E. CESCHIA <sup>1</sup>

<sup>1</sup> CESBIO, Université de Toulouse, CNES/CNRS/INRAE/IRD/UT3, Toulouse, FRANCE

<sup>2</sup> NetCarbon, Bordeaux, FRANCE

Increasing soil organic carbon (SOC) stocks is a well-identified climate change mitigation solution. However, accurate and extensive estimation of cropland SOC stock changes for National Inventories, for the Common Agricultural Policy or the voluntary carbon market with in-situ measurements exclusively would be too costly. Hence, soil or coupled plant/soil models are often used to quantify SOC stock changes but these models make many simplifying assumptions and lack accuracy when assessing the effect of the spatial variability in biomass production on SOC stock changes. Therefore, Paustian et al. 2019 and Smith et al. 2020 have proposed theoretical frameworks for the Monitoring, Reporting and Verification (MRV) of agricultural SOC stock changes relying on the combination of high-resolution remote sensing data, field information, and physical models.

We present here both the methodological framework and the Operational Processing Chain (OPC) AgriCarbon-EO that provides the biomass, water and carbon budget components of agricultural fields at 10m resolution and at regional scale. The OPC has been optimized to assimilate high resolution optical remote sensing data (Sentinel-2) into a radiative transfer model and a coupled crop/soil model. First, the application of a spatial Bayesian retrieval approach to the PROSAIL radiative transfer model provides Leaf Area Index (LAI) with its associated uncertainty for each date of satellite acquisition. Second, LAI is assimilated into the SAFYE-CO2 crop model using a temporal Bayesian retrieval that enables the calculation of the biomass, CO2 and water fluxes components with their associated uncertainties. Next the biomass simulated by SAFYE-CO2 is used to compute the carbon input in the AMG soil model. The outputs were validated for several cropping years with independent in-situ biomass and CO2/water fluxes data measured at several flux towers in Europe. We show the added value of assimilating high-resolution satellite data in driving the crop/soil models to account for the impact of complex processes that are embedded in the LAI signal on the biomass and carbon/water budgets components estimates.

#### 8.07 133620 - Soil Ambitions: Driving soil health into national and international policy

##### ASSESSING THE RELEVANCE AND THE FEASIBILITY OF CANDIDATE POLICY RECOMMENDATIONS FROM THE EJP SOIL PROGRAMME TO STRENGTHENING THE EU SOIL STRATEGY

I. CRISCUOLI, F. GALIOTO, I. FALCONI, A. MARTELLI, G. DARA GUCCIONE

CREA Research Centre for Agricultural Policies and Bioeconomy, Rome, ITALY

The EU Soil strategy for 2030 has the objective to restore degraded and contaminated soils, achieve carbon removals in the LULUCF sector, protect surface and groundwater, reduce nutrient losses and use of chemical pesticides. In this context, the proposals of a regulation establishing a “Union certification framework for carbon removals” and of a directive on “Soil monitoring and resilience” have been set out in the last year.

The European Joint Programme on Soil (EJP SOIL) is a vast research program about climate-smart sustainable management of agricultural soils which involves 26 partners with different expertise from 24 European countries. One of the aims of the Programme is to contribute to strengthening the abovementioned regulatory proposals.

Considering that, a mixed-methods approach was used to evaluate how the results of EJP SOIL could be incorporated into policy recommendations. The method involved a quantitative (multi-criteria assessment, MCA) and a qualitative analysis.

Specifically, EJP SOIL scientists proposed a list of recommendations for the two EU proposals and then have prioritized them. The most relevant recommendations were then submitted to national and EU policymakers for an assessment based on the following criteria:

- Feasibility: existence of the facilities that allow implementing the recommendation at the EU level;
- Effectiveness in achieving the desired objectives of the regulations;
- Internal integrity: relevance for the EU soil strategy;
- External Integrity: contribution to mitigate perverse effects of other policies (e.g. promoting the over-exploitation of agricultural soils).

Policy makers were first asked to weigh the criteria based on their importance, then to score the recommendations with respect to each criterion and finally to explain the reasons behind their choices. A subsequent focus group will allow to disentangle divergences of opinions and consolidate key messages. Results allow identifying key strengths and weaknesses of each recommendation and their relevance in addressing the EU Soil strategy, possible conflicts with already existing EU policies and the key governance changes needed to implement the envisaged policy solutions.

**Keywords:** Policy recommendations, EU Soil strategy, Multi-Criteria Assessment, Carbon removals, Soil monitoring law

##### INVESTIGATING THE INTERPLAY OF DIFFERENT POLICY INSTRUMENTS IN ADDRESSING AGRICULTURAL SOIL HEALTH CHALLENGES IN THE EU AND TÜRKIYE

F. GALIOTO, F. VARIA, G. DARA GUCCIONE

Consiglio per la ricerca in agricoltura e l'analisi dell'economia agraria, Politiche e bioeconomia,, Rome, ITALY

This study focuses on the analysis of the policies addressing soil health challenges, which have been recently designed and implemented in six EU countries and in Türkiye. In this regard, the researchers involved in the study developed a common research framework consisting of five key policy areas: Incentivising the adoption of sustainable practices, with special reference to voluntary measures promoted by agricultural policies (i.e., the CAP for EU countries and IPARD for Türkiye); Enabling participatory processes, with special reference to regulations empowering collective actions (e.g. Eco-Regions, Bio-districts, Land associations, Rural districts); Regulating the protection of the environment and the landscape, which consists of both nitrate, water, and biodiversity directives as well as regulations and rules aimed at protecting landscape features; Co-creation and sharing of innovation and knowledge, with special reference to EIP-Agri Operational Groups, lighthouses and living labs and advisory services; Triggering new market opportunities, which encompasses rules on geographical indications of origin, short food chain initiatives, voluntary certification schemes.

A comparative analysis based on descriptive statistics and qualitative information is implemented to highlight convergences and divergences of policy interventions, and to assess the relevance of the policies compared to contingent soil health challenges.

The results reveal that the promoted sustainable practices are not often accompanied with robust conditionality requirements, with the risk of compromising effectiveness (at least for some types of farming systems). Moreover, the different national soil health strategies are generally still characterised by several weaknesses, partly due to the flexibility with which EU regulations and directives can be implemented, which has often led to weaken commitments, and partly due to deliberate infringements, with direct consequences on the governments' capacity to monitor and control compliance. Conclusions provide a summary of the main findings, discuss the limitations of the examined national policies, and provide some policy recommendations to address the existing shortcomings in the current plans due to the lack and poor design of relevant policy instruments.

<sup>5</sup> Confagricoltura, Rome, ITALY

<sup>6</sup> Czech University of Life Sciences, Prague, Czech Republic, Prague, CZECH REPUBLIC

In recent years, the escalating impacts of climate change and environmental degradation have intensified the challenges faced by agri-food systems globally. Within the European ECO-READY Project, a critical examination was conducted to assess the alignment of existing policies with resilience measures for Climate Change (CC), Biodiversity (BD), and Food Security (FS). Using Eclipse synthesis methods, Expert Consultation and Systematic Map, scientific data were linked to EU policies, including Common Agricultural Policy (CAP) and the Green Deal. Screening 150 documents revealed gaps between data and policy. Evaluation of EU policies and identification of gaps were performed using keywords related to CC, BD, and FS drivers and indicators. The proposal for Directive "Soil Monitoring Law", introduced in July 2023, outlines strategies for monitoring threats like erosion, floods, and biodiversity loss. This directive, in conjunction with the EU Soil Strategy for 2030, underscores the importance of sustainable soil management, restoration, and desertification prevention. The Communication on fertilizers (COM(2022)590) complements these initiatives by addressing issues of affordability, nutrient losses, and soil fertility. Nevertheless, identified policy gaps reveal opportunities for further inclusion. The study highlights the intricate relationship among above-ground vegetation, microbial communities, and soil characteristics, urging a deeper exploration of soil health aspects. The LUCAS initiative and the European Soil Data Centre (ESDAC) play key roles in providing essential data on land use, cover, and standardized soil information. Despite these advancements, certain aspects related to soil health need thorough examination. Recognizing their significance, focused goals and investments could enhance sustainable agricultural productivity. The Soil Monitoring Law advocates a comprehensive framework, promoting regeneration and standardizing sustainable soil management. An integrated approach, considering microbial communities, water management, climate change, and soil health, is crucial for promoting soil health, environmental resilience, and sustainable agriculture within FS, BD and CC pillars. Funded by the European Union's HORIZON-CL6-2022 research and Innovation programme under grant agreement N. 101084201. <https://www.eco-ready.eu>

<sup>3</sup> Università degli Studi di Torino, Torino, ITALY

<sup>4</sup> CREA, Roma, ITALY

The degradation of soils due to unsustainable management practices poses significant challenges to global agriculture and environmental protection efforts. Despite numerous soil-related policies and scientific advancements, soil degradation continues unabated. This is due to the vagueness of the proposals and the lack of effective operational instruments. In response to the need for an effective legal protection, Italian scientists under the umbrella of AISSA (association gathering all Italian association active in agricultural and forest sciences), and led by pedologists (SIPe), proposed a soil framework law adopted by the Italian Senate. This proposal, initially presented in 2013 and updated in 2022, aims to address the complex challenges of the sustainable soil use, emphasizing the preservation of soil health and ecosystem services. While the proposal has yet to be enacted into law, its integration of national and European environmental legislations and utilization of Spatial Decision Support Systems (S-DSS) represent innovative approaches to soil management. By fostering collaboration among stakeholders and overcoming institutional fragmentation, the proposed law offers a comprehensive framework for sustainable soil management. The demonstration of scientists engaging in the legislative process underscores the importance of addressing soil degradation in tackling climate change, protecting biodiversity, ensuring food security, and promoting human health. We hope that our effort will serve as a model for inspiring similar initiatives globally, emphasizing the critical role of update and smart legal mechanisms in protecting and managing the soil resources for today's challenges and for future generations.

8.08 133822 - Peatlands in a changing world

PEATLAND REWETTING IN OIL PALM PLANTATION OFFERS CLIMATE CHANGE MITIGATION BENEFIT THROUGH REDUCED CO<sub>2</sub> FLUX WITH NO EFFECT ON CH<sub>4</sub> FLUX

N NOVITA <sup>1</sup>, A ASYHARI <sup>1</sup>, R RITONGA <sup>1</sup>, A GANGGA <sup>1</sup>, G ANSHARI <sup>2</sup>, B KAUFFMAN <sup>3</sup>, A HOYT <sup>4</sup>, J BOWEN <sup>4</sup>, C PERRYMAN <sup>4</sup>, I ALBAR <sup>5</sup>

<sup>1</sup> The Nature Conservancy, JAKARTA, INDONESIA

<sup>2</sup> Tanjung Pura University, Pontianak, INDONESIA

<sup>3</sup> Oregon State University, Corvallis, USA

<sup>4</sup> Stanford University, Stanford, USA

<sup>5</sup> Indonesia Ministry of Environment and Forestry, Jakarta, INDONESIA

For decades, tropical peatlands in Indonesia have been deforested and converted to other land uses, mainly oil palm and forest plantations. Given their global importance as carbon sinks, there is a growing interest in rewetting and restoring degraded peatlands. Peatland rewetting may contribute up to 13% of Indonesia's total mitigation potential from natural climate solutions. However, to our knowledge, no comprehensive assessment has been performed to understand the overall dynamics from simultaneous measurements of annual CO<sub>2</sub> and CH<sub>4</sub> fluxes from rewetted Indonesian peatlands, particularly from oil palm plantations. In this study, our primary objective was to investigate the impacts of peatland rewetting on CO<sub>2</sub> and CH<sub>4</sub> fluxes along with associated soil physicochemical properties and relevant environmental variables. We conducted biweekly monitoring of CO<sub>2</sub> and CH<sub>4</sub> fluxes for one year period from secondary forests and oil palm plantations located in Mempawah and Kubu Raya regencies, West Kalimantan, Indonesia. We found that peatland rewetting significantly lowered peat CO<sub>2</sub> emissions with no clear shifts in CH<sub>4</sub> emissions. Rewetting drained oil palm plantations can significantly reduce heterotrophic respiration by 34% and total respiration by 20%. Extrapolating our results to the areas of degraded oil palm plantations in West Kalimantan and Indonesia suggests the reduction of emissions from successful peatland rewetting would be 3.9 MtCO<sub>2</sub> yr<sup>-1</sup> and 15.0 MtCO<sub>2</sub> yr<sup>-1</sup>, respectively. Nevertheless, our results indicate that rewetting drained oil palm plantations will not reach the reference emission in the secondary forest. Even though the water table in secondary forests was similar to that in rewetted oil palm plantations, total peat respiration was still higher in oil palm plantations. These highlight that peat conservation as well as peat rewetting are important to climate change mitigation actions in these critical forests of Southeast Asia.

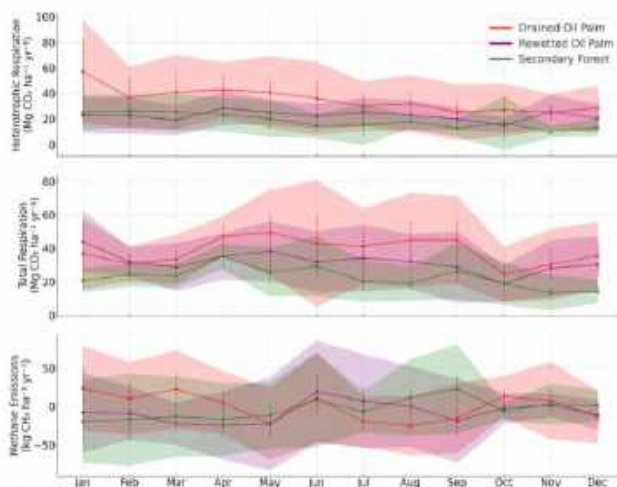

Figure. Summary of monthly measurement of GHG fluxes: (a) heterotrophic respiration; (b) total respiration; and (c) methane fluxes. The shaded area represents the standard deviation, while the vertical line represents the Standard Error Mean (SEM)

##### ASSESSMENT OF PALUDICULTURE APPLICATION ON FEN PEATLAND – A CASE STUDY FROM CENTRAL POLAND

M F JOEL, B GLINA

POZNAN UNIVERSITY OF LIFE SCIENCES- DEPARTMENT OF SOIL SCIENCE AND MICROBIOLOGY,  
POZNAN, POLAND

Paludiculture enables farmers to utilize wet or rewetted peatlands formally drained sustainably, reducing greenhouse gas emissions from these areas. The aim of the study was to assess the paludiculture application potential on fen peatland, located in the Chludowo village, ca. 20 km from Poznan (Central Poland). The studied peatland was drained at the turn of 19th and 20th centuries, for agricultural management (grassland). Soil samples were collected from genetic horizons from four soil profile in September 2023. In the field the soil morphology was described according to guidelines for soil description (IUSS Working Group WRB, 2022). In the laboratory after sample preparation (air drying, crushing in a mortar) the following properties were determined: the stage of secondary soil transformation, total carbon, total nitrogen, pH, calcium carbonate equivalent. Studied soil profiles were classified as Murshic/Drainic Histosol (profiles 1-3) and Gleysol (profile 4). We found out that soil profiles 1 and 2 exhibit a medium secondary transformation (W1 index: 0.68 to 0.707). In contrast, profiles 3 and 4, strongly transformed (W1: 0.77 to 1.33) due to higher drainage impact. This results were correlated with C/N quotient, which indicated higher soil organic matter mineralization in the uppermost soil layers. Obtained results on physico-chemical analysis indicated that paludiculture can be done to provide biodiversity value and preserve remained peat body in the area of the soil profiles 1-3. Due to it having high plant diversity dominated with reed vegetation and a drainage channel, showed a great potential for paludiculture. While it is highly recommended to apply conservation tillage method reducing the further depletion of soil organic matter content soil in the area of profile 4. Our findings pointed out that the minimum scenario for the study area should be to avoid further conventional agriculture management, as studied soils are the most vulnerable to secondary transformation. It is crucial to apply sustainable peatlands agriculture method, addressing biodiversity and climate change mitigation concerns.

##### THE SPRUCE EXPERIMENT: EFFECTS OF CLIMATE CHANGE ON NORTHERN FORESTED PEATLANDS

R KOLKA

USDA Forest Service Northern Research Station, Grand Rapids, USA

The Spruce and Peatlands Responses Under Changing Environments (SPRUCE) experiment is an ambitious ecosystem-level experiment that is testing the response of high-carbon northern peatland ecosystems to increased temperatures and elevated carbon dioxide. The experiment is being conducted in a black spruce peatland in northern Minnesota at the USDA Forest Service's Marcell Experimental Forest (MEF). SPRUCE is supported by the US Department of Energy and is a collaboration between Oak Ridge National Lab, the USDA Forest Service and 100's of other scientists from across the globe. Northern peatlands are an ecosystem considered especially vulnerable to climate change and responses to warming and interactions with increased atmospheric CO<sub>2</sub> concentration are anticipated to have important feedbacks on global climate. SPRUCE is evaluating the response of the existing plant and soil communities to a range of warming levels from ambient to +9°C, with and without elevated CO<sub>2</sub>, provided via large, open-top chambers. Belowground heating began in 2014, aboveground heating in 2015, and elevated CO<sub>2</sub> treatments commenced in June 2016 with our final field season in 2025. I will present results of SPRUCE, including treatment effects on greenhouse gas production, soil processes, and plant communities.

##### IMPACT OF LIMING ON PEAT DECOMPOSITION AND CO<sub>2</sub> EMISSIONS IN OIL PALM PLANTATIONS ON TROPICAL PEATLAND IN SARAWAK, MALAYSIA

N U MICHAEL BRENDEN<sup>1</sup>, R ABDULLAH<sup>2</sup>, F. .E. SANGGOK<sup>1</sup>, L MELLING<sup>1</sup>

<sup>1</sup> SARAWAK TROPICAL PEAT RESEARCH INSTITUTE, LOT 3022 KUCHING SAMARAHAN EXPRESSWAY, 94300 KOTA SAMARAHAN, SARAWAK, MALAYSIA, SARAWAK, MALAYSIA

<sup>2</sup> INSTITUTE OF BIOLOGICAL SCIENCE, FACULTY OF SCIENCE, UNIVERSITY MALAYA, 50603 KUALA LUMPUR, KUALA LUMPUR, MALAYSIA

Peat soil, typically problematic for agriculture due to its acidic nature and low fertility, presents unique challenges. In tropical peatlands, liming is a prevalent method employed to ameliorate peat soil acidity and enhance nutrient availability. This study investigates the effects of liming on peat soil decomposition and subsequent CO<sub>2</sub> emissions. Liming accelerates mineralization in peat soil, thus influencing the decomposition rate. This decomposition contributes to mass loss and releases carbon dioxide (CO<sub>2</sub>) into the atmosphere. However, the interaction between liming practices, the rate of peat soil decomposition, and their impact on CO<sub>2</sub> emission dynamics is still not well understood. To address this gap, a field experiment was conducted in an oil palm plantation, applying four different liming rates (0, 2, 4, 8 tons/ha). The liming material used was Calcium Carbonate (CaCO<sub>3</sub>), applied annually over three consecutive years (2021-2023), and distributed evenly within a 2-meter radius around each oil palm. Soil CO<sub>2</sub> flux measurements were taken weekly for two years, from January 2022 to December 2023. Additionally, soil samples were collected quarterly at two depths (0-25cm and 25-50cm) to assess decomposition rates. Significant findings from this experiment include a direct correlation between liming rates and peat soil decomposition. Higher liming rates were observed to increase the decomposition rate of peat soil. The study also noted variations in CO<sub>2</sub> emissions due to liming. Based on the observed relationships among liming rates, decomposition, and CO<sub>2</sub> flux, it is recommended to optimize the use of liming materials. Continuous, long-term monitoring is suggested to track the decomposition trends, potential fluctuations, and gather more comprehensive data for informed decision-making. This would help in optimising both the operation cost and environmental sustainability of the ecosystem.

##### EVALUATION OF SOIL MICROBIAL COMMUNITIES, FUNCTIONING AND GREEN-HOUSE GAS EMISSIONS IN UNMANAGED AND DRAINED PEATLANDS IN SOUTH-WEST ICELAND

A LAGOMARSINO<sup>1</sup>, I DE MEO<sup>1</sup>, H ÓSKARSSON<sup>2</sup>, F ROCCHI<sup>1</sup>, F VITALI<sup>1</sup>, R PASTORELLI<sup>1</sup>

<sup>1</sup> CREA-AA, Firenze, ITALY

<sup>2</sup> Landbúnaðarháskóli, Reykjavík, ICELAND

The drainage of peatlands followed by land use conversion have significant impact on the fluxes of green-house gases (GHGs, i.e. CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub>O) to and from the atmosphere, driven by changes in soil properties and microbial communities.

In this study, we compared unmanaged peatlands with drained ones used as pasture or cultivated soils, common in South-West Iceland, in the frame of INTERACT program. These areas exhibit different degrees of soil water saturation and nitrogen content, following the gradient of anthropic pressure.

We assessed fluxes GHGs fluxes of the different study sites, and the impact of land conversion there on. Moreover, we investigated soil microbial community structural and functional diversity, and its connection with processes contributing to GHGs emission.

GHGs emissions resulted different between unmanaged and drained peatlands, with increased soil respiration rates (CO<sub>2</sub> emissions) and N mineralization (N<sub>2</sub>O), coherent with the trend of anthropic pressure. Drainage drastically reduced CH<sub>4</sub> emissions, but increased CO<sub>2</sub>, resulting in a higher global warming potential. Cultivation, involving occasional tillage and fertilization, further increased N<sub>2</sub>O emissions, mediated by higher N availability and conditions favorable to nitrification. Functional genes mirrored the overall trend, showing a shift from prevalent methanogenic Archaea (*mcrA*) in unmanaged, to nitrifiers (*amoA*) in drained-cultivated peatlands. Contrastingly, in unmanaged peatlands complete denitrification was prevalent, causing N<sub>2</sub>O consumption.

The soil water and nutrient content were critical factors affecting community composition in both environments, which overall affected the GHGs emissions and the relative contribution of the three gases.

**Keywords:** peatlands management, methanogenesis, nitrification, climate change, functional genes

##### SUSTAINABLE AGRICULTURAL PRACTICES USING NUTRIENT CYCLING TECHNOLOGY IN COCONUT PLANTATIONS ON TROPICAL PEATLANDS

N I FAWZI<sup>1</sup>, R NABILLAH<sup>2</sup>, F SIMANJUNTAK<sup>3</sup>, P OKTARIANI<sup>1</sup>, B SUMAWINATA<sup>1</sup>, SUWARDI<sup>1</sup>

<sup>1</sup> Department of Soil Science and Land Resources, Faculty of Agriculture, Bogor Agricultural Institute, Bogor, INDONESIA

<sup>2</sup> Tay Juhana Foundation, Jakarta, INDONESIA

<sup>3</sup> Astra Agro Lestari Tbk, Jakarta, INDONESIA

The utilization of peatlands for agriculture is pivotal for socio-economic growth but poses environmental sustainability challenges due to the ecosystem's fragility. This research evaluates the process and effectiveness of nutrient cycling management as a sustainable agricultural solution in tropical peatland coconut plantations. The study was conducted in coconut plantations in Indragiri Hilir Regency, Riau Province, Indonesia. The plantation has implemented an integrated water management system known as 'Trio Tata Air' since 1986, along with soil fertility management through nutrient cycle, primarily to support organic product market certification. The research findings indicate that the application of integrated water management and nutrient cycle systems contributes to the sustainability of peatland ecosystem. The Trio Tata Air system maintains optimal groundwater levels for plant growth and soil moisture, preventing dryness during droughts and flooding in the rainy season. The nutrient cycle in the coconut plantation, which resembles system in natural forests, eliminates the need for external synthetic fertilizer inputs. This cycle involves the natural decomposition of understory plants, predominantly the fern *Nephrolepis*, which are manually weeded every four months and left to decompose naturally. The decomposition of *Nephrolepis* provides essential nutrients for the coconut plants, equivalent to per hectare fertilizer application per four-month manual weeding cycle: P = 23.8 kg, K = 353.7 kg, Ca = 128.8 kg, Mg = 173.6 kg, and Na = 17.0 kg. This application is successfully maintaining coconut production, particularly as additional synthetic fertilizers are less effective in peat soils due to chelation and leaching. Moreover, the natural decomposition process develops organic layer about 5 cm thick above the peat soil surface, offering potential for carbon capture and storage in peatlands. By maintaining the water level and adapting nutrient cycle on the field, coconut production is higher compared to unsustainable conventional practices such as excessive synthetic fertilization, herbicide use, and burning. Thus, nutrient cycling management emerges as an effective solution for sustainable agriculture in tropical peatlands.

The Fiaavè Nature Reserve is a Natura 2000 site consisting mainly of an alkaline fen (most occurring species, *Caricion davallianae*), and includes the UNESCO World Heritage Site of the Bronze-Age pile dwellings of Fiaavè (Trentino-Alto Adige, North of Italy).

Here, a complete, 200-cm deep core (160 cm of peat plus 40 cm of underlying lake sediment) and a shallower, 50-cm core were collected in order to reconstruct the history of the most ancient European farming community, as well as the influence of past and modern agriculture on peat development.

The peat core was cut while frozen into 3-cm samples, and each of them characterized from the physical (e.g., ash, gravimetric water content) and chemical (e.g., pH, elemental analysis – CHNS -, organic matter thermal stability) point of view. Moreover, few macrofossils were identified at different depths and <sup>14</sup>C age dated, while selected subsamples were used to determine diatoms, filamentous fungi and yeasts occurrence and diversity throughout the profile.

Obtained results will be extremely useful to both support existing archaeological findings and promote the implementation of best management practices of the whole area.

##### HUMMOCK FORMATION IN ALPINE WETLANDS OF LESOTHO AND ITS IMPLICATIONS FOR SOIL CARBON BUDGET

B E MAPESHOANE, P CHATANGA, L E SELETENG-KOSE, M V MARAKE

National University of Lesotho - Botany Department, MASERU, LESOTHO

Mountains are among regions that are mostly affected by climate change because of the changing temperature and precipitation effects on soils and plant communities. Snow-cover is one of the contributing factors into the development of mountain soils because it affects soil temperature, soil moisture and length of the growing season. The depth and duration of snow-cover regulates soil temperature to ensure thermal insulation. Hence, less snow-cover may increase in the frequency and intensity of freeze-thaw cycles. These cycles do not only affect soil productivity, soil stability and erodibility, but also the soil carbon dynamics. Differences in the depth and duration of snow along the topo-sequence result in large changes in soil properties and plant communities over short distances. The freeze and thaw cycles are some of the factors that lead to the formation of microtopographic features commonly referred to as hummocks, which, are prominent features visible in many alpine wetlands' watersheds in Lesotho. These watersheds have highly productive carbon-rich soils, and the C budget illustrates that atmospheric C is sequestered through autotrophic primary production. However, changes in snow cover dynamics may directly and indirectly affect soil C dynamics and biodiversity. Data collected from Letšeng la Letsie Wetland, the only Ramsar Site in Lesotho, indicates the soil C content ranges from 3 to 9%, and hummocks have lower C concentrations than the inter hummock sites. The potential increase in average annual temperatures in the mountain regions may not only have implications for water resources but also on frequency of freeze and thaw cycles and the C budget. Long-term data are fundamental for detecting and evaluating the impact of climate change on mountain soils and for achieving a number of SDGs, in particular through SDG 15 (Life on Land) and SDG 2 (Zero Hunger), as lives of people in mountain regions depend on agriculture, which in turn depends on soil.

## 1. Equity, diversity, and inclusivity in soil sciences 1.04 133511 - Moving toward Diversity, Equity, and Inclusivity in Soil Science Societies

### ANALYSIS OF RACIAL AND ETHNIC DIVERSITY WITHIN THE SOIL SCIENCE SOCIETY OF AMERICA

H. GOLLANY <sup>1</sup>, S. DAROUB <sup>2</sup>, A. DAIGH <sup>3</sup>, C. WILLIAMS <sup>4</sup>, G. JHA <sup>5</sup>, C. OLADOYE <sup>6</sup>, C. OLSON <sup>7</sup>, H. VAN MIEGROET <sup>8</sup>, S. CHAPMAN <sup>9</sup>, B. HACQUES <sup>10</sup>

<sup>1</sup> United States Department of Agriculture, Adams, USA

<sup>2</sup> University of Florida, Gainesville, USA

<sup>3</sup> University of Nebraska-Lincoln, Lincoln, USA

<sup>4</sup> USDA-Natural Resources Conservation Service, Lincoln, USA

<sup>5</sup> Kansas State University, Manhattan, USA

<sup>6</sup> Clemson University, Blackville, USA

<sup>7</sup> United States Geological Survey, Reston, USA

<sup>8</sup> Utah State University, Logan, USA

<sup>9</sup> Soil Science Society of America-Headquarters, Madison, USA

<sup>10</sup> Soil Science Society of America-Headquarters, Madison, USA

The Soil Science Society of America (SSSA) Inclusivity Assessment Committee analyzed racial and ethnic members' diversity based on optional self-reported data. Despite comprising less than 67% of total SSSA members, self-reporting varied significantly across membership levels. Senior members exhibited the highest self-reporting at 98%, while students, constituting approximately 30% of the membership, reported only 22%. The limited self-reporting by students hinders a comprehensive analysis of trends over time, but insights from an earlier gender report suggest students represent the most diverse cohort. Emeriti members displayed the least racial and ethnic diversity, with 93% identifying as Caucasian White and less than 6% as BIPOC (black, indigenous, and people of color). Among active members, around 60% identified as Caucasian White, with BIPOC representation ranging from 12% (2015-2019) to 14% (2020). Graduate student retention data indicated that only 10% transitioned to full professional membership after 7 years, with a consistent 50% attrition rate in the second year for new graduate students, despite active participation in the annual meetings. Scholarships predominantly benefit younger members (students and early career), influencing their perceptions of the commitment to ethnic diversity and their decision to stay active. To address these findings, SSSA aims to actively increase engagement of students and early career members in including mentoring programs and society governance for example serving on committees. . This proactive involvement is crucial for retaining these young members, who represent the foundation of future demographic trends within the SSSA, ensuring continued vitality and diversity.

## 2. Soil and humanity 2.03 129617 - Soil Health from Multiple Perspectives

### HARMONY BENEATH OUR STRUCTURES: BRIDGING SUSTAINABLE ARCHITECTURE AND SOIL SCIENCE IN A CHANGING WORLD

N. HATAMLEH

Kansas State University, MANHATTAN, USA

This presentation aims to explore the integration of sustainable architecture with soil science from an architectural perspective, placing a spotlight on the critical significance of soil health in shaping the future of architectural practices. Delving into the intersection of these disciplines, the proposal emphasizes the role of soil as a foundation for natural construction materials, promoting an eco-centric approach to building design.

Environmental art takes center stage as a catalyst for inspiration and innovation in this presentation. By combining the aesthetic aspects of environmental art with the precision of science, the proposal envisions architecture as a harmonious synthesis of creativity and technical expertise. The focus extends to the transformative potential of soil as a sustainable resource for construction materials such as brick and cement, challenging conventional paradigms and advocating for a shift towards eco-friendly building practices.

The presentation sheds light on the intrinsic relationship between soil health and architectural sustainability. It highlights the interconnectedness between the built environment and the natural world, underscoring the pivotal role of soil microorganisms in fostering a healthy and resilient foundation. The proposal advocates for a holistic approach that not only minimizes environmental impact but also elevates the overall well-being of ecosystems through sustainable architectural principles and advancements in soil science.

By exploring soil as a foundation for natural construction materials and setting Middle Eastern practices as an example, this presentation aims to inspire innovative design strategies that prioritize ecological balance. It envisions a symbiotic relationship between human-made structures and the earth, emphasizing the potential for sustainable architecture to be a transformative force. As we navigate an era where environmental consciousness is paramount, this proposal invites a reimagining of architecture as a dynamic discipline deeply rooted in the principles of integrating arts and sciences within the application of soil considerations.

### ROOTED – SOIL HEALTH AND MEMORY OF PLACE.

S. JORDA <sup>1</sup>, R. JANKE <sup>2</sup>, P. WATTS <sup>1</sup>

<sup>1</sup> Ecoartspace, Santa Fe, USA

<sup>2</sup> Kansas State University Dept. of Horticulture, Manhattan, USA

When you extract a plant from the soil, the network of roots reveals a cartography of growth and entangled complexity within the soil. As an artist, this cartography is a rich visual field to draw upon and interpret. Collaborating with soil scientists, additional layers of unseen information – revealed through DNA mapping of soil bacteria, archaea, and fungi – have provided opportunities for fruitful artist/scientist cross-disciplinary interaction. One example of this is the “Rooted” project, which compares the embedded information of the unseen soil microbes to the idea of memory – specifically to connotations of homeland and the uprootedness of the immigrant experience.

Just as the DNA mapping of soil microbes can reveal unseen characteristics of soil, the immigrant experience is one where the memories of one’s homeland become an invisible layer beneath new lived experiences. This correlation is linguistically notable in Spanish, whereby the word soil translates to tierra, with rich connotations such as “mi Tierra,” meaning “my homeland,” or more literally, “my soil.” Carrying this linguistic connection forward in my own art practice, the “Rooted” project ties together research on soil health with narratives of immigration, assimilation, and identity.

To determine the microbial profile of two specific locations, the Sonoran Desert and the Desert Upland in Arizona (USA), I buried cotton cloths at these sites for one to two months. Soil samples from these two sites were also sent to a lab for analysis. The unearthed cloth along with the lab analysis serve as a visual device to interpret the differing microbial profiles, and inform “Rooted.” The cloth, embroidered and shaped into a pair of slip-on shoes, interpret the idea of “second skin” to explore memory of place and the soil.

### THE POPULARIZATION OF SOIL SCIENCE IN BRAZILIAN CHILDREN'S AND YOUNG ADULT LITERATURE BOOKS

J.G.R. OLIVEIRA<sup>1</sup>, A. ..A. RIBON<sup>2</sup>, E. ..D. ..R. . DUARTE<sup>3</sup>, L. ..O. RIBEIRO<sup>4</sup>

<sup>1</sup> Universidade Estadual do Norte do Paraná, CORNÉLIO PROCÓPIO, BRAZIL

<sup>2</sup> Universidade Estadual de Goiás-Unidade Universitária de Palmeiras de Goiás., Palmeiras de Goiás., BRAZIL

<sup>3</sup> Universidade Federal de Roraima, Boa Vista, BRAZIL

<sup>4</sup> Universidade Estadual de Londrina., Londrina, BRAZIL

The popularization of Soil Science is committed to communicating, disseminating, and recontextualizing scientific knowledge related to soil to society at large. In this context, This summary aims to present Brazilian children's and young adult literature books used for the popularization of Soil Science. In Brazil, soil professionals or researchers have published children's and young adult literature books with soil as their main theme. The "Solo na Escola UENP" (Soil in Schools), an extension project from Statual University of Paraná (UENP), in the State of Paraná, South region of Brazil, has excelled in producing and publishing children's and Young adult books that focus on soil, such as: "Soil Biodiversity: A World Beneath Our Feet" the book presents the biodiversity found in the soil, listing the soil's megafauna, macrofauna, mesofauna, and microfauna along with their functionalities within the system. Additionally, it showcases activities that lead to degradation of life in the soil and actions that can aid in soil recovery and conservation. The books "What is Soil For?", "Little Red's Birthday", and "A Special Picnic on World Soil Day" address the functions of soil in the environment, specifically portraying the soil's function as a producer of food, fibers, and fuels. The books "Little Clod is Feeling Sick", "Where Did the Water Go?" and "A New Soil for Ant Betty" depict soil degradation and present some alternatives for soil recovery. The books are used in Soil Science popularization efforts in both formal and informal educational contexts, combined with playful activities such as storytelling, theater and animations. It is believed that children's and young adult literature books can be a powerful tool to increase awareness of the value of soil in society, particularly in popularizing Soil Science. These materials are characterized by simple, didactic, and illustrative language; they inform society about various soil-related topics; enhance human perception of soil, and ultimately, recontextualize scientific discourse with texts aimed at layreaders.

**SOIL IS NOT A LAYER: URBAN PLANNING AND SOIL KNOWLEDGE**

S. DENIZEN

Washington University in Saint Louis, Saint Louis, USA

Soil often plays a key role in landscape planning. However, there are some key limitations to conventional approaches for incorporating soil data into planning models. The separation of soil and land-use layers in conventional planning maps has led to a systemic misunderstanding of the complex socio-ecological relationships that drive processes like land degradation and climate change induced migration. Failed conceptual models for how to imagine the relationship between soils and human environments should lead us to reconsider the way soils are made an object of planning in the 21st century.

#### GET TO KNOW THE SOIL WITH DASY: EXPERIENCES OF USING A COLORING BOOK TO EDUCATE CHILDREN ABOUT SOIL.

C. SIEBE <sup>1</sup>, A. ALVARADO <sup>2</sup>, A.C. LOPERA GASCA <sup>1</sup>

<sup>1</sup> Universidad Nacional Autónoma de México, Institute of Geology, Ciudad de México, MEXICO

<sup>2</sup> Universidad Nacional Autónoma de México, Dirección General de Divulgación de la Ciencia, Ciudad de México, MEXICO

Soil is an essential resource for life on Earth. It sustains plants, which in turn provide food and oxygen for animals and humans. Soil also plays an important role in the water cycle and air quality. It is therefore important to educate children about the importance of soil and the main degradation processes. In this way, children can learn to appreciate soil and take action to protect it. This is why we joined the efforts of the IUSS International Decade of Soils 2015-2024 (IDS) by developing an interactive coloring book for school-age children and young adults.

The coloring book *Get to know the soil with Dasy* is an effective tool for educating children about soil. The book is written in simple Spanish and addresses key soil education topics such as the importance of soil, soil biodiversity, the connection between soil and human health, threats to soil, and soil conservation. The book is illustrated with graphics that attract children's attention and help children understand complex soil concepts. In its final page, it invites the children to either paint, or write about the soil and its importance in their immediate surroundings, and to send the outcome to the outreach program *Terramóvil* of the Institute of Geology. In the conference we will provide examples of how the coloring book has been used in some schools from primary to secondary level. The experience has been very positive. Children who have used the book have shown a greater interest and understanding of the importance of soil. They have also been more likely to participate in soil conservation activities such as planting trees, composting and reducing waste.

The book can be complemented by school teachers with a set of hands-on activities provided by the outreach program *Terramóvil*. These can be downloaded from the web site or implemented at the school yard by trained bachelor students from the Earth Sciences School of the National University of Mexico.

<sup>3</sup> Agronomy Institute, Department of Soils, UFRRJ, Rio de Janeiro, BRAZIL

The Soil Education for All Project at the State University of Goiás, Palmeiras de Goiás campus, in Brazil, involves many activities to facilitate the understanding of complex topics for Basic Education, including the use of characters illustrating soil profiles, their main characteristics and pedogenesis (<https://aaribon.wixsite.com/educacao-em-solos/perfis-de-solos-divertos>). The project, called Fun Soil Profiles, started with 13 orders of soils, according to the Brazilian Soil Classification System (SiBCS), as a teaching material to support education related to the soil sciences, aiming at building the concept of soil taxonomy. In the material developed according to SiBCS, the characters were publicized on the social networks of the Soil Education Project for All and on the Extension Project website and at various events, since 2020, in workshops, festivals, lectures and other activities with different audiences, in virtual and in-person format. In this present work, the profiles were adapted to illustrate the 12 soil orders according to Soil Taxonomy: Alfisols, Andisols, Aridisols, Entisols, Gelisols, Histosols, Inceptisols, Mollisols, Oxisols, Spodosols, Ultisols and Vertisols. This system was chosen because it is one of the international soil classification systems and because it has a smaller number of classes at its highest taxonomic level, simplifying its representation. The result will be published as an illustrated book for children, translated into several languages, which will be presented at the event. The book addresses each character in a simple and playful way, according to their most defining characteristic and choosing aspects related to their genesis and the environment where these soil classes predominate, which makes the understanding of this concept easier and more enjoyable for children.

<sup>2</sup> Institute for Sustainable Plant Protection of National Research Council, Portici, ITALY

<sup>3</sup> University of Naples Federico II, Department of Mathematics and Applications R. Caccioppoli, Napoli, ITALY

Understanding the importance of microbiota in the agronomic field has led to an increasing number of studies aimed at exploring ways to modulate and support a healthy microbial community for overall plant health and disease prevention. In agriculture, researchers are focusing on the soil microbiota's role in promoting plant growth, soil fertility and maintaining the health of agricultural ecosystems. Our work aims to find a correlation between the microbiota composition of the soil and its functional diversity under different farming systems, determining the optimal composition to ensure biological soil fertility. The treatments considered for the present study are three: i) organic cultivation with the use of biofertilizers; ii) cultivation under integrated pest management; and iii) cultivation under a conventional farm regime (control). Soil samples collected from different treatments were analyzed to study the composition of the microbiota community by sequencing 16S and ITS amplicons for bacteria and fungi, respectively. At the same time, soil samples were analyzed with Biolog® EcoPlates to evaluate the functional diversity of microbiological communities by measuring their ability to use different carbon sources. All the collected data will be used to train machine learning algorithms to develop a model able to produce indices of soil fertility and forecast the state of health of soils. It is important to implement a continuous monitoring system to gather fresh data to re-train and improve existing ML models and to ensure the model's accuracy. Once the model has proven to be accurate, it can be implemented to predict soil fertility. Here we represent preliminary results and the ML algorithm we intend to employ. However, it is important to note that the results will depend on the quality of the data used during the training and the accurate understanding of the relationships between soil microbial composition and soil fertility. The application of Artificial Intelligence could help farmers in optimizing resource use, improving soil management and sustainably, and increasing agricultural productivity.

<sup>2</sup> Basalti Orvieto srl-Loc. Cornale, Castel Viscardo, ITALY

Lactic Acid Bacteria (LAB) have GRAS (Generally Recognized as Safe) status by the Food and Drug Administration. They are safe for human and animal consumption and now have become ideal for commercial development in food and environmental application. To date LAB are a promising candidate for sustainable agriculture and there are some recent evidences that LAB-based composting materials are well suitable also for alkaline soils. Moreover LAB are halotolerant and survive at high salinity conditions in the dry environments.

Considering that the combined application of powdered rocks and microbial inoculants has been proved to be a good strategy to restore microbial diversity and activity in disturbed soils, the aim of this research was to evaluate the effectiveness of "LAB coformulation" in oligotrophic Technosols bacterization in presence and/or absence of cover crop. Specifically "bioactive basalt flour" combined with LAB, yeast and microbial consortia, from compost, was applied as "spray treatment" to basaltic-carbonate dismissed quarries in order to assess taxonomic shifts in soil microbiome.

At Cornale experimental field (near Terni, Italy) the "LAB coformulation" was applied four times during the year 2020 (in the winter and in the spring). At July (2020) soil sampling was performed and taxonomic composition were analyzed by rRNA 16 S amplicon sequencing with NGS (Next Generation Sequencing – Illumina). In addition, the microbiological evolution of r-K-strategist spectrum was assessed. The r-K spectrum confirmed the oligotrophic traits of microbial consortia well adapted to environmental condition of quarries. NGS data for July track LAB establishment in both soils inoculated (with and without cover crop) even if the sequences assigned to LAB occurred as "rare". Amplicon Sequence Variants (ASV) highlight the evolution of microbial resilience for plots inoculated and the results showed that trophic index (Proteobacteria: Acidobacteria ratio) was positively affected. Moreover in the inoculated plots the Actinobacteria, as copiotrophs, increase with decreasing the abundance of some oligotrophs such as many member of Acidobacteria.

#### EFFECT OF SOIL WATER EROSION CONTROL AGRO-TECHNOLOGIES ON SOIL WATER SAVING UNDER WINTER WHEAT-MAIZE ROTATION ON EPICALCIC CHERNOZEM

M KERCHEVA<sup>1</sup>, G KUNCHEVA<sup>1</sup>, V KOLCHAKOV<sup>1</sup>, M MITOVA<sup>1</sup>, M IVANOVA<sup>1</sup>, I IVANOVA<sup>2</sup>

<sup>1</sup> ISSAPP N.Poushkarov, SOFIA, BULGARIA

<sup>2</sup> IASS Obratsov Chiflik, Ruse, BULGARIA

Contour tillage, minimum tillage, cover crops and green manure are widely accepted as agro-technologies for soil water erosion control. The aim of the current study was to compare the efficiency of water erosion control technologies for water saving under maize and winter wheat rotation on moderately eroded Epicalcic Chernozem in the region of Ruse, North Bulgaria. The field experiment was performed on sloped terrain from 2021 till 2023 year under wheat and maize in rotation at up-and-down slope tillage (T0), traditional contour tillage (T1) and crop specific erosion control contour tillage (T2). The T2 variant includes minimum tillage, direct sowing and use of cover crop after wheat harvest which is incorporated in the soil as green manure before maize sowing. The seasonal variations of reference evapotranspiration (ET<sub>o</sub>), precipitation and heavy precipitation events during the studied years were determined and statistically evaluated based on long term (1961-2023) meteorological records. Based on calculated drought indices (SPI, PDSI) it was found that severe drought occurred in 2022 and 2023. The obtained experimental data for soil moisture and run-off were used for assessing the effective precipitation and water saving effect of the studied variants. The water run-off (April-September) under winter wheat and maize was reduced by 25 and 28% in T1 and by 35 and 39% in T2, correspondingly. Cover crops decreased soil water storage in spring more pronouncedly when a single cover crop was grown in the drier and warmer 2022 (-7%) and 2023 (-13%) than when a mixture of crops was grown in wetter 2021. In the mid-season of maize the difference in soil water storage under the studied variants increased in moderately dry conditions while there was no difference in very dry years. The temporal and spatial scales of soil water balance estimates under studied variants were extended by applying simulations with Wofost, WinSareg and SWAT models.

#### MULTIPLE STRESSORS (PESTICIDE, COPPER, WASTEWATER) MIGHT CHANGE AT LOW DOSES ABUNDANCE AND FUNCTION OF SOIL MICROORGANISMS IN CITRUS ORCHARDS

D PAMPINELLA<sup>1</sup>, F STACHE<sup>2</sup>, V A LAUDICINA<sup>1</sup>, L BADALUCCO<sup>1</sup>, F DITTERICH<sup>2</sup>, C POLL<sup>2</sup>, E KANDELER<sup>2</sup>

<sup>2</sup> University of Hohenheim, Institute of Soil Science and Land Evaluation, Stuttgart, GERMANIA

Soil microbial community directly affect nutrient cycling through organic matter turnover. However, such a role of soil microorganisms is highly dependent on their resilience to environmental stress. Understanding the link between environmental factors and the activity of microbial community is essential for sustainable land management practices. Soil microbial community is considered highly sensitive to soil environmental changes, and the exposure to multiple stressors, even at low doses, could induce harmful effects on soil microorganisms. Citrus wastewaters (CWWs) have been proposed to be used for crop irrigation thus promoting the circular economy approach. However, due to their high content of organic compounds, such as organic acids, and low pH, it is necessary to understand their interaction with other environmental stressors such as copper and pesticides. Copper and abamectin are commonly used as a fungicide and as insecticide, respectively, in citrus orchards.

This study focuses on the impacts of copper and abamectin on microbial community structure and activity of soil moistened with CWWs. To investigate the effect of such factors on soil microbial community and activity, a lab-scale experiment was set up. The experiment lasted 56-days.

The soil was pre-incubated for 14-days and moistened with distilled water at 35% of maximum water-holding capacity (WHC). Eight different treatments were set up to investigate the effects of three stressing factors (2.2 mg kg<sup>-1</sup> of copper, 0.012 mg kg<sup>-1</sup> of abamectin and CWWs), individually and in combination at a maximum WHC of 40%. Soil moistened only with distilled water was used as a control.

During the experiment, microbial biomass C and N (MBC, MBN), microbial community structure (qPCR) and activity (soil respiration and enzymes activities) were assessed. Preliminary findings suggest that treatments involving CWWs led to an increase in soil respiration, probably due to the introduction of organic matter and soil inorganic carbon solubilization.

### 2.14 133604 - Histories of internationalization of soil science

#### SOIL CLASSIFICATION IN THE EAST AFRICAN SOIL MAP (1936) AND ZAMBIA'S ECOLOGICAL SURVEY: CONVERGENCES AND CONTRASTS

M. LARK<sup>1</sup>, I. MUKUMBUTA<sup>2</sup>, N.L. NAMWANYI<sup>2</sup>, S. SICHINGA<sup>3</sup>, L.M. CHABALA<sup>2</sup>

<sup>1</sup> University of Nottingham, Nottingham, UNITED KINGDOM

<sup>2</sup> University of Zambia, Lusaka, ZAMBIA

<sup>3</sup> Soil Survey Unit, Zambia Agriculture Research Institute, Chilanga, ZAMBIA

The production of continental-scale soil maps was an early ambition of the IUSS. This required classifications which could be used internationally. An early soil classifications for Africa was presented by Shantz and Marbut, based on Dokuchayevian principles, but this was found wanting by those scientists tasked with producing a map for what was then British East Africa.

In developing the soil classification used in the East African Soil Map, Milne et al. (1936) can be seen wrestling with the outlines of an emerging theory of factors of soil formation, which Jenny would later formalize. In particular they recognized how topographic and geological factors are expressed in soil variation, which is not just a factor of climate. We can also see them distinguishing between the problem of how to classify soil in genetic terms, and how to predict which soils might be found at unsampled sites. Trapnell, from Zambia, then Northern Rhodesia, was involved in the margins of this process, corresponding with Milne and contributing to the proceedings of the Second Meeting of East African Soil Scientists which took place in Zanzibar in 1934 (although penny-pinching by the Government in Livingstone prevented his participation in person).

We argue that Trapnell influenced the final legend of the East African Map more than has been generally recognized (particularly in the adoption of the Plateau Soil class), and that the environmental variation of Zambia at different scales required him to develop a conceptual model of soil variation which was, in some ways more sophisticated than the one embedded in the East African map. We suggest that this early experience highlights the importance of local soil classifications, and of preserving information based on local classification from early 20th-century surveys.

<sup>2</sup> INSTITUTO NACIONAL DE INVESTIGACIONES FORESTALES, AGRÍCOLAS Y PECUARIAS, TOLUCA, MEXICO

Within the framework of the celebration of Soil Day in the year 2020, in Mexico, we inaugurated the first and unique National Soils Museum. It has 60 exemplars monoliths which were recollected by students and professors of Postgraduate of Edaphology, in the Postgraduate Colege with other institutions of several places of the country. The objective is to make known different activities, for example, diffusion and capacitation of soil properties, laboratory analysis, monolith making, and soil classification, among others. Courses and talks are aimed at undergraduate and graduate students, farmers, and the general public. We visit scientific fairs at Universities and Congresses. Also, in the year 2022, we making the first Monolith Collections with agricultural and economic importance to scale statal and regional. The first one is a collection of Mexico State, it has 14 exemplars for a surface of 22 500 km which is localized in the Museum; while the second one, is from the municipality of Temascalcingo, Mexico State, which it has 7 monolith exemplars for a surface of 362.39 km and it localized in the facilities of the culture house of the same municipality, that it can be consulted by farmers. With the several activities of the Museum, we aim to raise public awareness about the importance of soil conservation, their diversity, and the wide range of ecosystem services that they provide us.

**SOIL HEALTH PARAMETERS IN VARIOUSLY POLLUTED SITES IN HISTORICAL SZCZYTNICKI PARK IN WROCLAW**

A. KARCZEWSKA<sup>1</sup>, A. DRADRACH<sup>2</sup>, K. LEWINSKA<sup>3</sup>

<sup>1</sup> Wroclaw University of Environmental and Life Sciences, Inst. of Soil Science, Plant Nutrition and Environ. Protection, Wroclaw, POLAND

<sup>2</sup> Wroclaw University of Environmental and Life Sciences, Institute of Agroecology and Plant Production, Wroclaw, POLAND

<sup>3</sup> Adam Mickiewicz University in Poznan, Department of Soil Science and Remote Sensing of Soils, Poznan, POLAND

Soils of urban green areas, including parks, forests, lawns and other spaces covered by vegetation, constitute a valuable pool of natural resources in cities, providing various ecosystem services. Therefore, it is important to maintain such soils in good health. Creating urban green areas was usually preceded by land leveling that used various materials, including construction wastes, rubble, sediments from dredging lakes and rivers, industrial ashes, etc., which become soil parent rocks. Waste organic materials are often applied to such soils, for instance composts and sewage sludge, often rich in heavy metals and other pollutants.

The aim of the study was to assess soil health, visual characteristics of vegetation and its chemical composition in variously polluted parts of Szczytnicki park, the largest park in Wroclaw. Previous screening indicated some areas in this park with soils enriched with heavy metals. Present research was carried out in two parts of the park: 1) with high concentrations of heavy metals (up to 800 mg/kg Cu, 1400 mg/kg Zn, 290 mg/kg Pb and 10.5 mg/kg Cd), exceeding the levels legally considered safe, and 2) in unpolluted part of the park. In each part, two lawns were chosen where analyses were performed in four replicates. Field work involved characteristics of habitats, composition of vegetation and its visual assessment, measurements of soil respiration (several times a season). Soil features analyzed in the laboratory included pH, heavy metal concentrations, fertility, microbiome composition and enzymatic activity. Additionally, plant samples were subject to chemical analysis.

The research showed that most of soil health indices did not differ significantly between two parts of the park. Their variance within the parts was greater than the differences between them. Plant uptake of toxic elements turned out not to be a serious problem. This confirms that maintaining soil conditions appropriate for phytostabilization, including pH, allows for the safe use of urban green areas despite the presence of high concentrations of potentially toxic metals.

**EX-SITU VITRIFICATION AS REMEDIATION ALTERNATIVE FOR URBAN CONTAMINATED SOILS OF BARCELONA (CATALONIA, SPAIN)**

S. URBANEJA <sup>1</sup>, M. GARCIA-VALLES <sup>2</sup>, P. ALFONSO <sup>3</sup>, N. ROCA <sup>1</sup>

<sup>1</sup> Dept. BECCA, Facultat de Biologia. Universitat de Barcelona., Barcelona, SPAIN

<sup>2</sup> Dept. de Mineralogia, Petrologia i Geologia Aplicada. Universitat de Barcelona, Barcelona, SPAIN

<sup>3</sup> Dept. de Enginyeria Minera, Industrial i TIC, Universitat Politècnica de Catalunya, Manresa, SPAIN

The vitrification technology is one of the most promising alternative methods for the immobilization of heavy metals contained into polluted soils. Soils contaminated with heavy metals may have application in industry to produce glasses and glass-ceramics. Therefore, the objective of this study was to assess the viability of ex-situ vitrification as remediation strategies for contaminated urban soils of Clot neighbourhood (Barcelona, Spain). The studied polluted urban soil shows a basic pH and low organic carbon contents. Sandy-loam and clay loam texture classes are observed in the topsoil and subsoil, respectively. The most contaminated horizon of the studied soil has quartz 30%, illite 40%, clinochlore 4%, potassium feldspar 5% and plagioclase 18%. The calcite content is relatively low (4%). The main pollutants in this soil are Cd, Pb and Zn with 4.36, 154.42 and 256.77 mg·kg<sup>-1</sup>, respectively. Glass was formulated using 85 wt% of soil and 15 wt% of Na<sub>2</sub>CO<sub>3</sub>. The density of the glass is 2.50 g/cm<sup>3</sup>, similar to silica and soda-lime glass. The expansion coefficient of the glass is 10.6·10<sup>-6</sup> °C<sup>-1</sup> due to the Al<sub>2</sub>O<sub>3</sub> content of the clay horizon. The chromatic coordinates are L 43.46, a 0.37, b 1.12, C 1.18, and H 71.72. Two thermal treatments have been carried out on and analysed by XRD, in order to know which mineral phases would be generated. The evolution of the glass reflects the presence of a single very wide exothermic event at 825 °C and an endothermic one at 1125 °C. At 790 °C there is still no crystalline phase. The glass treated at 950 °C has two crystalline phases, diopside and wollastonite. The start temperature formation was 825 °C according to the ATD. Viscosity-temperature curve was used to calculate the relevant temperatures for the process. The contents of the elements leached from the glass are well below the limits established by European legislation. Thus, the vitrification is an effective remediation technique for these contaminated soils.

**LABORATORY EXPERIMENT ON UNDISTURBED MESOCOSMS: THE LEACHING OF HEAVY METALS FROM CONTAMINATED SOIL**

D. ABU EL KHAIR, C. FERRÉ, R. COMOLLI

University of Milano-Bicocca - Department of Earth and Environmental Sciences, Milan, ITALY

One of the most important ecosystem services provided by soil is its ability to slow down and mitigate the percolation of pollutants, of natural or anthropogenic origin, into aquifers, a function of great importance for maintaining good groundwater quality.

This study is part of the PNRR project (Biodiversity Future Center, Spoke 5: Urban Biodiversity) and aims to assess the leaching of heavy metals (Cr, Cu, Ni, Pb, and Zn) under controlled laboratory conditions.

The experiment used undisturbed soil columns (mesocosms) of Ap and Bw horizons of a Dystric Cambisol, with bulk densities of 1.07 and 1.68 g/cm<sup>3</sup> respectively, constructed manually by assembling PVC tubes (diameter 14 cm) to create 40 cm long cylinders with a 5 cm drainage layer. Both horizons are characterized by a strong acidic reaction (pH 4.7 and 5.3 respectively), a good content of organic C (Ap: 2.34%; Bw: 1.07%), and a silt loam texture. They also have a high content of heavy metals (topsoil - Cu: 161 ppm; Pb: 214 ppm; subsoil - Cu: 64 ppm; Pb: 45 ppm).

In order to evaluate the leaching of metals under controlled conditions, an extreme meteorological event for the Milan Region (150 mm of precipitation in one day) was simulated, stressing the system while maintaining a constant head of 10 mm and collecting the percolated water every hour.

Preliminary data show that water infiltrates relatively easily into the topsoil (9.8 mm/h), leaching a small fraction of the exchangeable and soluble fraction of metals present in the Ap horizon (Cr: 1.17%; Cu: 1.10%; Ni: 1.55%; Pb: 0.09%; Zn: 0.18%). In the subsoil, however, water tends to infiltrate much more slowly (0.4 mm/h).

The results were used as a basis for a long-term monitoring period (6 months), during which the leaching of heavy metals was assessed in both the topsoil and subsoil, replicating a spring-summer precipitation cycle.

### DETERMINATION AND ASSESSMENT OF POLYCYCLIC AROMATIC HYDROCARBONS IN SOILS OF A MEDITERRANEAN AREA

R. BOLUDA HERNÁNDEZ <sup>1</sup>, E. FERNÁNDEZ-GÓMEZ <sup>1</sup>, L. ROCA-PÉREZ <sup>1</sup>, O. ANDREU-SÁNCHEZ <sup>1</sup>, G. BLANCATO <sup>1</sup>, M. GAMÓN <sup>1</sup>, J.A. RODRÍGUEZ-MARTÍN <sup>2</sup>

<sup>1</sup> UNIVERSITY OF VALENCIA, Burjassot, SPAIN

<sup>2</sup> INIA-CSIC, Madrid, SPAIN

Soil pollution represents a global problem, which is increased by various human activities, such as, industrial activity, inappropriate agricultural practices, tourism, as well as urbanisation. Organic soil pollutants resulting from anthropogenic activities include the polycyclic aromatic hydrocarbons (PAHs), that stand out for their persistence, toxicity, and mobility in the environment. PAHs are a group of organic compounds with two or more aromatic rings, originating from both natural and anthropogenic sources. The latter include industrial activities, waste and biomass incineration, as well as emissions from vehicles. Therefore, soil analysis is an essential environmental and public health challenge, where preserving the health of soils is crucial to promote the sustainable development goals and meet the 2030 agenda. The objective of this work was to determine and assess the presence of 13 PAHs in urban, industrial and agricultural soils. Several field campaigns were carried out, where soil samples were collected in 59 sites from 17 municipalities in l'Horta and La Ribera de Valencia (Spain). An extraction was carried out using the QuEChERS multiresidue method and quantification of the compounds by GC-MS/MS. The results obtained showed that the total PAHs content ranged between 506.3 and 5.1 microg/kg. The high molecular weight PAHs (HMWPAHs, PAHs with 4-6 aromatic rings), predominated over low molecular weight PAHs (LMWPAHs, PAHs with 2-3 rings). LMWPAHs/HMWPAHs ratio in the studied soils indicated that the main source of contamination is of pyrogenic origin. The results also showed a correlation among total PAHs content with population density and vehicles number.

<sup>1</sup> Consiglio per la ricerca in agricoltura e la analisi della economia agraria, Firenze, ITALY

<sup>2</sup> Consiglio Nazionale per le Ricerche, Firenze, ITALY

<sup>3</sup> Institut national de recherche pour la agriculture, la alimentation et le environnement, Paris, FRANCE

<sup>4</sup> Wageningen University & Research, Wageningen, THE NETHERLANDS

The objective of the work package 6 of the EJP SOIL programme (<https://ejpsoil.eu/>) is to support soil data sharing in Europe, which implies overcoming legal constrains. An analysis of the EU legal framework on soil data sharing was performed, and a questionnaire on soil data ownership and sharing was elaborated and distributed among EJP SOIL partners, and, through them, to relevant stakeholders, external to the consortium. A deliverable (D6.2), in the form of a public report (<https://doi.org/10.5281/zenodo.10014912>), was elaborated, which consists of an introduction to EU legal framework, an analysis of questionnaire results, and a general agreement for soil data sharing. The response to the questionnaire and the elaboration of the soil data sharing agreement involved the contribution from 62 authors, 32 institutions, of 22 European countries. The questionnaire showed the lack of specific national transpositional laws in relation to the sharing of soil information, the lack of officially appointed soil officers and, the lack of networking between the soil data owners/holders and the public institutions officially appointed for the INSPIRE (Soil) implementation. A conflict of interests between public and private rights was evidenced, and the D6.2 final agreement suggests 6 general best practices to overcome these constraints in order to get the consent from landowners for the open disclosure of point georeferenced soil data, with the only exception given by the data on emissions of pollutants into the environment, to respect the intellectual property rights of authors, and/or an economic payment in case of soil maps.

## 3. Soil governance

### 3.08 133775 - Soil governance: building on stake-holders interactions and involvement for a sustainable management of soils

#### SHAPING FUTURE SOIL GOVERNANCE - THE NEED FOR WIDESPREAD PARTICIPATION

G. ROCCHEGIANI, N. RODRÌGUEZ EUGENIO

Food and Agriculture Organization of the United Nations - Global Soil Partnership (GSP), Rome, ITALY

Soil governance is a cross-cutting issue that needs to be addressed at the highest level. Soils serve as the basis for several uses, from agriculture and forestry to urban development, industry, and mining. Regulating the protection and the sustainable use of soil is therefore a complex operation, as it must address all possible land uses, ensure the preservation of the multitude of ecosystem services soil provides, and involve the plethora of stakeholders dealing with its management. The simultaneous presence of multiple points of view requires the participation of the maximum number of stakeholders at early stages. Since its creation in 2012, the Global Soil Partnership has become a global forum where global soil issues are discussed and addressed by multiple stakeholders. To support FAO Members in strengthening or developing their normative frameworks on soils, the GSP is developing a legal guide on sustainable soil management that includes the main principles to be included in any law on sustainable soil management and protection, including the participatory principle. This principle of participation responds to different needs: from social justice according to which it is necessary that everyone, especially those who have to do with the object to be regulated, can make their voice heard leaving no one behind. Being able to synthesize the numerous and conflicting demands of individuals to avoid regulatory vacuums and antinomies must be seen as a great opportunity. This principle of participation when applied to civil society would first and foremost succeed in increasing the existing awareness around soil and its protection. Involving citizens in policymaking helps them feel ownership and follow its dictates, as they have contributed to its definition and such imposition will be viewed more favourably. This contribution aims to present the work of the GSP on soil governance and to engage participants in reviewing and agreeing on the principles to be included in FAO's legal guide for sustainable soil management.

In response to the observation of a dispersion of the scientific and technical expertise and initiatives on French soils, the French Ministry in charge of Agriculture launched the French network of scientific and technical expertise on soils (RNEST) in December 2016.

The network aims to federate French research, development, and innovation (RDI) stakeholders, working on soils (forest, agricultural, urban, industrial fallow land, contaminated sites, natural areas, etc.).

Its main mission is to strengthen the scientific and technical expertise and initiatives on soils to guide public policies, and to answer to the needs of stakeholders concerned by soil management.

The network is supported by organisations representing national soil RDI key players: the French ministries in charge of agriculture, environment, and higher education and research, which co-lead the network, three national agencies, a research institute, a research alliance, a learned society, and two agricultural organisations.

The RNEST also relies on a scientific, technical and innovation committee, composed of 32 experts with varied and complementary expertise profiles (pedology, economics, biogeochemistry, etc.), and diverse sectors of activity (academic research, consultancy firm, local authority, association, etc.). This committee carries out actions related to the field of public policy, RDI, and diffusion of information on soils.

Since its launch, the network has enabled its members to carry out actions to provide and facilitate access to expertise for decision makers, and to foster interactions between soil RDI stakeholders.

We intend to present this organisation, share feedback and perspective on how such a multi-stakeholder hub can operate, and illustrate this with two examples. The first one will show how the hub could mobilise to provide input on recent EU and French law proposals on soils. The second one will highlight an original work of the hub that draw up an approach to compare different types of soil degradation, as a first step to allow stakeholders to develop a global and shared vision of the concept of soil degradation.

## 4. Soil health in achieving the Sustainable Development Goals 4.02 124990 - Towards harmonized soil health monitoring. Novel methods and perspectives and scientific, institutional, and societal challenges

### RELATIONSHIP BETWEEN CS-137 AND SOIL ORGANIC CARBON (SOC) IN AN ARABLE HILLSLOPE AREA WITH TILLAGE-INDUCED SOIL REDISTRIBUTION AND EROSION PROCESSES

C FONTANA <sup>1</sup>, C BENI <sup>2</sup>, B PENNELLI <sup>1</sup>, S SOCCIARELLI <sup>1</sup>, U NERI <sup>1</sup>

<sup>1</sup> CREA-Council for Agricultural Research and Economics, Research Centre for Agriculture and Environment (CREA-AA), ROME, ITALY

<sup>2</sup> CREA-Council for Agricultural Research and Economics, Research Centre for Engineering and Agro-Food Processing (CREA-IT), ROME, ITALY

Carbon storage in soil exceeds two/three fold the amount of C hold by plants and atmosphere. Recently, the effect of soil erosion on the carbon pool is increasingly drawing more attention. It is known in fact that SOC improves chemical, physical, and biological properties of soils, improving soil stability and structure while reducing erosion risk. Several studies have examined the relationship between soil redistribution processes (due to tillage) and SOC, to evaluate soil loss rates through the artificial radioisotope Cesium-137. As such isotope is non-exchangeable, bounds to topsoil colloids and decreases exponentially with depth, it has been used as a tracer in agricultural soils, thus establishing a significant relation between Cs-137 and SOC. In this work, the link between Cs-137, the redistribution process (soil erosion, deposition, movement and storage) and the loss of SOC was studied at CREA-IT on a hillslope area of arable land with elevated erosion risk. An adjacent area with limited erosion and sedimentation processes was chosen as background for Cs-137 fallout and decay. In January 2020, soil samples were taken at six sampling points for three depths (0-10; 10-20; 20-30) on a transect, and one sediment sample at valley bottom, to examine the link between the redistribution of soil particles and SOC at point level and slope. In the CREA-AA Laboratories, the nineteen soil samples were analyzed by gamma ray spectrometric for the concentration of Cs-137 and K-40 (GeHP - Ortec detector, efficiency 30%, Intercomparison INMRI-ENEA). Bulk density, moisture, porosity, grain size, and organic carbon were determined as well. The outcomes of this study address a significant, statistical relationship between Cs-137 and SOC that moves with the same paths and physical mechanisms sharing common dynamics, confirming the results of previous studies that used the technique of Cs-137 radioisotope as a tracer for predicting and mapping the spatial distribution of SOC in cultivated areas.

### EVALUATION OF REPEATABILITY, REPRODUCIBILITY AND RECOVERY AS ANALYTICAL CHARACTERIZATION OF THE MICRORESPTM SYSTEM, A RAPID METHOD TO ASSESS SOIL MICROBIAL RESPIRATION

M A GARCÍA-GONZÁLEZ, M S GARZÓN-MOLINA, G ARTEAGA-CLEMENTE, M GONZÁLEZ-GONZÁLEZ

Instituto Canario de Investigaciones Agrarias - Unidad de Laboratorios, San Cristóbal de La Laguna, SPAIN

Scientific evidence indicates that more than 60% of European soils are unhealthy, and this is worsening due to the unsustainable use of natural resources, particularly the degradation and pollution of soils. As part of the European Union soil strategy, the European Commission has proposed in 2023 a new Directive on Soil Monitoring and Resilience. The proposed law, which is critical for ensuring a high level of environmental and health protection through soil monitoring, establishes that biodiversity loss should be determined by measuring soil basal respiration. The reference methodology proposed is the measurement of the CO<sub>2</sub> evolution produced by soil microbiota using a respirometer. To keep monitoring costs reasonable, it is desirable to develop alternative methods for this measurement, as not all analysis laboratories have the necessary equipment. However, it is crucial to ensure that any alternative methodology provides accurate and precise results.

The objective of this study was to describe the analytical characteristics of the MicroResp™ test system, developed by Campbell et al. in 2003, which measures CO<sub>2</sub> production during short-term incubation from a whole soil microbial community, in microtitre plates. The evaluation of the accuracy of intra-day and inter-day results was determined by analyzing soils with six levels of CO<sub>2</sub> production, ranging from 1.5 to 135 mg C-CO<sub>2</sub>/kg dry soil/day, each level being measured for 3-4 soils for 3-4 days. The results are satisfactory at concentration levels between 8 and 20 mg C-CO<sub>2</sub>/kg dry soil/day and 60-140 mg C-CO<sub>2</sub>/kg dry soil/day, with coefficients of variation of 35 and 20%, respectively. A recovery study was also carried out, adding peat to the soil in different proportions until reaching a CO<sub>2</sub> concentration level between 25 and 80 mg C-CO<sub>2</sub>/kg dry soil/day; the recovery obtained at all concentration levels ranges from 62 to 149%. In conclusion, the results suggest that the miniaturized MicroResp™ method is a cost-effective and accessible alternative to most laboratories for measuring basal and induced soil microbial respiration reliably.

### OVERSEEDING WITH LEGUMES AND P FERTILIZATION EFFECTS ON SOIL P DYNAMICS IN NATIVE PASTURES OF URUGUAY

A. DEL PINO<sup>1</sup>, F. LEZAMA<sup>2</sup>, G. PARODI<sup>3</sup>

<sup>1</sup> UNIVERSIDAD DE LA REPÚBLICA FACULTAD DE AGRONOMÍA DPTO SUELOS Y AGUAS, MONTEVIDEO, URUGUAY

<sup>2</sup> UNIVERSIDAD DE LA REPÚBLICA FACULTAD DE AGRONOMÍA DPTO SISTEMAS AMBIENTALES, MONTEVIDEO, URUGUAY

<sup>3</sup> UNIVERSIDAD DE LA REPÚBLICA FACULTAD DE AGRONOMÍA DPTO SISTEMAS AMBIENTALES, MONTEVIDEO, URUGUAY

In Uruguay overseeding native pastures (NP) with legumes and fertilizer P application (NP+LP) is a popular management practice aimed to increase forage production and quality for grazing cattle. Soils in the northwestern (NWZ) and central-eastern (CEZ) zones of the country, where most of the land is under extensive grazing, are generally P deficient. Given the increasing prices of P fertilizers, efforts are required to improve P fertilizer recommendations. In this study the changes produced by NP+LP on soil characteristics, specially related to P dynamics were assessed. Additionally, we explored the possibility to complement the traditional recommendation system, based in available P levels, with other soil measurements. We evaluated pairs of NP/NP+LP sown with *Lotus subbiflorus* (10 sites in NWZ and 13 in CEZ,) in commercial farms that had been receiving P fertilizer for at least 5 years. The long-term effect of P addition reflected not only in available P level (Bray1) but also in the inorganic extractable P, and the organic P content of the soils. However, while in CEZ all these parameters showed significant effects of NP+LP, in the NWZ only the change in inorganic extractable P and the P content of organic matter reached significance. Soils in NWZ have finer textures and higher organic carbon (OC) contents than those in CEZ (average OC in the 0-5 cm layer was 59 and 26 mg kg<sup>-1</sup>, for NWZ and CEZ respectively) and these characteristics can be associated to a lower effect of fertilization in NWZ. Interestingly the P retention capacity, which showed rather high values in both zones (average 516 and 412 mg kg<sup>-1</sup>) was not affected by the change in soil management. Given the high P retention capacity of the soils the P fertilizer legacy is likely to be rather limited, therefore the annual fertilizer application with low to moderate P rates is probably adequate to maintain P availability for plants avoiding environmental hazards due to excessive P applications.

### USE OF BLENDED AMENDMENTS: AN INNOVATIVE APPROACH TO REDUCE SOLUBLE PHOSPHORUS IN SOILS

D. KUMARAGAMAGE, H. SOTO, E. VAN, D. GOLTZ

The University of Winnipeg, Winnipeg, CANADA

Phosphorus (P) loss from agricultural soils can contribute significantly towards P enrichment in downstream water bodies and impairing water quality. Application of soil amendments is a strategy to decrease soluble P in surface soils, but to be effective, the amendment should match the soil type. Blended soil amendments could be a better approach to reduce soluble P across soils; however, very little research has been done with blended amendments in reducing P loss. We hypothesized that the application of blended amendments would be more efficient in reducing the potential P loss from soils than single amendment applications. This research compared the effectiveness of gypsum, Epsom salt and alum applied singly or blended in different ratios in reducing potential P loss from two soils in the laboratory. Two soils (0-15 cm depth) with contrasting water-soluble P (<1.5 mg/L in low P soil, and >8 mg/L in high-P soil) were collected from the Red River Valley region in Manitoba, Canada. Ten treatments used for the incubation study were; unamended soil, gypsum or Epsom salt at 2.5 or 5 Mg/ha, alum at 2.5 Mg/ha, and four blended treatments of gypsum: alum or Epsom salt: alum of 1:1 or 2:1. Amended soils were incubated under saturated soil moisture in triplicates for 2 weeks at  $22 \pm 1$  C and analyzed for water extractable P and Mehlich 3-P concentrations. Water extractable P concentrations, which is an indicator of potential risk of P loss, was significantly reduced by all amendments compared to control. In the high P soils, the blended amendments (gypsum-alum or Epsom salt-alum at both lower and higher rate of gypsum or Epsom salt) performed better than a single amendment. Mehlich 3 -P, which is considered as plant available P, was not influenced by any of the amended treatments. Our results suggest that blended amendments can be more effective than single amendments in reducing potential P loss from high legacy P soils.

## 4. Soil health in achieving the Sustainable Development Goals 4.03 125012 - Matching food security and environmental goals: phosphorus, a key global element

### PHOSPHORUS AS A KEY FACTOR IN SOIL NUTRIENT ECOSYSTEMS – A CASE STUDY BASED ON LONG-TERM FIELD TRIAL DATA

C. BOJTOR, A. SZÉLES, T. RÁTONYI, P. FEJÉR, E. HARSÁNYI, J. NAGY, Á. ILLÉS

Institute of Land Use, Engineering and Precision Farming Technology, University of Debrecen, Debrecen, HUNGARY

The importance of nutrient balance in agriculture lies in promoting optimal plant growth and productivity, and it also contributes to soil fertility, sustainability, and environmental issues. Of the essential nutrients, phosphorus is a key component of the nutrient cycle. As the dynamics of phosphorus in soils involve many complex physiological processes, maintaining a balanced phosphorus cycle is crucial for sustainable agriculture.

A complex macronutrient-based fertilisation experiment taking place at the Látókép Crop Production Experimental Site of the University of Debrecen can provide valuable information about nutrient cycling in plant – soil interactions. The field experiment was established in 1983 and it has been constantly active for over 40 years, providing the reliable basis to examine and analyse the interaction of soil nutrients. The experiment includes unfertilised control plots (T0) with five treatments with increasing phosphorus levels (T1: 23 kg\*ha<sup>-1</sup> P<sub>2</sub>O<sub>5</sub>; T2: 46 kg\*ha<sup>-1</sup> P<sub>2</sub>O<sub>5</sub>; T3: 69 kg\*ha<sup>-1</sup> P<sub>2</sub>O<sub>5</sub>; T4: 92 kg\*ha<sup>-1</sup> P<sub>2</sub>O<sub>5</sub>; T5: 115 kg\*ha<sup>-1</sup> P<sub>2</sub>O<sub>5</sub>;) . The complex mineral profile of the upper soil layer was analysed in accredited laboratory, making it possible to evaluate the interactions between essential nutrients.

The findings obtained from the analysis demonstrated that increasing phosphorus fertilisation resulted in increased availability in the soil (T0: 56,39 mg\*kg<sup>-1</sup> P<sub>2</sub>O<sub>5</sub>; T5: 184,38 mg\*kg<sup>-1</sup> P<sub>2</sub>O<sub>5</sub>); which confirms the accumulation of phosphorus in the soil layer important for the plants. In contrast, the increasing phosphorus accumulation had adverse effects on the accumulation processes of the essential micronutrients. The zinc and the copper concentrations decreased significantly due to the increased phosphorus concentration (Zn: T0: 2,14 mg\*kg<sup>-1</sup>; T5: 0,51 mg\*kg<sup>-1</sup>; Cu: T0: 3,43 mg\*kg<sup>-1</sup>; T5: 1,98 mg\*kg<sup>-1</sup>).

Based on the obtained results concerning the interaction among essential nutrients, managing phosphorus inputs and promoting efficient fertiliser use are essential for maintaining a healthy phosphorus cycle in agricultural systems and achieving high grain yields and quality.

### MODELLING LONG-TERM IMPACT OF NOVEL BIOBASED FERTILIZERS ON SOIL ORGANIC MATTER STORAGE FROM LABORATORY SHORT-TERM C MINERALIZATION

E. RONCHIN, T. SINICCO, C. MONDINI

CREA Research Centre for Viticulture and Enology, Gorizia, ITALY

The growing emphasis on circular food economies and sustainable agriculture is driving the recycling of exogenous organic matter (EOM) through the production of biobased fertilizers (BBF). While this provides an opportunity to reduce reliance on mineral and synthetic fertilizers, uncertainty exists regarding the long-term impact of BBF application on soil organic matter dynamics.

This study aims to model the impact of novel BBF - such as microbial biomass, insect biomass, insect frass, biochar, and derived blends, produced in the framework of Horizon 2020 project RUSTICA - on long term soil C storage.

For this purpose, we used a modified version of the RothC model encompassing additional EOM pools. We calibrated EOM pools parameters, specifically pool size and decay rates, through inverse modelling of EOM C mineralization rates from amended soil. We performed one-month laboratory incubation experiments of soil amended with BBF and derived blends under controlled aerobic conditions (40% of water holding capacity and 20°C). Maximum likelihood estimates for EOM pools size and decay rates were inferred by a Bayesian inversion with Differential Adaptive Metropolis (DREAM) algorithm of EOM C mineralization rate. The modified RothC model with parameterized EOM pools was then used to predict the long-term effects (100 years) of BBF and derived blends on soil C stocks.

Results indicate the remarkable stability of biochar, supporting its efficacy in promoting soil C sequestration, even when blended with other BBF. Conversely, insect biomass, even in small amounts in the blend (16.7%), enhanced CO<sub>2</sub> flux, leading to lower EOM C retention. This emphasizes the need for careful consideration when incorporating specific BBF into soil management practices.

In conclusion, our study provides insights into the complex dynamics of EOM pools decomposition of novel BBF, offering a comprehensive understanding of both short-term impacts and long-term implications. These findings contribute useful information to advise sustainable soil management practices aimed to recover and enhance soil organic matter storage.

### RESPONSE OF ORGANIC MATTER POOLS IN PADDY SOILS TO DIGESTATE APPLICATION, CHANGES IN FLOODING LEVEL AND INCREASED TEMPERATURES

B. GIANNETTA <sup>1</sup>, R. BOL <sup>2,3</sup>, B. WU <sup>2</sup>, N. SIEBERS <sup>2</sup>, J.C. CACEREZ <sup>2</sup>, C. ZACCONE <sup>4</sup>

<sup>4</sup> University of Verona, Department of Biotechnology, Verona, ITALY

Changing climatic conditions represent a threat to the agricultural sustainability of paddy soils, not only because rice (*Oryza sativa*) is the main irrigated crop worldwide, but also because they represent the largest anthropogenic wetlands. Their multiple key wetland ecosystem functions also include carbon (C) sequestration. The application of anaerobic digestate represents a great potential to increase soil C sequestration. However, there is still a lack of knowledge on the fate of applied digestate and its incorporation into SOM under increasing temperatures, and about SOM stabilization processes promoted by iron (Fe) (hydr)oxides. Our research aims at gaining a deeper insight into these processes. Specific objectives are: a) to investigate the effects of increased temperature (~2°C) and reduced water levels on the amount and quality of SOM pools; b) to determine how digestate application affects SOC stability and distribution into SOM fractions; c) to assess if changes in wetting and drying cycles dictated by climate changes may alter Fe mineral dissolution and linked implications on colloidal stability and isotopic composition. The experimental design consists of 3 factors - amendment application (unamended control and digestate), climate manipulation (ambient temperature, and warming) and water management (normal supply and reduced by 30%). To capture SOM protection mechanisms, soil samples were fractionated by size following aggregate dispersion, thus resulting in a particulate organic matter (POM) and a mineral-associated organic matter (MAOM) fraction.

Preliminary results revealed that MAOM fraction was significantly affected by the flooding level and digestate application, but flooding level and warming did not significantly affect C content in the POM fraction. Our investigations of the Fe water-dispersible colloids and isotopic compositions will help to elucidate the differential mechanisms involved in paddy soil Fe cycling under variable land management and increasing temperatures.

This research has also the potential to generate the policy-relevant soil management recommendations required to underpin international programs needed to address global-change challenges and recycle organic wastes while preserving SOC.

### Body

Earthworm and *Sphingobacterium* sp. are both characterized by their strong decomposition ability of organic compound and broad distribution in soil. Little is known about their interaction on soil organic matter decomposition and whether *Sphingobacterium* sp. could assist earthworms with carbon and nitrogen cycles. Earthworms and *Sphingobacterium* sp. were inoculated in clean and contaminated soils under laboratory condition for 20 days. We investigated their single or combined effects on C and N forms and C and N related enzyme activities, evaluating their interaction on soil C and N cycles. *E. fetida* and *A. gracilis* inoculation alone increased dissolved organic carbon (DOC) contents significantly by 75.8% and 53.6% comparing with no earthworm control in clean soil; while they increased alkali-hydrolyzable nitrogen (AN) contents significantly by 32.9% and 20.9% as well, respectively. Inoculation of *Sphingobacterium* sp. alone promoted microbial biomass carbon reaching  $1685 \pm 292$  mg·kg<sup>-1</sup> in clean soil tripled of control. Moreover, the combination of earthworms and *Sphingobacterium* sp. increased DOC contents by 212% and 134%, and AN contents by 31.3% and 25.4% in treatments of *E. fetida*+*Sphingobacterium* sp. and *A. gracilis*+*Sphingobacterium* sp. in clean soil, respectively. In these two soils, most of enzyme activities were inhibited in treatments with earthworm alone and earthworm+*Sphingobacterium* sp.. However, N related enzyme activities were increased in treatments with *E. fetida* in clean soil and treatments with *A. gracilis* in contaminated soil (N-acetyl-D-glucosaminidase activities), protease activities in treatments with *Sphingobacterium* sp. and treatments with *A. gracilis* in contaminated soil (protease activities). Our results concluded that earthworm inoculation alone significantly promoted mineralization of carbon and nitrogen in clean soil rather than contaminated soil; *Sphingobacterium* sp. was able to assist earthworms with improving carbon and nitrogen mineralization in clean soil. In contaminated soil, earthworm alone and earthworm combined with *Sphingobacterium* sp. both facilitated carbon storage. These findings provided insights into the combined effects of earthworms and microbes on C and N cycling during soil remediation.

**Keywords:** Earthworm, *Sphingobacterium* sp., metal contaminated soil, C and N forms, Enzyme activities

## 4. Soil health in achieving the Sustainable Development Goals 4.04 131145 - Dynamics and functions of soil organic matter under new and traditional amendments

### BEHAVIORAL CHARACTERISTICS OF BIOCHAR IN FACILITY SOIL AND ITS INFLUENCING MECHANISM

Y. CHEN, W. HAN, Y. YI

No.120 Dongling Road, Shenhe District, Shenyang, CHINA

The excessive application of chemical fertilizer in facility cultivation generally leads to continuous cropping obstacles such as secondary salinization and nutrient imbalance, and increases the negative impact on the environment. Biochar can not only directly provide crop nutrients, but also improve soil physical and chemical properties, which has great potential in replacing chemical fertilizers. However, the effect of biochar aging on its function in the facility soil environment is not clear. Therefore, through a field experiment, this study discussed the effects of different amounts of biochar (B1: 22.5 t/ha-1, B2: 67.5 t/ha-1) and organic fertilizer (m: 90.0 t/ha-1) under different amounts of chemical fertilizer (F1: 30% fertilizer reduction, F2: 15% fertilizer reduction, F3: actual production fertilization) on the structure and fertility of the facility soil. The results showed that the humification degree of biochar decreased gradually after application, and microorganisms colonized in the pores of biochar, which promoted microbial activity and then decomposed soil organic matter and plant residues. After the application of biochar and organic fertilizer, the yield of tomato increased by 4.93-62.14% and 28.62-31.46%, respectively, and the incidence of umbilical rot decreased by 0.71-68.14% and 12.08-60.25%. Both biochar and organic fertilizer treatment increased water content, total porosity, macroporosity, NO<sub>3</sub><sup>-</sup>-N, NH<sub>4</sub><sup>+</sup>-N, DOC/DON and CEC of 0-20cm facility soil. Among them, the treatment of high amount of biochar (B2) and organic fertilizer increased the contents of NO<sub>3</sub><sup>-</sup>-N, NH<sub>4</sub><sup>+</sup>-N, DOC and DON in the 20-60 cm facility soil, which caused harm to the environment. Therefore, the combination of 30% reduction fertilizer and low amount of biochar (B1) is one of the environmentally friendly agricultural strategies to improve the physical and chemical properties of soil, reduce tomato umbilical deterioration and increase tomato yield.

### CITRUS SEWAGE SLUDGE AS NITROGEN SOURCE: EFFECT ON SOIL FERTILITY AND WHEAT PERFORMANCE

C. LUCIA<sup>1</sup>, V.A. LAUDICINA<sup>1</sup>, L. BADALUCCO<sup>1</sup>, A. DELGADO<sup>2</sup>

<sup>1</sup> University of Palermo - Department of Agricultural, Food and Forestry Sciences, Palermo, ITALY

<sup>2</sup> University of Seville - Department of Agronomy, ETSIA, Seville, SPAIN

Sludge is a byproduct generated through the physicochemical and biological processes applied in wastewater treatment facilities. It possesses the potential to serve as a sustainable source of energy and/or resources. The utilization of sludge as a raw material in various industries emerges as a promising way for waste management within the framework of the circular economy. The citrus industry is estimated to yield a sludge production ranging from 0.10 to 0.30 kg of sludge per kg of chemical oxygen demand (COD). Considering that the average COD content in wastewater is between 5 and 27 kg COD m<sup>-3</sup>, the specific productivity of sludge may range between 0.5 and 9.0 kg sewage sludge m<sup>-3</sup> of treated wastewater. The citrus sewage sludge (CSS) had a subalkaline pH and high electrical conductivity, although it is lower than 4 dS m<sup>-1</sup>. CSS has usually a high content of total N, so the C/N ratio is about 6. Among macronutrient cations, Ca is the most abundant, followed in order by Mg, P, K, and Na. Based on the above considerations, a pot experiment was conducted to explore the ability of CSS to act as a nitrogen fertilizer for wheat growth. The experiment was carried out in a growth chamber using pots with a capacity of 1 L and filled with 950 g of soil previously sieved to 4 mm and homogenised. Two distinct soil types, one with a reduced carbonate content and the other one rich in carbonates, were employed. Soils were mixed with 25% of perlite, in volume, and amended with CSS or fertilised with ammonium nitrate to supply 30 mg of N per plant. Four wheat seeds were transplanted into each pot.

The plants were irrigated daily with a nutrient solution having the following composition: K<sub>2</sub>SO<sub>4</sub>, KCl, KH<sub>2</sub>PO<sub>4</sub> and micronutrients. At the end of the experiment, lasted 80 days, soil and plants were analysed. In the poster, results will be described and discussed.

### CHANGES IN CO<sub>2</sub> EMISSIONS DUE TO INCORPORATION OF FERMENTED AND COMPOSTED RESIDUES IN UNSTABLE SOIL

L.N. CERÓN DE JESÚS, G.S. BENEDICTO VALDÉS, P. SÁNCHEZ GUZMÁN, J. SÁNCHEZ ESCUDERO, V.M. JASSO MONTOYA

Colegio de postgraduados, departamento de edafología, estado de México, México., México, MÉXICO

Soils with unstable structure present losses due to wind erosion and nutrient deficiencies. Amending soils with organic residues has already been applied for long time in agricultural systems. Composting such organic residues by aerating and regularly turning promotes microbial activity. The microorganisms use this organic content as their energy source, emitting CO<sub>2</sub> into the environment. Studies on mineralization of organic residues do not consider the effect of unstable aggregates on CO<sub>2</sub> emissions and may contribute to estimate CO<sub>2</sub> release from amended soils. The objective of this work was to quantify CO<sub>2</sub> emissions in response to the incorporation of organic fertilizers in unstable soil under olive production. Soils classified as cambisols, from Chimalhuacán, State of Mexico were used. Soil sample was sieved to a diameter of 250 µm and 200g was added in 0.5 L plastic container.

Five treatments were evaluated: 1) control treatment (TO), 2) bokashi at 2.5% (Bo1), 3) bokashi at 5.0% (Bo2), 4) compost at 2.5% (Co1) and 5) compost at 5.0% (Co2). Soil moisture was maintained at 30% and CO<sub>2</sub> flux was quantified every 48 h for 45 days, with a static chamber IRGA Ppsystem.

Soil pH and EC were determined, in a 2:1 ratio (water:soil) and the active carbon (POxC) was measured. The pH of the soils ranged from 7.7 to 8.2, being classified as slightly alkaline. The EC showed values between 0.2 and 1.3 dSm<sup>-1</sup>, however do not represent a limiting factor for the growth and development of olive crop. The cumulative CO<sub>2</sub> fluxes were 11 486, 11 494, 15 221 mg kg<sup>-1</sup> (TO, Bo1 and Bo2), 14 582 and 16 288 mg kg<sup>-1</sup> (Co1 and Co2). The highest contents of (POxC) were under treatment (Bo1) 368.57 mg kg<sup>-1</sup>.

The results of this study show (i) fermented and compost residues promotes the emission of CO<sub>2</sub> to the environment and, (ii) organic amendments improves physical and chemical condition allowing improvement unstability of soils.

### FOSTERING SOIL ORGANIC MATTER DYNAMICS AND PLANT GROWTH: A COMPREHENSIVE STUDY ON THE SOIL ORGANIC AMENDMENT POTENTIAL OF PÁLINKA SPENT WASH THROUGH COMPOSTING

L.R. BORGES SILVA, L. KARDOS, E. SIPOS

Hungarian University of Agriculture and Life Sciences, Department of Agro-environmental Studies, BUDAPEST, HUNGARY

The Pálinka distillery industry in Hungary generates significant organic waste, particularly 'spent wash' also called 'mash'. This post-distillation residue poses environmental challenges due to its high organic load, low pH, and recalcitrant compounds. This research addresses the need for a sustainable solution by focusing on composting to transform Pálinka spent wash into stable organic matter and neutralize phytotoxic substances. The study targets initial challenges—acidic pH, high moisture content, and elevated copper levels—through aerobic composting. In a lab-scale experiment, the spent wash was composted with wood chips and additives like diatomaceous earth, wood ash, vinasse, coconut fiber, andesite, calcium sulfate, ready-manure compost, and carbon. Two breathable drum composters were used, one with mash mixed solely with wood chips and the other combining wood chips with finished cow manure compost as an inoculum. Comprehensive analyses, including germination and enzyme activity tests, confirmed the unsuitability of the Pálinka mash for plant growth without being composted. Evaluating the ready-mash compost using various plants demonstrated its potential to enhance soil organic matter (SOM) levels, promote nutrient cycling, and improve soil structure. The study also addressed environmental risk factors, emphasizing composting's role in food safety. High copper levels in Pálinka spent wash were effectively reduced through composting, especially with ready-manure compost and diatomaceous earth. Wood ash, diatomaceous earth, and ready-manure compost emerged as effective treatments, showcasing nutrient supply and water retention. Stable organic matter formation, crucial for soil fertility, increased significantly, especially with ready-manure compost. Pálinka spent wash compost plays a pivotal role in nutrient cycling, converting organic nutrients into plant-available forms. Enhanced SOM positively impacts soil health, promoting efficient nutrient uptake and sustainable soil management. This research underscores the urgent need to address environmental and health risks associated with Pálinka spent wash, highlighting its untapped potential as a soil amendment for sustainable agriculture. Composting offers an innovative waste management approach for traditional industries, contributing to environmental protection and supporting sustainable agricultural practices.

**ADDITION OF FERMENTED AND COMPOSTED TOMATO (*SOLANUM LYCOPERSICUM L.*) RESIDUES AND CHANGES IN CO<sub>2</sub> EMISSIONS IN SOIL UNDER CONTROLLED INCUBATION.**

J. DIRCIO SALGADO, G.S. BENEDICTO VALDÉS, V.M. ORDAZ CHAPARRO, J. SÁNCHEZ ESCUDERO, V.M. MONTOYA JASSO

COLEGIO DE POSTGRADUADOS-POSTGRADO EN EDAFOLOGÍA, MONTECILLO, ESTADO DE MÉXICO, MEXICO

Tomato (*Solanum lycopersicum L.*) is one of the most consumed vegetables. This crop generates on average 3,070 t ha<sup>-1</sup> of residual dry matter per cycle. Such residues generally are accumulated or incinerated, causing negative environmental effects. The treatment and recycling of organic waste can be efficient through biological processes such as aerobic composting and anaerobic fermentation (Bokashi) where microbial activity is developed. Few studies evaluate the effect of amendment process on soil properties. The objective of this study was to evaluate the effects of aerobic compost and anaerobic fermentation (bokashi) of tomato residues on dynamics of a conventionally managed loam soil. Treatments evaluated were compost and bokashi at 2.5, 5% and a control treatment. The experimental unit consisted of 200g of soil sieved at 2mm in 0.5 L plastic containers, with four replicates per treatment; moisture was kept constant at 25% w/w. Treatment assignment was performed by randomization. Dissolved organic and inorganic carbon (DOC), CO<sub>2</sub> emission, labile soil carbon fraction (CO<sub>x</sub>P), organic matter (OM), total nitrogen, pH and electrical conductivity were determined. The results showed under 5% aerobic compost had highest CO<sub>2</sub> emissions with daily average of 1120.87 mg kg<sup>-1</sup>, followed by 5% fermented bokashi with 1026.84 mg kg<sup>-1</sup>. With 2.5% dose had 917.13 and 844.83 mg kg<sup>-1</sup> for compost and bokashi, respectively. Bokashi increased dissolved organic carbon by 14.61 mg kg<sup>-1</sup>, followed by compost with 12.21 mg kg<sup>-1</sup>, while in untreated soils, a decrease of -7.98 mg kg<sup>-1</sup> was obtained. For N, there was an increase of 0.44 and 0.040% for compost and bokashi, respectively. It is concluded that (i) the use of organic amendments enhances the chemical properties of agricultural soils, (ii) the addition of compost increases CO<sub>2</sub> emissions to a greater extent compared to fermented bokashi and (iii) fermented bokashi represents a fast and efficient alternative in treatment of tomato residues.

<sup>2</sup> CREA-Research Centre for Vegetable and Ornamental Crops, Pontecagnano Faiano, ITALY

Intensive farming systems, characterized by the absence of rotations, the preference of milling to plowing, mineral fertilization and the removal of crop residues, lead to negative consequences on soil quality. The loss of organic matter is one of the negative effects of intensive farming that could be counteracted by organic amendments by using different agricultural wastes to obtain positive impacts on physical, chemical, and biological fertility of soils. Soil organic matter (SOM) is a fundamental source of macro- and micronutrients for crops but also for soil microorganisms as SOM represents a substrate stimulating microbial biomass and consequently microbial activity and functionality in terms of enzymatic activities.

The aim of this research was to assess the effect of vermicompost (VC) as organic soil conditioner under greenhouse in a conventional farm and an organic farm in the Plain of Sele river in southern Italy. VC is the final product of a vermicomposting process involving synergistic action of earthworms and microbes in the bioconversion of organic matter into humus-like substances. VC derived from solid digestate from anaerobic digestion plant using livestock sewage and whey from dairy industry.

Three doses of VC corresponding to 37.5, 75 and 150 kg N ha<sup>-1</sup> year<sup>-1</sup> (VC1, VC2, VC3) were applied to solarized soil. Soil solarization was carried out during the summer time to control weeds, nematodes and soil-borne pathogens. Chemical and biochemical properties of soils sampled after 7 and 150 days from organic amendments were investigated to understand the correlation between the use of organic soil conditioners and organic C stock, nutrient availability, microbial biomass, enzymatic activity, and crop yields and quality.

VC provided more stable organic matter in soil with long term positive effects on soil quality. In addition, a greater available phosphorus was detected in the vermicompost amended soil. A significant enhancement of all biochemical properties of soil amended soils occurred in accordance with the VC dose spread in soil.

Invasive plant species pose a threat to biodiversity and can lead to ecosystem degradation, impacting soil invertebrate communities to varying extents. Despite this, there is limited understanding of how the organic matter of plant invaders influences soil properties and nematode communities. In this study, we conducted a pot experiment using non-invaded grassland soil and organic matter from two invasive plants, *Fallopia japonica* and *Solidago gigantea*, to assess and compare nematode community composition and soil properties. The treatments with organic matter from invasive plants showed a decrease in soil pH and moisture content, and an increase in organic carbon and total nitrogen. A decrease in productivity and a slowdown in nutrient cycling, as indicated by the decrease in the abundance of bacterivores and fungivorous nematodes, may be common when adding organic matter from invasive plants to the soil. Interestingly, adding organic matter from *F. japonica* decreased herbivores' nematode abundance, suggesting a potential ecologically friendly strategy against plant parasitic nematodes. The study highlights the effects of invasive plant organic matter on soil communities, emphasizing the importance of understanding these interactions for effective ecosystem management. These findings contribute valuable insights into potential strategies for mitigating the impact of invasive plants on soil biodiversity and functioning.

### EFFECT OF LONG-TERM SET-ASIDE MANAGEMENT SYSTEM ON SOIL HEALTH BY BIODIVERSITY INDICATORS

S. LANDI<sup>1</sup>, F. BINAZZI<sup>1,2</sup>, R. PAPINI<sup>3</sup>, S. DEL DUCA<sup>3</sup>, A. FABIANI<sup>3</sup>, S. MOCALI<sup>3</sup>

<sup>3</sup> Research Centre for Agriculture and Environment, CREA, Florence, ITALY

Organic matter depletion and biodiversity decline are among the major threats to soil health and agriculture sustainability. Managing set-aside land by mowing still represents an easy way to prevent land abandonment and to preserve soil biodiversity and functions, which are essential for soil fertility. Most of the studies focused on the impact of set-aside on soil biodiversity and organic C in the short-medium period, but information on the long-term effects of such practices is lacking. The present study aims to assess the potential effectiveness of set-aside for a long-time (14 years) to prevent soil health degradation.

The experimental field used in this study was in Vicarello (Pisa, Italy), where set-aside (SA) management was compared to abandoned land (AB) and conventional crops rotation (CR), and soil samples were collected in spring (before mowing) and autumn (after mowing) for two years. Different indicators were used to evaluate the soil fertility conservation and the changes in biodiversity at different scales. Soil biodiversity was assessed on microbial, nematode, and microarthropod indicators. Soil chemical analysis was also performed. TOC was consistently higher in AB fields and, to a lesser extent, in SA than in CR. In accordance with the TOC values, AB and SA showed higher microbial biomass values than CR. The lowest soil basal respiration values found in AB indicated a reduced mineralization rate of soil organic matter, confirming how natural soils are more stable but less productive and biologically active than soils agronomically managed. MDS analysis on nematode and microarthropod taxa abundance showed that SA and AB were partially separated by CR due to the increase in bacterial and fungal feeder nematodes involved in organic carbon mineralization and the enhancement of microarthropod abundance and taxa richness.

These results evidenced that SA is an intermediate step of a transition from conventional agricultural to naturalized grassland and confirmed the potential benefits on soil biological diversity and functions.

The teaching of soil sciences fails to achieve its learning objectives due, among other things, to the difficulty of accessing the information generated without images, uncompleted data, very specialized taxonomic language, nonapplications of use, and ancient and inadequate forms of teaching. In recent years, many soil information technologies have been generated. However, all this information from new technologies has yet to be put at the service of soil science teaching.

The objective was to generate a virtual museum of soil geography in Mexico as a technological tool that is very useful in teaching soils and for the general population's self-learning.

The strategy consisted of developing a website called Virtual Museum of Soil Geography of Mexico, in which a menu has been placed with options to access two video channels and two blogs. Apps have been generated with maps and soil information from Tabasco, Yucatán, Campeche y Michoacán states. The museum has five types of software to analyze data on soil, climate, agricultural water quality, and heavy metals. We have generated geopedological maps of the states of Tabasco, Campeche, Michoacán, and Yucatán, as well as digital maps of heavy metals in 14 Mexican cities.

The website of the Virtual Museum of Soil Geography of Mexico is <https://museosuelos.ciga.unam.mx/>. The following sections are in operation: The Museum, Work team, Maps, Databases, Videos, Blogs, To Read, Links of Interest, Image of the Month, and Technology.

The videos section has 250 links to YouTube; the notes section has 150 links to blogs. The virtual soil Museum is used in various university soil science courses. The web page is then a clear example of the socialization of science. The Virtual Museum of Soil Geography of Mexico is a world reference in disseminating soil sciences, with more than 37,000 visits worldwide in its first year of operation.

### SOIL QUALITY ASSESSMENT OF CULTIVATING FLOODED RICE ON HISTOSOL UNDER VARYING FLOOD DEPTHS

Y. FAN<sup>1</sup>, X. ZHANG<sup>1</sup>, A. RABBANY<sup>2</sup>, M. VANWEELDEN<sup>2</sup>, M. TROTTA<sup>2</sup>, J. BHADHA<sup>2</sup>

<sup>1</sup> Louisiana State University, Bossier, USA

<sup>2</sup> University of Florida, Gainesville, USA

Rice (*Oryza sativa* L.) is a widely grown crop globally, with continuous flooding irrigation (CFI) being a common practice. However, the optimal flood depth for soil quality is poorly understood. To evaluate soil quality across flooded rice fields on Histosols using CFI, a two-year field experiment was conducted with four different flood depths - 5 cm, 10 cm, 15 cm, and 20 cm. Nine soil quality indicators (SQIs) were used to evaluate soil quality, including bulk density (BD), water holding capacity (WHC), pH, cation exchange capacity (CEC), total phosphorus (TP), total Kjeldahl nitrogen (TKN), organic matter (OM), active carbon (AC), and soil protein (SP). Various scoring methods were used to calculate each of the SQIs, including total data set (TDS), minimum data set (MDS), linear (SQIL), nonlinear (SQINL), weighted (SQIW), and unweighted (SQIUW) scoring methods. A range of soil quality indices (SQI) was applied, including Cornell Comprehensive Assessment of Soil Health (CASH), Florida Soil Health Assessment (FSHA), SQITDS-L-W, SQITDS-L-UW, SQITDS-NL-W, SQITDS-NL-UW, SQIMDS-L-W, SQIMDS-L-UW, SQIMDS-UL-W, and SQIMDS-UL-UW. The results of the study showed that flood depth primarily affected BD ( $p < 0.001$ ), MWHC ( $p < 0.05$ ), and SP ( $p < 0.001$ ), but were not related to soil quality. Also, the principal component analysis indicated that SP, AC, and TKN were the critical soil quality indicators for evaluating soil quality on Histosol soil. Additionally, the importance of selecting soil score functions from high to low is: SQITDS/SQIMDS, SQIL/SQINL, and SQIW/SQIUW. Overall, this study provides important insights into water management in rice cultivation.

### SOIL HEALTH AS INFLUENCED BY AGRICULTURAL LAND USE CHANGES IN A HUMID SUBTROPICAL CLIMATIC REGION OF THE UNITED STATES

T. CHANG<sup>1</sup>, G. GARY<sup>2</sup>, Y.J. ZHANG<sup>1</sup>, D. REGINELLI<sup>3</sup>, J. JENKINS<sup>2</sup>

<sup>1</sup> Mississippi State University, Starkville, USA

<sup>2</sup> USDA-ARS, Genetics and Sustainable Agricultural Research Unit, Starkville, USA

<sup>3</sup> Mississippi Soybean Promotion Board, Starkville, USA

Land application of poultry litter is a common practice that is used as organic fertilizer to provide nutrients. It is considered to turn agricultural soils into a carbon sink, thus protecting against climate change. However, further research is needed on the impact of land use change from native vegetation land to agricultural lands with poultry litter application on soil health indicators. Soil samples were collected at depth of 0-15cm from a farmland with three different crop types (corn, cotton, soybean) under long-term poultry litter application and adjacent native vegetation land in Mississippi. Land use change from vegetation land to farmland significantly decreased major soil health indicators such as soil organic carbon, total soil nitrogen, extractable phosphorus, potassium, calcium, magnesium, aggregate stability, available water content and bulk density. We also assessed the correlation among soil indicators. The soil health assessment results showed that the conversion of vegetation land to farmland could decrease soil carbon content and soil health.

### IMPACTS OF REGENERATIVE AGRICULTURE ON GRASSLAND PRODUCTION: A NEW FARMLET-SCALE EXPERIMENT AT LINCOLN UNIVERSITY, NEW ZEALAND

K. WATSON, J.L. MOIR, A.D. BLACK

Lincoln University - Faculty of Agriculture and Life Sciences, Lincoln, NEW ZEALAND

Regenerative agriculture (RA) is topical worldwide for its principles around sustainable food production. The practice has been adopted in New Zealand (NZ) without any formal assessment of its total on-farm impact. We examined the effects of RA on yield and weed invasion in grassland production and whether these effects depend on soil P.

At Lincoln University, NZ, an RA system comprising species-rich pastures and 'long grass' rotational grazing (R) was created alongside a conventional system comprising current best practices (C) in soils of low (L) and high (H) fertility (10 and 20 mg P/kg). Treatments were laid out in five 4 x 4 Latin squares of 0.1 ha plots. Plots of the same treatment were rotationally grazed by a flock of sheep at 10-14 ewes/ha.

We analysed dry matter (DM) yield and weed content for two Latin squares, from sowing (10-13/12/2021) to 30/6/2022 (establishment) and 28/6/2023 (year 1). Seed sown was R: a 12-species mix of six grasses, two herbs and four legumes and C: a monoculture of *Medicago sativa*. Fertiliser input was 4 t lime/ha, L: 4 P and 10 S kg/ha and H: 64 P and 116 S kg/ha.

At 18 months, we found no differences in yield (mean 14,290 kg DM/ha) and weeds comprised 7% of yield for L compared to 14% for H ( $p=0.022$ ). For the first 6 months, there were no yield differences (mean 4,770 kg DM/ha) and weed was 15% for L and 29% for H ( $p=0.004$ ). Over the next 12 months, yield was lower for R than C at 8,660 and 10,380 kg DM/ha ( $p=0.048$ ) and there were no differences in weed content (mean 5%).

RA did not enhance yield and weed suppression. The 1.7 t DM/ha of lost yield across fertility levels for year 1 suggests a reduced utilisation of water, nutrients and light. This initial result requires further examination across the full design and duration (6 years) of the experiment.

### SOIL HEALTH INDICATORS AND CROP PRODUCTION IN RESPONSE TO LAND USE AND MANAGEMENT CHANGE

W. DAI <sup>1,2</sup>, G. FENG <sup>1</sup>, Y. HUANG <sup>1</sup>, A. ADELI <sup>1</sup>, J.N. JENKINS <sup>1</sup>, D.B. REGINELLI <sup>3</sup>

<sup>1</sup> USDA-ARS, Genetics and Sustainable Agricultural Research Unit, Mississippi State, USA

<sup>2</sup> ORISE Postdoctoral Research Fellow, Oak Ridge, USA

<sup>3</sup> Silver Bayou Consulting, Inc., Starkville, USA

Changes in land use could have a substantial impact on soil health, as a result, could significantly affect crop yields. The objective of this study was to explore the effects of converting native vegetation lands to cultivated lands and the subsequent long-term intensive management on soil health indicators in the southeast USA. We compared soil health of land use change and investigated soil health indicators of cultivated lands as affected by different land management practices [including broiler litter (BL), BL in combination with flue gas desulfurization gypsum plus lignite (BL + FGD + Lignite)]. The soil health indicators we measured included soil bulk density, soil water-stable aggregates, pH, total nitrogen, phosphorus, potassium, soil organic carbon content and storage, as well as C/N ratio in the soils of native vegetation lands and cultivated lands. The results revealed a noteworthy increase in soil organic carbon content and storage, pH, total nitrogen, phosphorus, potassium, C/N ratio, and water-stable aggregates following the conversion of native vegetation lands to cultivated lands. Meanwhile, soil bulk density experienced a significant decrease. These findings suggest that the land-use conversion and subsequent long-term intensive management have significantly contributed to sustaining soil fertility and quality, thereby benefiting soil health. Moreover, we also observed that after native vegetation lands were converted to cultivated lands, the corn grain yield significantly increased, which may be attributed to changes in soil nutrient supply. In conclusion, our study suggests that the conversion of native vegetation lands to cultivated lands, coupled with subsequent intensive management practices, is beneficial for enhancing soil health and fostering increased corn grain yield. Therefore, for the development of sustainable cultivated lands, future management practices, such as the application of BL or BL + FGD + Lignite, which effectively increases nutrient input into soils, should be explored and implemented.

<sup>3</sup> Mississippi Soybean Promotion Board, Starkville, USA

Land use change alters soil properties and soil health and thus affects the ability of resilience to climate change. High tunnel cultivation is an economical and high-return agricultural land use management. This study investigated the effects of changes in land use on soil health indicators. Soil samples were taken from high tunnel vegetable farms, and soil from a nearby vegetation land was used as a reference. Land use change from vegetation land to high tunnel cultivation significantly increased soil organic carbon, pH, nitrogen, phosphorus, potassium, calcium, and magnesium, with varying degrees in the 0-15cm soil layer, but decreased soil field water capacity, wilting coefficient and available water content. Cluster analysis results showed that soil properties in high tunnel cultivation were quite different from that in vegetation land. The soil health assessment showed that high tunnel cultivation increased overall soil health compared to vegetation land. The study highlights that the conversion of vegetation land to high tunnel cultivation in increase of soil health. However, organically managed high tunnel soils are at risk of alkalization also at risk of alkalization.

<sup>3</sup> Institute of Natural Resources and Agrobiology, Seville, SPAIN

The Soil Biological index (QBS-ar) combines the biodiversity of soil mesofauna community with the degree of soil animals' vulnerability and provides information on the soil biological quality, which is an indicator of degradation. The QBS-ar index is a metric index applied mostly in Mediterranean environment, in different land uses and managements always proving to be an excellent tool to quickly and inexpensively determine soil health. On the last few years thanks to the internal and scientific network activities of EJPsoil projects (MINOTAUR, Energylink) the index has been also proposed as a parameter for the evaluation of soil biodiversity related to mesofauna and also used in conjunction with other biological indicators or functional indicators. Although widely used in the Mediterranean climate (especially in Italy), it is necessary to standardize its application in different climatic contexts. Within the activity of Energylink project, we collected mesofauna in three long term agroecological experiment (LTE): an Olive orchard with mixed cover from Spain, biochar and mixed cover soil from Italy and Vineyards with bare interrow space and with permanent grassland from Slovenia. Sampling was done in late autumn 2022 (November) and late spring 2023 (June), air temperatures were considered with other soil characterization parameters. To calculate the QBS-ar and other related indexes we used the toolbox proposed to standardize the procedure.

The results showed that seasonality is the key factor influencing the mesofauna-based indexes in Mediterranean environment, while in temperate climates the seasonality on results is less pronounced. Data from Spain show a significant decrease in mesofauna in late spring, likely attributed to the extremely high temperatures. However, the results from Spain exhibited a more refined discrimination of the effect of agronomic practices on soil health than those from Slovenia and Italy. This result may be useful for giving correct technical and methodological information on the application of the mesofauna-based indices in order to standardize them across different climatic contexts.

Biological invasions represent one of the most dramatic threats to biodiversity. The effects of biological invasions are more evident on the islands for their fragility and the presence of several endemisms. *Carpobrotus* spp. and *Opuntia* spp., the most widespread invasive alien plants in the Mediterranean islands, already exert ecological impacts on natural vegetation and soil physical-chemical properties, while the effect on microarthropod communities is still unknown. For this reason, in 2023 their potential impact on microarthropod communities was assessed in Giglio e and Capraia islands of the Tuscan Archipelago.

In Giglio island, 18 randomly placed 4 m<sup>2</sup> quadrat plots in the Mediterranean garigues were surveyed: six invaded by *Carpobrotus* spp. to assess its ongoing impacts, six where the species was eradicated one year before to evaluate the recovery of the community, and six naturally uninvaded by the species as control. In Capraia island, 12 (4 m<sup>2</sup> quadrat) plots, six invaded by *Opuntia stricta* and six uninvaded as control, were randomly selected. In each plot, soil samples (10 cm cube) were collected using a special corer for the mesofauna sampling. Microarthropods were extracted from the samples using modified Berlese-Tullgren funnels following a standard methodology, were observed at the stereomicroscope, and classified at level order. Moreover, several indicators were calculated to evaluate soil health.

*Carpobrotus* spp. and *Opuntia* spp. showed a different effect on microarthropod communities. In Giglio island, the presence of *Carpobrotus*, due to the relevant changes in vegetation and soil, the abundance and biodiversity of microarthropods increased as evidenced by Dominance, Simpson, Shannon-Weiner, Brillouin, Equitability, and Berger-Parker indicators. On the contrary, the invasion of *O. stricta* seems not to significantly change the microarthropod communities and only QBS-ar value resulted lower in invaded plots. Further analyses are necessary to evaluate the impact of these two invasive alien plants considering a multi-taxa approach and the complex interaction in the soil environment.

### SOIL BIOLOGICAL QUALITY INDEX BASED ON EARTHWORMS (QBS-E) IN STRIP CROPPING VERSUS PURE STANDS: PRELIMINARY RESULTS OF THE ORTOBIOSTRIP PROJECT

M. MONTICELLI, M. COLETTA, A. TORRESI, L. SALVATORI, M. MARCONI, A. LA TERZA

University of Camerino - School of Biosciences and Veterinary Medicine, Camerino, ITALY

Climate change and intensive use of fertilizers and pesticides have reduced soil biodiversity and its long-term provisioning of ecosystem services. Several EU and worldwide initiatives recognize and address these challenges by promoting sustainable agricultural practices, such as use of cover crops, minimum tillage, and crop diversification. These include strip cropping, an agroecological technique consisting in planting different crops in alternating strips in a rotational system. This increases diversification not only in time but also in space. The main aim of this study, which is part of the OrtoBioStrip (OBS) project, is to assess the soil health status in strip cropping compared to pure stands using chemical-physical parameters and the soil biological quality index based on earthworms (QBS-e) over a period of 2 years. Earthworms have long been known to be important contributors to organic matter decomposition, water drainage and food production, and are therefore commonly used as bioindicators. QBS-e is a recently developed index and our further aim is to consolidate its use as a reliable proxy of soil health. Here we present data from the first year of monitoring carried out on 2 farms in Marche region. In spring 2023 strips and pure stands were cultivated with wheat, faba bean and clover, and earthworms were extracted from 30x30x20cm soil monoliths by hand sorting. They were counted and classified into ecological categories and species using morphological keys. Overall, 117 individuals, belonging to 3 ecological categories and 6 species were identified. Preliminary data showed that compared to pure stands, strip cropping did not significantly affect earthworm communities. Earthworms seem to be rather influenced by either fertilization or soil moisture. For the next sampling season, it is planned to use allyl iso-thiocyanate to chemically expel earthworms (including anecic ones) and to increase the number of replicates to improve the sample representativeness. At the end of the project, soil quality and agronomic data will be integrated to better understand overall strip cropping performance.

**Keywords:** earthworms,QBS-e,agroecology,strip cropping,soil health

### SETTING-UP OF MEDITERRANEAN CAMBISOL MESOCOSMS FOR ASSESSING CHEMICAL AND MICROBIAL FEATURES RELATED TO MESOFAUNA COMMUNITY HEALTH

L. D'AVINO<sup>1</sup>, M.A. GAMBELLI<sup>1</sup>, C. BECAGLI<sup>1</sup>, M.T. RODINO<sup>2</sup>, M. PITTARELLO<sup>2</sup>, M.R. PANUCCIO<sup>2</sup>, A. GELSOMINO<sup>2</sup>

<sup>1</sup> Council for Agricultural Research and Economics (CREA), Research Centre for Agriculture and Environment, FLORENCE, ITALY

<sup>2</sup> Mediterranean University of Reggio Calabria, Department of Agricultural Sciences, REGGIO CALABRIA, ITALY

Mesocosms constitute simplified models of natural ecosystems and represent useful tools for developing hypotheses on the soil-plant relationship that can realistically represent certain complex interactions of natural systems and provide information that is more immediately referable to field dynamics. Moreover, in interdisciplinary research on soil systems, mesocosms help find correlations between chemical indices and ecological ones. In the present research mesocosms have been used for assessing the environmental fate of biodegradable mulch films (either commercial such as Mater-Bi© and polyethylene, or innovative prepared from biopolymers of plant and algal cell wall) as linked to the activity of prokaryotic communities and soil-dwelling fauna. The experimental set-up, located at the University of Reggio Calabria (Italy), consists of confined mesocosm-type units made up of polyethylene conic washtubs (41 cm height, 50 cm major diameter; 50 dm<sup>3</sup> inner volume), provided with an internal draining gravel-type layer and bottom openings, which were placed in the open field by burying them in appropriately dug trenches, to allow the colonization of resident soil-dwelling organisms. Before burying, each mesocosm was filled with a soil/perlite mixture (80/20, v/v) and then added with 1 kg dry matter mature compost. The soil (Calcari-Fluvic Cambisol) was taken from the Ap horizon of a sandy loam citrus grove soil evolving over Holocene fluvial deposits. Initial mesocosms soil characterization involved a number of physical (moisture), chemical (TOC, total N, pH, CE) and biochemical (R<sub>bas</sub>, MBC, MBN, qCO<sub>2</sub>, qMin) properties related to mesofaunal biological forms indices (Acari/collembola, richness, Shannon, total abundance, QBS-ar, QBS-ar\_BF). The results highlighted that in soils removed from their original environment and potentially subjected to a divergent evolution, chemical, biochemical and mesofaunal properties were evenly and equally represented in all mesocosms at the initial stage, thus confirming their high representative value as simplified ecological models to fully investigate soil health and responses to external factors.

Earthworms are a commonly used indicator for soil health, as they play a crucial role in many soil processes and constitute a major part of soil organism biomass. One of the most important drivers of earthworm biodiversity is agricultural land use, since tillage, fertilization or the use of agrochemicals are known to affect earthworm communities. However, it is rarely investigated to what extent soil properties and climatic factors interact with this influence of agricultural activities. To study this, we analyzed datasets of earthworm surveys in 35 European countries covering different land uses, soil types, and climatic regions. Investigations were performed within the project MINOTAUR of the European Joint Programme Soil. Data on earthworm abundance and biodiversity in agroecosystems was collated by extracting it from literature, as well as from open access data bases such as GBIF, Edaphobase, datadryad, and zenodo. To prevent a publication bias, historical and non-English studies were also included. In addition, long-term ecological research sites were sampled for earthworms as part of the project. The greatest challenges in the data collation process were the heterogenous character of the data concerning e.g. species nomenclature, and the sometimes lacking meta-data regarding sampling methodology, and agricultural activities, soil properties, and climate at the study sites. Thus, preliminary outcomes of our analysis are (i) the need for data harmonization in biodiversity research to increase reusability of data in the future, (ii) the inclusion of a minimal set of meta-data in order to be able to examine the drivers of earthworm communities in agricultural systems. After a tedious data harmonization process, we will analyze our data using structural equation models, to determine which factors had the biggest impacts on earthworm abundance and biodiversity. This information then allows a better understanding of earthworm communities within agroecosystems, and to promote strategies to foster soil protection and earthworm biodiversity on a European scale.

### IMPACT OF TILLAGE PRACTICES ON SOIL MESOFAUNA COMMUNITY: A COMPARATIVE STUDY IN SLOVENIA

V. NAGLIC <sup>1</sup>, N. SIBANC <sup>2</sup>, T. GREBENC <sup>2</sup>, I. BERTONCELJ <sup>1</sup>

<sup>1</sup> Agricultural Institute of Slovenia, Ljubljana, SLOVENIA

<sup>2</sup> Slovenian Forestry Institute, Ljubljana, SLOVENIA

This study presents a detailed evaluation of the impacts of various tillage practices on soil mesofauna community, within the context of Slovenian agriculture. Conducted at the Centre for Research and Trials Jablje in central Slovenia, our study compared the effects of conventional, minimum, and no-tillage practices on soil biodiversity using a modified Quality of Biological Soil (QBS) index coupled with other diversity indices. The QBS classifies soil microarthropods into EMI forms according to their level of adaptation to the soil environment.

The two most abundant groups in our samples were Acarina (mites) and Collembola (springtails), accounting for 67.23% and 29.41% of all microarthropods, respectively. These groups showed notable variation in population densities with minimum-till supporting higher abundances of Collembola compared to conventional tillage. Both minimum and no-till supported higher abundances of hemiedaphic EMI forms compared to conventional tillage. Statistical analyses revealed a significant correlation between plant-available potassium with higher abundance of microarthropods at sites with higher potassium content.

According to the traditional QBS-ar index, which does not consider abundance and is based on the number of highly edaphic EMI groups, no-tillage obtained the highest value of 105.7. Whereas minimum tillage practices exhibited the lowest QBS-ar index value of 94.7. The Shannon and Simpson diversity indices showed analogous results. Adapted QBS-a index (taking abundances into account) showed contrasting results, classifying minimum tillage soil as of highest quality, followed by no-till and lastly conventional tillage.

Minimum tillage and no-till were shown to exhibit higher diversity and abundance of soil mesofauna, likely due to reduced soil disruption providing a favorable habitat. The positive correlation of soil mesofauna abundance with potassium content suggests that potassium creates more favorable conditions for higher soil fauna abundance either directly or indirectly by improving plant health and soil structure.

This study underscores the ecological benefits of reduced tillage practices, with minimum tillage farming particularly conducive to a diverse and abundant soil biota, thus promoting soil health and sustainability.

<sup>3</sup> Department of Chemistry, Universidad Técnica Federico Santa María, VALPARAISO, CHILE

The use of mercury to extract gold has been documented for centuries and is still used by small-scale gold miners in some countries. This practice is considered the world's largest emitter of this pollutant. Primary metal production alone releases 838 tons of mercury per year to air, water and soil. Several worldwide initiatives are currently underway to eradicate the use of mercury due to the serious environmental and health impacts they cause (UN, Minamata Convention on Mercury, 2013).

However, the levels of mercury and other heavy metals in the region's abandoned tailings are a latent threat, so it was proposed to study the current situation in order to propose the best mitigation strategies for mercury and other heavy metals present in abandoned gold and silver tailings near human sites and agricultural land. In the current research, the concentrations of mercury and other elements from the field analysis carried out in 9 abandoned tailings in the Copiapó Valley are presented. For this purpose, a Handheld X-ray Fluorescence Analyzer, the S1 Titan (Bruker, USA), was used to perform trace element measurements in situ. Subsequently, samples taken at these same sites were also analyzed by ICP-MS to confirm and validate the XRF technique for its use as a rapid, non-destructive measurement of heavy metals in this type of environmental matrix.

Results show high levels of mercury (>2500 ppm) and other heavy metals such as copper (>1800 ppm), arsenic (>2800 ppm), zinc (>10000 ppm), lead (>3900 ppm) and barium (>16000 ppm), confirming the danger of these sites, which in most cases are without access restrictions and very close to human settlements. The presence of high concentration of mercury was confirmed in the field (tailings and soil), as well as the other elements analyzed, all toxic to health. The best options for mitigation, adapted to local conditions, are currently being evaluated and will be presented as alternatives to decision-makers

### AGROFORESTRY AS A SOIL RECOVERY STRATEGY IN DEGRADED NATIVE NOTHOFAGUS OBLIQUA FORESTS IN CHILE

C. CAMILA RAMOS CARRERAS<sup>1</sup>, F. DUBE<sup>2</sup>, L. PAULINO<sup>3,4</sup>, E. ZAGAL<sup>3,4</sup>

<sup>1</sup> Doctoral Program in Agricultural Sciences, Faculty of Agronomy, University of Concepción (UdeC), Chillan, CHILE

<sup>2</sup> Faculty of Forest Sciences, (UdeC), Concepción, CHILE

<sup>3</sup> Soil and Environment Laboratory, Chillán Campus, UdeC, Chillán, CHILE

<sup>4</sup> Department of Soils and Natural Resources, Faculty of Agronomy, UdeC, Chillán, CHILE

In Chile, approximately 37.8% of the national territory is affected by land degradation ranging from moderate to severe, primarily due to anthropogenic activities. About 44% of native forest in the southern part of the country has been partially replaced by livestock farming, particularly affecting the *Nothofagus* genus, with up to 70% loss of its original area. In response to this concerning degradation, agroforestry (AFS) stands out as a key climate solution, recommended by organizations such as the IPCC and FAO, for its ability to sequester organic carbon in the soil, in addition to reducing greenhouse gas emissions, conserving biodiversity, building resilience, and halting deforestation. Therefore, this study focused on determining the impact of agroforestry on a degraded native forest of *Nothofagus obliqua* in Ranchillo Alto (37°04'52' S, 71°39'14' W), Ñuble Region. The study sites were classified according to previous canopy disturbance levels (+): open (Op)+++, semi-open (SOp)++, and semi-closed (SC)+. Physical, chemical, and biological properties of the soil were determined at depths of 0-30 cm and 30-60 cm. The results indicated that the topsoil horizon of 0-30 cm showed the most significant findings in all analyzed soil properties. Physically, the soils showed little variation among canopy disturbance levels, remaining within typical ranges for andisols. Chemical properties showed that the carbon (C) and nitrogen (N) contents varied between 7.9 and 10.1 ± 0.4%, and 0.4 to 0.6 ± 0.03% for C and N, respectively. The highest concentrations were found in the Op canopy. This condition could have been influenced by historical anthropogenic practices, such as agricultural burning, leading to the generation of pyrogenic carbon. Biological analyses showed greater microbial activity in the (SC) +, influenced by leaf litter and site conditions. The accumulation of organic soil carbon showed a sustained increase from 2015 to 2023 in all canopy conditions, demonstrating the capability of AFS in the recovery of soils in degraded native forests and their role as carbon sinks.

### LAND USE CHANGE DYNAMICS IN TWO CONTRASTING MEDITERRANEAN WATERSHEDS (1977-2022) AND THEIR EFFECT ON SOC STOCKS

J.A. SILLERO MEDINA<sup>1</sup>, A. TRIANO CORNEJO<sup>2</sup>, M.E. PÉREZ GONZÁLEZ<sup>3</sup>, J.D. RUIZ SINOGA<sup>1</sup>

<sup>1</sup> Habitat, Territory and Digitalisation Institute - IHTD, University of Málaga, Málaga, ESPAÑA

<sup>3</sup> Department of Geography, University Complutense of Madrid, Madrid, ESPAÑA

Mediterranean region, according to the latest IPCC report, is particularly vulnerable to the impacts of climate change. This vulnerability is exacerbated by intense human activity and frequent changes in land use, leading to a notable increase in erosion and degradation processes. As a direct consequence, there is a decline in soil health and, within it, the capacity to retain organic carbon is reduced. In this context, this study aims to: (i) analyze changes in land use over the past decades (1977-2022); (ii) estimate which land uses have a higher soil of organic carbon (SOC) stocks through the collection and analysis of a total of 145 soil samples; (iii) assess the link between current SOC stocks and land use dynamics in recent years; (iv) evaluate the importance of climatic characteristics in SOC stock; (v) generate detailed SOC stocks mapping using Random Forest. For this purpose, two small Andalusian Mediterranean watersheds with contrasting climatic conditions have been selected: on one hand, a watershed (C1, Arroyo de la Pindolita – Valle del Río Genal) characterized by a subhumid Mediterranean climate ( $\pm 700$  mm of annual rainfall); on the other hand, a watershed (C2, Rambla del Serrón – Campo de Tabernas) with arid conditions ( $\pm 150$  mm of annual rainfall). The results show how the contrasting dynamics in land use changes and climatic conditions, especially rainfall, determine a highly differential behavior between the two watersheds. C1, mainly occupied by agricultural land and with a high dynamism in land use changes, has higher SOC stocks, a fact clearly conditioned by climatic characteristics favoring a biostasis situation. Meanwhile, C2 has seen a significant increase in built-up areas and land dedicated to irrigation crops, especially in recent years, identifying generally low SOC stocks.

### IS IT POSSIBLE TO RECARBONIZE AND RECOVER SOILS FROM CONSTRUCTION AND DEMOLITION WASTE - CDW (BOGOTÁ D.C.- COLOMBIA) USING BIOSOLIDS?

L.V. VARGAS GUERRERO, L. FIGUEROA DEL CASTILLO

Universidad El Bosque, Bogota, COLOMBIA

Nobel Prize winner, Dr. Rattan Lal, states that “Recovering degraded soils is the best way to mitigate climate change”, added to the initiatives of the RECSOIL tool, (COP 23, 2017) of the UNFCCC, whose objective is to promote sustainable soil management focused on promoting the increase of SOC, which is why it was of interest to study one of the industrial activities that generate great impact: CDW and biosolids, considered in Colombia as a problem environmental, ignoring its potential.

Initiatives that allowed the development of this research in 2023 on a soil classified as Pachic Melanudands-Andic Dystrudepts- Aeric Endoaquepts- Aquic Hapludands complex, with a sandy frank texture . The methodology used was QGIS, Vicente Conessa, environmental impacts matrix, column study to develop using PVC tubes according to a model by Soriano-Disla et al. (2010), to established 3 treatments X 3 with soil: biosolids dose ratios TO Control: 1:0, T1:1:2, T2:1:4, Pearson correlation, T Student and RStudio to comprobe the null hypothesis 'All doses of biosolids from the evaluated treatments contributed to the recarbonization and recovery of the soil at the CDW'. Experiment located in Chia - Universidad El Bosque for 4 months, with periodic controls of soil humidity, pH, CE and soil temperature.

After the time of the experimental phase, for the soil health and quality indicators, the following results stand out: an increase in SOC of 246% (T1) and 301% (T2), C.E of 226% (T1) and 291% (T2), C.I.C of 156% (T1) and 179% (T2), C/N of 101% (T1) and 102% (T2), gravimetric moisture of 228% (T1) and 379% (T2), and the soil aggregate stability transitioned from highly unstable to very stable. The best Pearson correlation coefficients were 0.95 between SOC and NT, 0.89 between SOC and C.E, and SOC with C.I.C, 0.87 SOC and gravimetric moisture, and 0.84 between SOC and aggregate stability. This research is considered as input to achieve specific goals of SDGs 12, 13 and 15.

Soil organic matter (SOM) content and composition are among the most effective soil health and fertility drivers. SOM determines the most physical and chemical soil functions, and it has an essential role in food security and climate change related challenges. However, the dynamics of SOM decomposition and stabilization ways in various environments on a country scale are not entirely understood. The present study, therefore, was devoted to identifying the role of environmental properties in SOM concentration and composition variations on a country scale in Hungary. Soil samples from the uppermost, potentially tilled horizon (2–20 cm) were fractionated to determine the sequestered organic matter directly bound to the fine mineral fraction (< 20 µm) (MAOC). Altogether, 87 soil samples were fractionated from various land uses, parent materials, soil types, and environmental conditions. Consequently, the recalcitrant organic carbon concentration in the fine fraction scattered widely (0.5–14.1%) and was independent of that of the bulk soil. Instead, it was a function of the aromaticity of the bulk SOM and slope steepness. This finding suggests potential changes in the MAOC both in terms of concentration and composition due to microbial decomposition, indicating that recalcitrance by the mineral phase does not necessarily mean absolute protection. Land use seemed to affect SOM C/N ratios probably via plant residue composition, whereas aromaticity was a function of climate and soil properties, indicating the highlighted role of microbial activity. The study was supported by the Eötvös Loránd Research Network (SA41/2021).

### EFFECTS OF LONG-TERM ENHANCED GAME POPULATION DENSITY ON SOIL PHYSICAL, CHEMICAL, AND MICROBIOLOGICAL PROPERTIES

M. GERZABEK<sup>1</sup>, H. GERZABEK<sup>1</sup>, E. INSELBACHER<sup>1</sup>, U. NOPP-MAYR<sup>2</sup>

<sup>1</sup> University of Natural Resources and Life Sciences Vienna, Department Forest and Soil Sciences, Vienna, AUSTRIA

<sup>2</sup> University of Natural Resources and Life Sciences Vienna, Department Integrative Biology and Biodiversity Research, Vienna, AUSTRIA

Information of the impact of a high game density, which leads to high nutrient and carbon inputs via excrement and, in the case of feeding, via fodder inputs, on forest soils is almost lacking. We aimed to investigate the effect of long-term enhanced game population density on soil properties. The study site is located in Lower Austria, and consists of a fenced area (enclosure) with high game population density and a directly adjacent control area, an open forest with lower game density. Both areas contain monoculture stands (*Robinia pseudoacacia* (RP), *Pinus nigra* (PN), *Quercus robur* (QR), *Pinus sylvestris* (PS)). Soils were sampled in three depths down to 50 cm in each of the stands. Soil samples were analysed for contents of total OC and N, non-purgeable organic C (NPOC), total dissolved N (TDN), and microbial biomass C and N. We found significant differences of all parameters between the enclosure and the control area. Overall, the total OC and N as well as microbial C and N was higher in the control area, likely due to a denser understory vegetation, which was almost missing in the enclosure due to browsing. NPOC and TDN contents were higher in the enclosure indicating a higher turn-over rate of plant-available nutrients attributable to the high game animal density. Further, tree species and soil depth had a strong influence on soil parameters (especially total N, NPOC, TDN, microbial N) between inside and outside the enclosure. In detail, RP exhibited the highest total N, TDN and microbial N contents reflecting its N-fixing capacity. Furthermore, the largest interaction between tree species and enclosure vs. control area was also found for RP. These results show a clear influence of game animal density in combination with tree species on important soil properties. Future studies should include a broader variety of soil physical, chemical and biological properties, as well as stand productivity thus linking game density and forest ecosystem dynamics.

The estimation of Soil-based Ecosystem Services (SEs) is crucial for land management. This work presents a quantitative approach to evaluate the water regulation SEs: two web-based dynamic tools to assess and map the soil filtering capacity to both pesticides and nitrate (the LandSupport Geospatial Decision Support system).

The pesticide fate tool simulates the transport of reactive solutes, i.e. pesticides, and maps the percentage of pollutant mass that reaches the groundwater depth within a user-defined time interval. The tool integrates the extended transfer function model (TFM-ext); inputs are the soil and the vadose zone physical and hydrological properties, the climate, the groundwater table depth, and the crop-specific management (sowing and harvesting dates, pesticides doses and time of application).

The nitrate fate tool simulates the crop growth dynamics and assesses nitrate transport through the unsaturated zone until the groundwater table depth. The output maps represent the number of years for the arrival to the groundwater of 50% of the mass of nitrate leachate from the root zone. The tool is based on the coupling of the dynamical crop-growth ARMOSA model and of the TFM-ext model and its main inputs are the type of crop and/or crop rotation and related management (tillage, irrigation, fertilization, and residues), the soil physical and hydrological properties, the climate and the groundwater table depth.

This work presents the implementations and applications of both tools in three European case studies (Campania Region-IT, Marchfeld Region-AT, Zala County-HU), with two climatic datasets (baseline, future projection with RCP 4.5 and 8.5).

Scavenging is an important ecological process that facilitates the removal of carrion from the landscape, thereby contributing to the recycling of nutrients and ultimately stabilizing food-webs). In addition, by decreasing the time that carrion persists in the field, scavengers are regarded as pest and disease regulators, leading to tangible benefits to humans. Among all scavenger species, terrestrial vertebrates are especially relevant because they can consume large amounts of carrion over short periods of time. Therefore, insights into the organization of vertebrate scavenging assemblages around carrion resources are critical to understanding their broader contribution to ecosystem processes linked to decomposition.

On the other hand, soils represent the most biologically diverse and important ecosystem on the planet. Most of the biodiversity of ecosystems is found in the soil, about one gram of soil may typically contain one billion bacterial cells, that corresponds to about ten thousand different bacterial genomes, up to one million individual fungi, about one million cells of protists, and several hundred of nematodes.

In this sense soil microbiota and its function are extremely sensible to any change on the soil. The presence of carrion on the soil and the dynamic of scavengers can significantly modify the balance of nutrients in the soil that will affect to the structure and biodiversity of soil microorganisms. This important interaction has not been researched and there is not enough information about the effects of scavengers on soil properties.

In this study it has been evaluated the consumption process of ungulate carcasses (aoudad *Ammotragus lervia*) in the Sierra Espuña Regional Park (Murcia, SE Spain), in relation to the chemical and biochemical soil properties (organic carbon, N, P and K. Microbial biomass, soil respiration and enzymatic activities

The results show that most of the soil properties studied have been improved.

Soil is essential for the environment, and also for the ecosystem's services that benefit humans. It is a finite component exposed to threats of loss which are origin or intensified by disturbances like forest fires; nevertheless, the positive or negative effects, impact differently on each type of ecosystem. The objective was asses the changes in the properties of soils of volcanic origin down sites affected by forest fires of moderate severity and high severity, to 2 days and 5 years after the disturbance. In the Tlaloc mountain, Texcoco, Mexico there are Andosols down Mix Forest. By Procedures for Soil Analysis of Van Rewdjik (2002), we realized chemical and physical determinations on soil samples affected and not affected by forest fire, which we recollected at 0-10 cm depth. The main changes occurred on the sites with high severity, where the fire reached de top trees and, the soil reached temperatures  $> 250^{\circ}\text{C}$ . Immediately after the fire forest the calcination of leaf litter, branches, and left provided Na and K to the soil, causing a percentage increased interchangeable bases; besides, the loss of organic matter caused aggregates to decrease in size and formed pseudo sands. In both severities, the changes in chemical and physical properties of soils come back to a similar condition to no affected soils after 5 years. We concluded that soils formed at volcanic ash are soils are capable of recovering, although fire severity high.

### VARIABILITY OF RUSLE FACTOR K IN GRASSLANDS FROM HIGH MOUNTAIN ENVIRONMENT (SIERRA DE LAS NIEVES, SOUTHERN SPAIN)

J. MARTINEZ-MURILLO <sup>1</sup>, M. MENJIBAR-ROMERO <sup>2</sup>

<sup>1</sup> Laboratory of Geomorphology and Soil, University of Málaga, Málaga, SPAIN

<sup>2</sup> Laboratory of Geomorphology and Soil, University of Málaga, Málaga, SPAIN

#### Body

United Nations declared the majority of world's soil resources are in only fair, poor or very poor condition from soil degradation, so soil erosion is a major threat to soil. Mainly, this is the result of accelerated soil erosion processes as consequences of deforestation, overgrazing, tillage and unsuitable agricultural practices. Impacts can be severe, not only through land degradation and fertility loss, but through a conspicuous number of off-site effects leading to desertification.

In one Mediterranean high mountain environment (Sierra de las Nieves, southern Spain), this study deals with the calculation of the RUSLE Factor K in grassland soils with different degrees of degradation due to grazing and water erosion. Also, Factor K is determined for badland materials as final stage of grassland degradation. To do this, soil surface conditions is described in three different types of grassland: non-degraded, semi-degraded, and degraded, besides in badland surface material. 10-soil samples from 0-10 cm of depth are taken in all of them to analysis in laboratory: bulk density, texture, organic matter content, permeability, and aggregate stability fraction. Finally, the Factor K is calculated based on the soil data.

The results show a declining trend and significant differences between the sampled grassland and badland material: non-degraded  $0.36 \pm 0.14$ , semi-degraded  $0.56 \pm 0.13$ , degraded  $0.68 \pm 0.12$ , and badland material  $0.74 \pm 0.05$ . These significant differences are not achieved regarding mean aggregate stability fraction: non-degraded  $28.7 \pm 10.5\%$ , semi-degraded  $35.8 \pm 7.9\%$ , degraded  $30.3 \pm 8.6\%$ , and badland material  $26.6 \pm 9.0\%$ . Although the non-degraded grassland shows one Factor K indicating very low soil erodibility compared to the others and badland material, the aggregate stability data highlights a very fragile environment. Thus, when grassland is impacted by an increment in grazing activity and/or water erosion, it may become easily degraded. These results are key to improve the land management as the study are within a remarkable national park of outstanding ecosystems.

Multiple abiotic and biotic factors (e.g. inter- and intra-species interactions) influence the communities associated with the rhizosphere. Research often only evaluates the impact of drivers on a single taxonomic kingdom, omitting possible inter-kingdom interactions in the rhizosphere. Here, we investigate the communities (i.e., bacteria, fungi, protozoan and metazoan) associated with the rhizosphere of the invasive plant species *Rubus niveus* in three different areas of Santa Cruz Island (Galapagos Islands, Ecuador). At each site, we collected 15 replicates of the rhizosphere of *R. niveus*. The taxonomical diversity was investigated via DNA metabarcoding of the bacterial 16S rRNA gene, fungal ITS2 region and metazoan and protozoa CO1 gene. Conjointly, the soil chemical parameters (e.g. pH, concentration of heavy metals, carbon, nitrogen) were evaluated. Soil biotic and abiotic parameters were integrated through ecological network analyses to reveal the interactions between kingdoms and the influenced abiotic soil parameters.

Our results indicate that bacteria were dominating networks (62-70% of nodes), fungi were the second most abundant kingdom (16-21%), followed by metazoa and protozoa (5-12% and 4-7% respectively). The three networks shared only 46 OTUs (out of 229, 293 and 227 nodes), and no common inter-kingdom interactions nor shared keystone species were found among the three sampling areas. Certain species acted as keystone species within some networks but not in others, while another subset was identified as “unique” to each respective network. The chemical parameters significantly differed among the sites, and their impact on the networks highly varied depending on the sampled site. The soil communities that are associated with the rhizosphere of *R. niveus* were made up of both site-specific and cosmopolitan taxa. Also, the factors that influenced these communities vary across different environments, which highlights the need to study diverse belowground communities to gain a deeper understanding of how biotic and abiotic factors are shaping them.

#### DEVELOPMENT OF FERTILISER FROM BREWERY WASTE: HINTS FROM THE ALGAE BREW PROJECT

N. WARIS <sup>1</sup>, M. COLETTA <sup>1</sup>, M. MONTICELLI <sup>1</sup>, G. CAPRIOLI <sup>2</sup>, M. CESPI <sup>2</sup>, E. VITTADINI <sup>1</sup>, A. LA TERZA <sup>1</sup>

<sup>1</sup> School of Biosciences and Veterinary Medicine, University of Camerino, Via Gentile Ill da Varano, 62032, Camerino, ITALY

<sup>2</sup> School of Pharmaceutical Sciences and Health Products, University of Camerino, Via Madonna delle Carceri Varano, 62032, Camerino, ITALY

The use of mineral fertilizers for crop production is an unsustainable approach, negatively impacting the environment, soil health, and fertility. The AlgaeBrew project addresses these linear economy-based practices by managing brewery waste, which otherwise is fated to become a catalyst for soil, water, and environmental deterioration. AlgaeBrew aims to use brewery wastewater and brewer's spent grains to cultivate *Nannochloropsis* spp. to produce eicosapentaenoic acid (EPA) for aquaculture feed and agricultural fertilizer using the defatted microalgae. For fertilizer production, defatted microalgae were blended with spent coffee grounds (SCG) using 0.5% xanthan gum as a binding agent to produce nine formulations through the wet granulation method. The C/N ratio was estimated for each formulation, and the formulation with 50% defatted microalgae and 50% SCG was finalized (C/N: 11). Phytotoxicity tests were conducted to examine the toxicity of fertilizer by using *Lepidium sativum*, *Sorghum saccharatum*, and *Sinapis alba*. Compared to control OECD soil, in *S. alba*, a higher germination index (GI) was observed for 1.2%, 2.5% and 5% of fertilizer applications. Whereas a higher GI in *L. sativum* was observed for control, 1.25%, 2.5% and 5% of fertilizer application, and in *S. saccharatum*, for 2.5%, 10% and 15% of fertilizer application. These results depict the positive effect of novel fertilizer on GI. Moreover, upon root length analysis, no significant differences were noted in the root length of all tested plant species grown in control soil and lower concentrations of fertilizer. Furthermore, this formulation was also able to increase the water-holding capacity of the soil. As this is an ongoing EU ERA-NETs - SUSFOOD2 project, new fertilizer formulations are being developed using other brewery waste. In the future, ecotoxicological tests involving soil fauna organisms and plant pot experiments will be carried out to assess the fertilizer's effect on plant health and soil rhizosphere microbiome (i.e. bacteria and protists). In conclusion, the AlgaeBrew strives to emphasize on zero-waste generation, circular bio-economy and agricultural sustainability.

<sup>2</sup> Universitat Politècnica de València, Valencia, SPAIN

<sup>3</sup> Universitat Politècnica de València, Valencia, SPAIN

Population growth has led to an increase in urban and industrial waste, which has agronomic potential as a source of fertiliser, organic matter, nitrogen and other plant nutrients.

However, its use is regulated in the European Union by Council Directive 86/278/EEC, partly because of pathogens and their impact on human and soil health. The Council Directive sets a safety period of 10 months from sludge application to crop harvest, which is an obstacle for most horticultural crops and relegates them to rain-fed crops. Pasteurization processes can eliminate pathogenic micro-organisms and can therefore achieve two results: reduction of the safety period and reuse of a residue.

According to that idea, this research aims to use pasteurised sewage sludge in different formats to improve soil quality, increase soil enzymatic activity and demonstrate the elimination of pathogenic microorganisms in a laboratory control experience. A greenhouse experience was carried out with *Capsicum annum* combined with fresh sludge and pasteurised sludge (paste, granule and pellet formats), 3 doses (40, 80 and 120 tonnes per hectare), 2 soil incorporation positions (buried and surface) and 3 replicates for each combination. After the harvest, chemical, biological and microbiological analyses were carried out on the soils.

The main outcomes revealed that the pasteurisation process eliminated *Salmonella* and *Escherichia coli*. In addition, an increase of 1.43% was registered in the organic matter between control and fresh sludge, 1.83% in the case of pasteurised paste, 1.65% with granulate and 1.88% with pellet. An increase between 0.06 and 0.07% was registered in nitrogen content, enzymatic activity also increased with sludge dose, especially for dehydrogenase from 0.52 ml H g<sup>-1</sup>soil in control to 4.73, 5.22, 4.31 and 4.82-ml H g<sup>-1</sup>soil in fresh, paste, granule and pellet sludge respectively, urease activity was also increased in all sludge formats. The addition of sewage sludge to soil improved chemical and biological properties, and pasteurisation eliminates all pathogenic microorganisms contained in sludge.

Soil and weather conditions, alongside to cropping system management practices, influence soil heterotrophic respiration and nitrous oxide emissions in agricultural soils. This network of complex interactions can be evaluated using process-based dynamic simulations models, that represent useful tools to identify trade-off practices to reduce CO<sub>2</sub> and N<sub>2</sub>O soil fluxes.

Continuous field measures of CO<sub>2</sub> and N<sub>2</sub>O soil fluxes were obtained through an automated greenhouse gases (GHG) monitoring station controlling eight flow-through non-steady-state automatic chambers in two cropping systems (4 chambers for each cropping system) in two pilot farm, located in northern and southern Italy. The two cropping systems (a conventional system and an efficient system, employing a decision support system for fertilization and irrigation, that involves legume and cover crops insertion into the crop rotation) were compared through 3-year crop rotations. Additional data (crop biomass, soil mineral nitrogen, soil water content and temperature) from field monitoring have been collected in order to provide a reliable daily prediction of CO<sub>2</sub> and N<sub>2</sub>O emissions from topsoil layers. ARMOSA model (Perego et al., 2013), employed in this study, simulates crop growth, water, C and N dynamics under different pedoclimatic conditions and management practices. It already demonstrated its reliability in reproducing crop yield and in evaluating crop production environmental effects (especially NO<sub>3</sub> leaching) under contrasting pedoclimatic conditions. After parameters calibration, the model was able to satisfactorily capture crop and soil related variables, as well as CO<sub>2</sub> and N<sub>2</sub>O cumulative emissions obtained on the base of soil use. Overall, ARMOSA model adequately simulated emissions trends over time, taking into account weather conditions, tillage events, mineral N application (type and depth), crop residue type and management (removal, soil incorporation or mulching).

### TEMPORAL EVOLUTION OF PHOSPHORUS AVAILABILITY FROM ROOT IRON PLAQUE FOR RICE GROWN UNDER DIFFERENT WATER MANAGEMENT

S. MARTINENGO<sup>1</sup>, M. MARTIN<sup>1</sup>, A. SEYFFERTH<sup>2</sup>, D. SAID-PULLICINO<sup>1</sup>, L. CELI<sup>1</sup>

<sup>1</sup> University of Turin, Department of Agricultural, Forest and Food Sciences, Grugliasco, ITALY

<sup>2</sup> University of Delaware, Department of Plant and Soil Sciences, Newark, UNITED STATES MINOR OUTLYING ISLANDS

The redox cycling of iron (Fe) in paddy soils affects phosphorus (P) cycling, consequently water-saving practices could modify P availability for rice. The changes of Fe plaque dynamics at rhizosphere level may consequently affect P retention, release and plant uptake. Considering the variability in soil P speciation, limited information is available regarding the forms of P retained by Fe plaque and their relationship with P availability for rice. We hypothesized that dry periods during rice cropping will affect porewater chemistry, thus influencing the quantity and mineral composition of plaque. These variations will result in changes in the forms and mechanisms of P retention by the plaque, potentially impacting its role as a sink or source of available P. Rice was cultivated in mesocosms under continuous soil flooding (CF) or alternating wetting and drying (AWD) irrigation. Roots sampled during rice growth were chemically extracted to investigate the temporal evolution of Fe plaque crystallization, while the forms of P retained in the plaque were evaluated by spectroscopic techniques. The results indicated that dry periods led to a decrease of Fe<sup>II</sup> in the solution, in turn increasing its P:Fe molar ratio. AWD resulted in the lower plaque deposition mainly composed of poorly crystalline Fe phases. The FT-IR spectra showed that under AWD the formation of amorphous Fe-P co-precipitates were favored compared to CF systems where surface P sorption on crystalline Fe phases was mainly observed. P-XANES revealed an increase in the retention of organic P forms under AWD, likely due to the higher P:Fe molar ratio favoring co-precipitation over inorganic P forms. Plant-P under AWD better correlated with plaque-P compared to CF, because of the different P retention mechanism. Our findings support the hypothesis that water management influences P availability for plant uptake, because AWD promote the formation of Fe-phosphate precipitates with a faster dissolution rate compared P sorbed on Fe (hydr)oxides, enhancing P availability for rice.

### GENETIC AND FUNCTIONAL DIVERSITY OF BACTERIAL COMMUNITIES STRICTLY ASSOCIATED WITH THE SPORES OF ARBUSCULAR MYCORRHIZAL FUNGI ISOLATED FROM THE RHIZOSPHERE OF AMMOPHILA ARENARIA

A. GRASSI, I. PAGLIARANI, C. CRISTANI, G. CANTINI, F. ROSSI, L. AVIO, M. GIOVANNETTI, A. TURRINI, M. AGNOLUCCI

University of Pisa, Pisa, ITALY

The rhizosphere is a dynamic environment colonized by a wide variety of microorganisms, including arbuscular mycorrhizal fungi (AMF) and bacteria that are strictly associated with their spores and mycelium. They promote plant growth and nutrition, and increase plant tolerance to abiotic stresses by improving plant water and nutrient-use efficiency and plant antioxidant defence systems. The aim of this study was the molecular and functional characterization of bacterial communities strictly associated with AMF spores occurring in the rhizosphere of *Ammophila arenaria* growing in a maritime sand dune system, a drought-stressed and low-fertility environment. Illumina MiSeq analyses of bacteria strictly associated with two *Racocetra* species allowed the identification of 14 Phyla, including Bacillota (66.1%) and Actinomycetota (8.2%). 253 Amplicon Sequence Variants out of 281 included culturable bacteria, most of which known for their plant-growth promoting properties. The bacterial community found in *Racocetra persica* was richer than that of *Racocetra fulgida* and 16 indicator species were found, including some rhizobia and actinobacteria species. Interestingly, two endosymbiotic bacteria of AMF were found. Culture-dependent analyses allowed the isolation in pure culture of 203 and 81 strains from *R. persica* and *R. fulgida* spores, respectively. Interestingly, diverse bacterial communities were associated with the spores of the two AMF, although originated from the same host plants and environmental conditions, showing that each AMF isolate recruits on its spores a different microbiota. Functional analyses showed the ability of many bacterial strains to produce high levels of exopolysaccharides, key compounds for plant drought tolerance, favouring water retention and protecting roots against desiccation. Moreover, different bacterial strains were able to produce a number of plant growth promoting compounds. This work selected the best performing bacterial isolates to be further tested in the formulation of effective microbial consortia and applied as innovative inocula promoting plant growth and resilience under climate change.

The symbiotic relationship between Rhizobium and legumes plays a significant role in biological nitrogen fixation (BNF), offering an economical way to improve soil quality and increase the yields of subsequent crops. These crops are rich in nutrients, including fiber, carbohydrates, B vitamins, and essential minerals like iron, copper, magnesium, zinc, and phosphorus. In this process, nodules form on the roots of legumes, where rhizobia bacteria convert atmospheric nitrogen into usable forms. However, the success of nodulation and nitrogen fixation relies on the mutual compatibility and effectiveness of the Rhizobium-legume partnership, which can vary with different soil and environmental conditions. In our research study for enhancing products yields, we are working on isolation and characterization of PGPR associated on the nodule surfaces and crushed into legume seed effectively improve the nodulation of legume plants under real-world field conditions. Legume plant samples collected from the research field of Ayub Agricultural Research Institute, Faisalabad. The nodules were cut from samples and subjected to PGPR isolation through serial dilution method purified on nutrient agar media followed by the morphological characterization including colony size, colour, texture and Gram's reaction. The isolated strains were analyzed for their ability to promote plant growth, focusing on key characteristics like their capacity to solubilize phosphate, produce indole-3-acetic acid, and to exhibit ACC deaminase activity. In the next phase of our research, a pot experiment will be conducted through complete randomized design to check the effect of inoculation influence of screened bacterial isolates on nodule formation of legume plants. We are expecting the identification of potential PGPR strains with enhancing possible role in legume crops nodule formation, examining the current effectiveness of microbial interventions in soil ecosystems and exploring the potential of advanced bioengineering aiming to enhance soil health and crop production.

This study shows how geodiversity is a key factor of the microbial community diversity in the soils of ancient olive groves. Extreme climate events determine important variations in olive tree activities, but their impact on soil microbial biodiversity is still poorly documented. Eighty soil samples were collected from six different geochemical provinces of Tuscany, Italy. We investigated by metabarcoding sequencing, the phylogenetic and functional profile of soil bacteria in ancient Tuscany olive groves cultivated in areas named as Protected Designation of Origin (PDO) and Protected Geographical Indication (PGI). Lithological geodiversity factors of soils were assessed by using the rare earth elements (REEs), the latter considered as fingerprints of the sediments origin and monitors of environmental variations (e.g. soil erosion processes, plant uptake and related soil nutrient depletion, nutrient biolifting). Soil bacterial diversity, shaped by soil-forming factors such as bedrock degradation, weather changes and microclimate, was assessed by 16S rDNA NG Sequencing.

To date, little is known about the biogeochemical processes related to the absorption and translocation of REEs especially in the olive tree and their relationship with microbial activities.

We showed that REEs fractionation patterns in soil were major drivers for bacterial communities, with a significant influence also by soil hydrologic characteristics. In fact, evidence from phylogenetic and environmental data support the existence of an evolutionary group that appears to possess important adaptations such as resistance to environmental hazards. Our study, for the first time, explored the relationship between REEs and soil microbiome under natural olive tree growing conditions in a large variety of geochemical environments. Moreover, it provides new environmental implications for the definition of soil quality.

#### Funding information

Financial support provided by Rural Development 2014-2020 program of Tuscany Region, through the Projects GeOEVO WEB GIS "A geospatial framework to support integrated biogeochemical modelling of the Tuscany olive grove and olive oil traceability context" and MONITOIL "Monitoring olive ripening for oil production: rapid methods compared".

Plant roots modulate functional traits of the rhizosphere microbial community, which process and transform organic matter in soil. How root morphology and soil texture affect functional traits through altered microbial activity remains uncertain. To address this question, two maize genotypes with contrasting root morphology - a mutant deficient in root-hairs, rth3, and its wild-type sibling, WT, were grown 5 consecutive years in excavated plots filled with two homogenized soil substrates - loam and sand. Soil sampling was performed annually at the plant growth stage of BBCH19, corresponding to vegetative growth. Soil was excavated from the first 20 cm depth and roots, separated from bulk soil, brushed for rhizosphere collection. We hypothesized (H1) larger increase in carbon content in loam than sand bulk soil due to greater CO<sub>2</sub> losses in sand related to better aeration and lower water retention in soil pores; and (H2) increased enzyme affinities to substrates in the rhizosphere over the years due to microbial adaptation producing specific enzyme systems. Despite the positive trend in general, a significant 19 % increase in bulk soil C content was detected solely under rth3 in loam. In contrast to C supply, remarkable increase in N content of 7 and 41 % in loam, and 62 and 82 % in sand, for WT and rth3, respectively, was observed. This resulted in lower C:N ratio in sand than loam soils, accompanied by slower microbial specific growth rate ( $\mu_{max}$ ), smaller microbial C pool, and lower maximum enzymatic rates for  $\beta$ -glucosidase, N-acetylglucosaminidase, leucine aminopeptidase, and acid phosphatase, in the former. Enzyme affinities in the rhizosphere increased in all treatments over the years for  $\beta$ -glucosidase, N-acetylglucosaminidase, and acid phosphatase, which confirmed our hypothesis. Respiration-to-biomass ratio was essentially higher in sand than loam bulk soil, resulting in larger CO<sub>2</sub>-C losses per unit of microbial C in the former. Concluding, changes over the years occurred differently for sand and loam, marginally affected by the presence of root hairs.

#### Body

Climate change poses challenges to global agriculture, affecting both crop production and food security. While models predict climate effects on crop yields the impact of climate change on the fate of nutrients and contaminants within the soil-plant system and the potential consequences for crop quality remain understudied.

Here, we investigate the impact of climate change on heavy metal accumulation by spinach (*Spinacia oleracea*), chosen as a model plant for leafy crops. Spinach is recognized as a significant source of essential micronutrients like iron (Fe), zinc (Zn), manganese (Mn) and magnesium (Mg) yet it also accumulates the non-essential element cadmium (Cd), even up to toxic levels in edible parts. Four spinach varieties were cultivated in soils with diverse geochemistry and heavy metal contents under ambient climatic conditions (20°C daytime temperature, ambient atmospheric CO<sub>2</sub> and 50% water holding capacity) and anticipated future climatic conditions (+2.25°C, +290 ppmv CO<sub>2</sub>, and 7% less gravimetric water content).

Three out of four spinach varieties yielded significantly more edible biomass under future compared to present climatic conditions. Alongside the increase in biomass, significant higher Cd concentrations were found in the edible parts of all spinach varieties under future climatic conditions. Factors such as element partitioning from soil particle to soil solution, soil-to-root transfer and root-to-shoot translocation suggest that the increase in shoot Cd was not caused by changes in the physiological plant traits, but by increased Cd bioavailability in the soil, allowing more Cd to pass the soil-root boundary. Comparative analysis with micronutrients (Fe, Zn, Mn, Mg) showed a similar pattern of increase in metal concentrations in the edible parts of spinach under climate change, but these patterns were overall less consistent and showed lower statistical significance than for Cd.

Our findings provide insights into future spinach production and quality, possibly transferable to other leafy vegetables, and emphasize the importance of considering soil contaminants when investigating climate change impacts on human food security.

Grasslands play a crucial role in providing food, fuel, and fibre, while also serving as significant carbon reservoirs globally. However, they face pressures from intensive management practices and the ongoing impact of climate change. The interplay between these factors and their effects on carbon and nitrogen cycling in grassland soil, along with resulting CO<sub>2</sub> emissions, remains uncertain. The presence of roots and/or mycelia in grassland soil is essential for regulating ecosystem functions and likely plays a significant role in determining how CO<sub>2</sub> responds to global changes. This study aimed to examine how climate warming and grassland management practices interact to influence soil respiration originating from roots, rhizosphere, mycelia, and free-living microbes. We utilised an in-growth core method to partition below-ground respiration. The experiment, designed in a fully-randomised way, assessed the combined effects of warming, nitrogen addition, above-ground biomass removal, and below-ground biotic compartments on CO<sub>2</sub> emissions, as well as carbon and nitrogen pools in grassland ecosystems. Our findings revealed that basal respiration was the highest, followed by respiration from mycelia and roots across all treatments. Interactive treatments demonstrated an antagonistic interaction between warming and nitrogen, which reduced root respiration. These results underscore the importance of understanding the mechanistic processes driving differences in carbon and nitrogen cycling among below-ground components. Moreover, they highlight how interactions between climate change and grassland management practices may either exacerbate or mitigate the effects on soil below-ground respiration.

**Keywords:** grassland ecosystem, autotrophic and heterotrophic, CO<sub>2</sub> emissions, interactive effects, warming

### STRONGER EFFECTS OF MAIZE RHIZOSPHERE THAN PHOSPHORUS FERTILIZATION ON PHOSPHATASE ACTIVITY AND PHOSPHORUS-MINERALIZING-RELATED BACTERIA IN ACIDIC SOILS

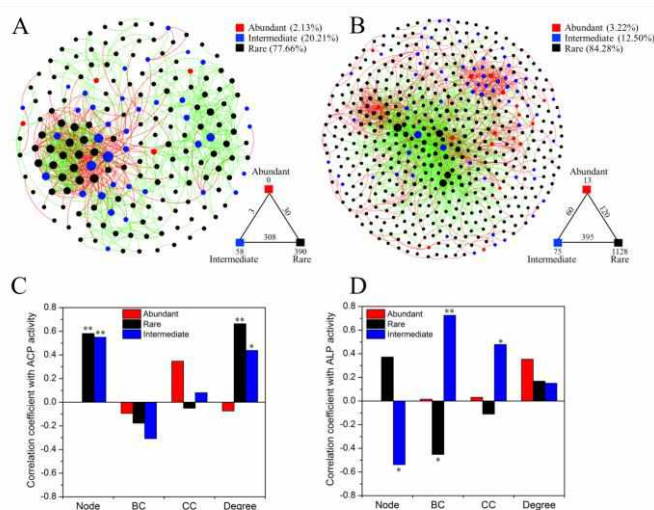

T. FENG

<sup>1</sup> State Key Laboratory of Soil and Sustainable Agriculture, Institute of Soil Science, Chinese Academy of Sciences, Nanjing, #20013;#22269;

<sup>2</sup> University of Chinese Academy of Sciences, Beijing, #20013;#22269;

<sup>3</sup> Helmholtz Centre for environmental Research, Leipzig, #24503;#22269;

Phosphorus (P) is a major limiting nutrient for crop growth in many agroecosystems. Phosphorus-solubilizing microorganisms (PSM) mineralize soil Po mainly through secreting P-mineralizing-related enzymes such as acid phosphatase (ACP) and alkaline phosphatase (ALP). However, the different responses of phoC and phoD-harboring bacterial community to fertilization strategies need to be clear. In addition, the similar research has not been conducted in phoC-harboring bacteria, and the contribution of rare phoC-harboring bacteria to the ACP activity is still unclear. Therefore, we performed a long-term experiment that included organic manure and mineral fertilizer treatments at the same nutrient input level in the North China Plain and determined soil phosphatase activity and phoC- and phoD-harboring bacterial subcommunities. The results showed that relative to bulk soils, rhizosphere showed higher ACP and ALP activities and phoC and phoD gene abundance, but this effect strength was reduced under HP treatment, except for phoC gene abundance. The rhizosphere effect increased diversity of phoC-harboring bacteria under P fertilization but reduced phoD-harboring bacterial -diversity under PO and LP treatments. The rhizosphere significantly influenced phoC- and phoD-harboring bacterial community compositions, with stronger effect on phoD-harboring bacteria; while P fertilization only affected phoD-harboring bacteria. Immigrated and extinct species play important roles in reshaping phoC- and phoD-harboring bacterial communities, respectively, in response to the rhizosphere effect. Overall, compared with P fertilization, the maize rhizosphere more strongly influenced soil phosphatase activities, phoC- and phoD-harboring bacterial communities in acidic soils, with phoD-harboring bacteria responding more strongly to the rhizosphere effect and P fertilization. Notably, the strength of the rhizosphere effect heavily relied on P fertilization level.

<sup>3</sup> Cultivating New Frontiers in Agriculture (CNFA) Georgia, Tbilisi, GEORGIA

Georgia is distinguished by a very interesting soil cover dominated by mountain-meadow soils with the landscape-geographical nominations listed in the national classification system. During the last decades, the works toward implementation of WRB classification system were intensified in Georgia, which revealed certain characteristics of some soil types not being properly documented and interpreted before due to a lack of analytical techniques and/or field description methodology. The current study describes one of the characteristics found in mountain-meadow soils with humus-illuvial horizons found in the highlands of Georgia. The mountain-meadow humus-illuvial soils occupy a relatively small area in subalpine and alpine zones on the Great Caucasian chain, therefore only four soil profiles with similar properties were identified. Those profiles are distinguished by the participation of humus-illuvial horizon - Bh in their construction. Humus-illuvial horizons start at a 35 cm depth from the surface and are characterized by dark reddish or dark brown colour (5 YR 2.5/2 and 7.5 YR 2.5/2). Humus-illuvial soils have acidic and weakly acidic reactions, horizons are rich in humus and its content is maintained through a depth of a profile. These soils are unsaturated with bases and have a heavy loamy texture. Those properties closely correlate with Sombric horizon properties given in FAO/WRB guideline for soil description. Due to limited data, there is a need for further studies to confirm the existence of Sombric properties in similar soil types spread in mountainous areas of Georgia, which will support advancement in soil classification both at the national and international levels.

#### CHARACTERIZATION OF SOILS ON TOP OF MORAIN HILLS IN THE SOUTH-EAST PART OF LATVIA.

B. BUSA, J. ...A. LEVKOVŠ, I. ERDBERGA

Latvia University of Life Sciences and Technologies, Jelgava, LATVIA

Three soil profiles were created in the Dagda hill area, subjectively in the highest relief areas, where the feasibility study revealed three different soil texture classes, respectively N 56°05'170'' E 27°19'124''; 187 m above sea level, N 56°05'218'' E 27°17'097''; 175 m above sea level and N 56°05'240'' E 27°16'137''; 180 m above sea level. In the first soil profile, sandy texture dominates, in the second, sandy loam is found, and in the third, respectively, clay. Although geologic Quaternary sediment maps show moraine sediments throughout this area, they are found only in the second profile. The first soil profile shows the influence of the stream and shows sorted material. The third profile shows glaciolimnic sediments. Although all the studied soils are located on relief elevations and have been cultivated, no erosion has been observed in any case. During the study, in addition to the analyzes required for WRB classification, analyzes of soil infiltration and moisture capacity have been performed. This was done with the aim of finding out the reason why plants sown at the same time have different germination abilities.

### MANGANESE CYCLING IN EUROPEAN FORESTS TO CONTROL SOIL ORGANIC MATTER

R. DUQUENNE, M. HERPOEL, P. BOGAERT, P. DELMELLE, Y. AGNAN

Earth and Life Institute/UCLouvain, Louvain la Neuve, BELGIUM

Manganese (Mn) plays a key role in soil organic matter dynamics, through stabilization or destabilization reactions. Yet, it has been shown that Mn is one of the most intensively recycled elements by vegetation in forest ecosystems through litterfall (dead leaves falling to the soil) and throughfall (rain water that percolates through the canopy), much more than iron or aluminum. An accurate quantification of Mn fluxes inside the ecosystem is therefore required to better assess the soil organic matter dynamics. In this context, we propose to quantify the influence of environmental variables on Mn fluxes in forest ecosystems. For this purpose, we used the European ICP Forests database that consists in a large environmental data set in forest ecosystems, including periodic measurements on atmospheric deposition, litterfall, and soil solution. We considered 500 sampling plots in Europe from early 1990's to 2018. Annual Mn fluxes were calculated for each main tree species. In parallel, additional environmental variables were included in the analysis, such as climate and soil, using international databases (Copernicus and LUCAS, respectively). The data were processed using a generalized linear model (GLM). Interestingly, litterfall and throughfall fluxes were correlated together for each tree species. Results showed that the GLM predicted 50% of the variance of the actual Mn fluxes. Alongside climate and soil parameters, tree species was an important factor in controlling the Mn throughfall fluxes. The expected modifications in tree species distribution with forest management and climate change will thus likely influence soil organic matter dynamics in forest ecosystems.

### ARGAN TREE AS A POTENTIAL MODEL SPECIES FOR REFORESTATION: IMPACTS ON SOM AND MICROBIAL COMMUNITIES.

M. PATIÑO GARCÍA <sup>1</sup>, J. SILES <sup>1</sup>, P. MARTÍNEZ-GÓMEZ <sup>2</sup>, M. RUBIO <sup>2</sup>, F. BASTIDA <sup>1</sup>

<sup>1</sup> CEBAS-CSIC (Department of Water and Soil Conservation), Murcia, SPAIN

<sup>2</sup> CEBAS-CSIC (Department of Plant Breeding), Murcia, SPAIN

Argan tree (*Argania spinose* L.) is common in arid and semi-arid zones of the Moroccan sub-Saharan region and is adapted to resist periods of drought (less than 250 mm per year) and extreme temperatures. In the context of climate change, these characteristics could make argan tree a candidate model for afforestation on marginal, degraded lands in other semiarid areas where this plant species is not yet present. The suitability of this tree for reforestation strategies will depend on its impact on SOM composition and soil microbial communities, among others. In this study, we evaluated physicochemical characteristics, nutrient contents, molecular composition of SOM (analytical pyrolysis and thermogravimetry) and activity and abundance of microbial communities in soil under Spanish ecotypes of argan trees in comparison with that under pine trees and bare soil in a semi-arid region of southeast Spain. Our preliminary results indicate increased SOM and nutrient (carbon, nitrogen, phosphorous, etc.) contents detected in soils under influence of argan where not different from those influenced by pine. Thermal analysis showed that the two types of vegetal cover enriched soil with SOM of intermediate recalcitrance in the same proportions respect to the bare soil. The pyrolytic behavior of SOM under argan and pine showed to be of a wider functional variety. Increased bacterial and fungal abundances and enzyme activities ( $\beta$ -glucosidase, alkaline phosphatase, urease) were found in soil from argan respect to the bare soil, but differences respect to the soil under pine trees where not detected. Instead, the fatty acid-based structure of microbial communities did change between soils influenced by argan and pine. Further insights into these differences will be obtained by functionally and taxonomically characterizing microbial communities through metagenomics. Our preliminary results seem to indicate that the impact of reforestation with argan on SOM characteristics and microbial communities is similar to that of pine.

#### TREE SPECIES LITTER QUALITY EFFECTS ON C SEQUESTRATION AND STABILITY IN SANDY FORESTS SOILS IN THE NETHERLANDS AND BELGIUM

S. NIJDAM<sup>1</sup>, E. DESIE<sup>1</sup>, L. VAN DEN BERG<sup>3</sup>, M. DE GRAAF<sup>3</sup>, W.E. MORRIËN<sup>2</sup>, B. JANSEN<sup>2</sup>, K. VANCAMPENHOUT<sup>1</sup>

<sup>3</sup> Bosgroep Zuid Nederland, Heeze, THE NETHERLANDS

Elevated atmospheric CO<sub>2</sub> levels contribute to climate change, posing a threat to ecosystems. Forest soils, rich in carbon (C), offer potential as C sinks to mitigate climate change. However, there is limited understanding regarding the influence of tree species composition on C stability. Therefore, the objective of this study is to identify the effect of tree species composition on C sequestration and stability in sandy soils within the Netherlands and Belgium.

We hypothesize that the input of organic matter (OM) plays a key role in influencing soil OM decomposition rates, thereby impacting soil pH and in the long term (decadal) stabilisation of C. Litter quality can be categorized as high (rich) or low (poor), which influences dominating decomposers and nutrient cycling. Twin-plots within a forest conversion trial in The Netherlands and Belgium with poor and rich litter quality forest stands were identified. Composite samples of the topsoil (0-10cm) and subsoil (10-20cm) have been analysed for soil physicochemical parameters, C and nitrogen content and C stocks. Additionally, soil fractionation into the particulate OM fraction and the mineral associated OM fraction provides insight in C stabilisation mechanisms. Together with molecular characterisation of the OM using Pyrolysis-GC/MS and data on soil biodiversity, a wide set of parameters is obtained to provide a comprehensive overview of soil C dynamics. Preliminary findings indicate distinct differences in molecular compositions between the rich and poor litter quality stands in the topsoil, highlighting differences in degradable and aromatic components. Poor litter stands show higher abundances of aliphatics and lignins, while rich litter stands show relative enrichment of polysaccharides and nitrogen-containing components, suggesting diverse OM inputs and distinct degradation pathways and C stabilisation mechanisms. This ongoing experiment enhances our understanding of the interplay among tree species composition, litter quality, and soil C dynamics, providing valuable insights for sustainable forest management practices aimed at climate change mitigation.

### STOCKS OF ORGANIC CARBON (SOC) IN SLOVENIAN FOREST SOILS – FIRST RESULTS OF THE FOREST SOIL SURVEY 2022-2023

A. MARINSEK <sup>1</sup>, D. ZLINDRA <sup>1</sup>, E. KOZAMERNIK <sup>1</sup>, B. MALI <sup>1</sup>, P. HORVAT <sup>1</sup>, E. ZAGORAC <sup>2</sup>, N. MESAREC <sup>2</sup>, J. BERGANT <sup>2</sup>, B. VRSCAJ <sup>2</sup>, P. SIMONCIC <sup>1</sup>

<sup>1</sup> SLOVENIAN FORESTRY INSTITUTE, LJUBLJANA, SLOVENIA

<sup>2</sup> AGRICULTURAL INSTITUTE OF SLOVENIA, LJUBLJANA, SLOVENIA

In the years 2022 and 2023, we sampled forest soils on 200 plots throughout Slovenia. The basis for the selection of sampling sites was subsample of a grid of 2 x 2 km. The plots were selected according to the most important forest soil types in Slovenia. The main task was to determine the amount of SOC content in the organic and mineral layers of the forest soils.

To determine the carbon storage, sampling was performed to a depth of 40 cm. The organic horizons were sampled using a wooden frame (25 x 25 cm). The samples of the mineral part of the soil were taken with a metal soil sampling probe with an inner diameter of 6.7 cm. Mineral part of the soil were sampled individually in steps of 10 cm till the depth of 40 cm. Due to the heterogeneity of the forest soil, all samples were taken from five locations in each plot. After, the composite sample was made, presenting each sub-horizon or soil depth, prepared for the physical and chemical analysis.

Forest soils are characterized by high variability of soil properties and consequently carbon storage. Therefore, the estimation of the skeleton content in the soil has an important impact on the calculation of mineral carbon stocks in the soil, especially on sites with calcareous substrates.

Based on 1022 soil samples, we obtained results for the SOC content in the soil expressed in t/ha. Differences in the average SOC stock between the individual soil types are considerable (Table 1). The individual minimum (2.11 t/ha) and maximum values (167.15 t/ha) also indicate even greater differences within the individual plots.

After additional analysis and verification, part of the data will be used for the assessment of carbon storage in mineral forest soils and litter in the reporting process for the LULUCF sector.

Table 1: Basic statistical parameters that provide values for the SOC content in different forest soil types (organic horizons and mineral part up to 40 cm depth together).

SOIL TYPE	N plots	AVG (t/ha)	Min (t/ha)	Max (t/ha)	Med (t/ha)	SD	CV
Dystric brown soils / Dystric Cambisols	46	86.7	35.6	151.01	86.92	31.24	36.03
Eutric brown soils / Eutric Cambisols	18	76.83	11.52	127.45	80.97	27.28	35.51
Hypogley / Gleysols	1	131.43	131.43	131.43	131.43	NA	NA
Leached soils / Luvisols	5	81.84	46.76	123.16	86.37	28.73	35.1
Alluvial soils / Fluvisols	6	78.71	3.33	143.99	88.37	48.55	61.69
Pseudogley / Planosols	6	95.99	65.88	167.15	81.84	38.81	40.43

### COMPOSITION OF DOM ALONG DEPTH GRADIENTS IN PADDY FIELDS TREATED WITH CROP STRAW FOR 10 YEARS

H. RONG <sup>1</sup>, T. JIANG <sup>2</sup>, J. LIU <sup>1</sup>, B. LI <sup>1</sup>, C. WANG <sup>1</sup>

<sup>1</sup> College of Resources, Sichuan Agricultural University, Chengdu, CHINA

<sup>2</sup> College of Resources and Environment, Southwest University, Chongqing, CHINA

Crop straw return is a widely used agricultural management practice. The addition of crop straw significantly alters the pool of dissolved organic matter (DOM) in agricultural soils and plays a pivotal role in the global carbon (C) cycle, which is sensitive to climate change. The DOM concentration and composition at different soil depths could regulate the turnover and further storage of organic C in terrestrial systems. However, it is still unclear how crop straw return could influence the change in DOM composition in rice paddy soils. Therefore, a field experiment was conducted in which paddy soil was amended with crop straw for 10 years. Two crop straw-addition treatments [NPK with 50% crop straw (NPK+1/2S) and NPK with 100% crop straw (NPK+S)], a conventional mineral fertilization control (NPK) and a non-fertilized control were included. Topsoil (0–20 cm) and subsoil (20–40 cm) samples were collected to investigate the soil DOM concentration and compositional structure of the profile. Soil nutrients, iron (Fe) fraction, microbial biomass carbon (MBC), and concentration and optical properties (UV–Vis and fluorescence spectra) of soil DOM were determined. Here, we found that the DOM in the topsoil was more humified than that in the subsoil. The addition of crop straw further decreased the humification degree of DOM in the subsoil. In crop straw-amended topsoil, microbial decomposition controlled the composition of DOM and induced the formation of aromatic DOM. In the straw-treated subsoil, selective adsorption by poorly crystalline Fe(oxyhydr)oxides and microbial decomposition controlled the composition of DOM. In particular, the formation of protein-like compounds could have played a significant role in the microbial degradation of DOM in the subsoil. Overall, this work conducted a case study within long-term agricultural management to understand the changes in DOM composition along the soil profile, which would be further helpful for evaluating C cycling in agricultural ecosystems

#### EFFECT OF SHEEP WOOL PELLETS ON NITROGEN UPTAKE BY PLANTS DEPENDING ON THE ORGANIC MATTER CONTENT AND BIOLOGICAL ACTIVITY OF SOIL

F. KOVAC, E. PAPDI, A. VERES, J. KATALIN

Department of Agro-Environmental Studies, Hungarian University of Agriculture and Life Sciences, Budapest, HUNGARY

The adaptation of recycling and advanced techniques is crucial for the establishment of a sustainable agriculture that is not reliant on artificial fertilizers. Pellets made from waste sheep wool have emerged in recent years as a prospective substitute for nutrient replenishment in horticultural production. However, little information is available on the impact of wool pellets on soil biological activity and plant nutrition. Hence, it can be assumed that wool pellets can influence the microbiological activity in the soil depending on soil organic matter content. In this study, we investigated the effect of wool pellets on permanganate-oxidizable carbon content, fluorescein diacetate activity and  $\beta$ -glucosidase activity in two sandy soils with different organic matter contents in a pot experiment. We also examined the influence of wool pellets on the nitrogen content of both soil and pepper plants, as well as on the photosynthetic pigments, gas exchange intensity, and growth parameters of the plants. Results show that treatments with wool pellets increased soil biological activity in both soil types. Wool pellets significantly increased soil and plant nitrogen content and improved plant physiological parameters compared to untreated control. Moreover, wool pellets significantly increased plant biomass in both soil types, but was higher in the low soil organic matter content soil type due to faster mineralization rate and higher air capacity. In the case of higher soil organic matter content, higher yields were observed with the wool pellet treatment, due to slower and more progressive decomposition and nitrogen supply of the wool pellets. These results suggest that wool pellets are an important source of nitrogen for plants and that their biological effect plays a key role in enhancing soil biological activity, but this effect is highly dependent on the intensity of mineralization and decomposition in the soil.

<sup>4</sup> University of Nyíregyháza, Institute of Environmental Science, Nyíregyháza, HUNGARY

SOM is found in soil in different forms, qualities, with different properties, functions and decomposition rate. During our experiments, we analyzed the soils of organic matter (OM) manipulation plots set up under open field conditions on the Luvisols soil of a deciduous forest in Hungary. In “Detritus Input and Removal Treatments” experiment we used Double Litter, Double Wood, Control, No Litter, No Roots, and No Input manipulations. The aim of our research was to compare the effects of long-term removal and addition of OM on different soil properties. We investigated the changes in glomalin related soil protein content, Active carbon (POXC), SOC and biological activity with the help of DHA GLU enzymes. 24 years after the beginning of the treatments, the SOC content of the soil in the DL treatment showed a significantly higher value (21%) than in the litter removal treatments. POXC content is the portion of SOM that is easily accessible to microbes. Therefore, it is reliable indicator of microbial degradation processes and soil health. In the long term, we measured a significantly higher value of this carbon fraction in the DL treatment than in any treatment without litter. We showed similarly higher values for the Co and DW plots than for the treatments without surface litter. In terms of biological activity, the Co and DL showed significantly higher activity than withdrawal treatments. In case of the glomalin content, we can show a similar trend as the POXC content; treatments without surface litter were significantly different from the other treatments. Overall, it can be determined whether the decrease in OM entering the soil had a greater impact on the decomposition and transformation processes taking place in the soil, SOM dynamics, than the increase in the amount of OM. In the future, it is important to explore the relationship between glomalin and the soil to find the connections between glomalin formation and the carbon storage capacity of the soil.

#### EVALUATION OF AGRICULTURAL PRACTICES FOR MITIGATING CLIMATE CHANGE ON RAIN-FED SOILS IN THE MEDITERRANEAN REGION

C. PEREZ SIRVENT <sup>1</sup>, M.J. MARTINEZ SANCHEZ <sup>1</sup>, S. MARTINEZ LOPEZ <sup>1</sup>, L.B. MARTINEZ MARTINEZ <sup>1</sup>, I. EL HAMAOU <sup>1</sup>, M. HERNANDEZ CORDOBA <sup>2</sup>, J. BECH <sup>4</sup>, M.L. TUDELA <sup>3</sup>, J. MOLINA RUIZ <sup>3</sup>

<sup>1</sup> University of Murcia. Dep. Agricultural Chemistry, Geology and Pedology, Murcia, SPAIN

<sup>2</sup> University of Murcia. Dep. Analytical Chemistry, Murcia, SPAIN

<sup>3</sup> University of Murcia. Dep. Geography, Murcia, SPAIN

<sup>4</sup> University of Barcelona, Barcelona, SPAIN

In the face of climate change, management strategies should focus on techniques that can mitigate negative effects and meet society's demands for environmental protection, food security for a growing population and rural-urban migration.

In Mediterranean soils, increased soil fertilisation is necessary due to the generally already low levels of organic matter. Increasing restrictions on inorganic fertilisation mean that organic fertilisers must be used to achieve the required increase. However, this can lead to higher operating costs and uncertainty about the economic viability of farms. Implementing mitigation and adaptation measures in rainfed agriculture can result in increased soil fertility, CO<sub>2</sub> sequestration, improved water infiltration and reduced soil erosion.

Implementing mitigation measures based on the 4 per thousand initiative can improve and conserve soil resources, promote organic farming through the use of local waste, and encourage a circular economy, which can help reduce rural exodus and increase fertility, leading to greater prosperity.

A baseline has been established to define the initial state of the monitored areas, which has allowed the calculation of different indicators and the real costs of improving soil ecosystem services. It can be concluded that measures to add organic matter to the soil increase soil fertility and do not cause phytotoxicity problems. These measures meet the objectives proposed in the Green Pact, moving towards soil neutrality and increasing the ecosystem services it provides.

As part of the LIFE AMDRYC4 project, the use of green manure, the provision of locally sourced composted plant material, the use of plant waste, compost management and crop rotation were identified and monitored on four plots as measures to improve soil fertility in the Region of Murcia. Implementing good agricultural practices, including adding organic matter to the soil and restoring natural vegetation, can improve biodiversity and soil quality, thereby slowing desertification and contributing to Initiative 4‰. The effectiveness of these proposals has been assessed using indicators such as the DESERTNET fertility, salinity and phytotoxicity indicators.

#### SOIL NITROGEN AND CARBON POOLS UNDER ALDER, BIRCH AND SPRUCE CANOPIES IN SPRUCE-DOMINATED MIXED STANDS

P. SORONEN<sup>1</sup>, S. JÄMTGÅRD<sup>2</sup>, M. MYLLYMÄKI<sup>3</sup>, A. SMOLANDER<sup>1</sup>

<sup>1</sup> Natural Resources Institute Finland (Luke) - Natural resources / Soil ecosystems, Helsinki, FINLAND

<sup>2</sup> Swedish University of Agricultural Sciences (SLU) - Department of Forest Ecology and Management, Umeå, SWEDEN

<sup>3</sup> Natural Resources Institute Finland (Luke) - Bioeconomy and environment / Forest inventory and planning, Helsinki, FINLAND

Tree species is one of the key determinants of the quality and quantity of soil organic matter in forests. Spruce produces recalcitrant litter, thus lowering nutrient availability and increasing forest floor carbon (C) stock, whereas broadleaved trees may have potential to enhance soil organic carbon (SOC) accumulation to mineral soil. We studied how grey alder, having symbiosis with N<sub>2</sub>-fixing Frankia, and birch affect soil nitrogen (N) and carbon pools and organic matter characteristics in spruce stands.

Our study sites, located in Southern Finland, were three 40-60-year-old Norway spruce -dominated stands with grey alder and birch (silver birch and downy birch) as admixture and a 20-year-old spruce-dominated stand with only alder as an admixture. Applying the Finnish forest type classification, the two 60-year-old stands represented a relatively fertile Oxalis–myrtillus type (OMT), and the two younger sites represented less fertile Myrtillus type (MT). We took the soil samples from forest floor and 0-10 cm mineral soil at 50-100 cm distance from 3-8 trees of each tree species and analysed SOC and total N stocks. Induced diffusive fluxes of plant-available N forms were determined using microdialysis technique in situ.

We found significantly higher N stock of forest floor under the canopy of alder, as compared to birch or spruce. C:N-ratio of both forest floor and mineral soil was lower under alder versus spruce. In the 60 yr. OMT sites, tendencies for differences between the tree species were observed in microbial biomass N content (alder < birch), microbial biomass C:N-ratio (birch < spruce), C mineralisation rate (alder < spruce), and dissolved organic C content (alder, birch < spruce).

Alder affected soil properties of the spruce stands more strongly than birch, but against our hypothesis, SOC stocks or N fluxes were not significantly affected. In conclusion, the situation in mixed forest is complex, as the spatial distribution of litter and roots reduces the differences between the tree species.

#### SUBAQUEOUS SOIL RESEARCH AT THE LOW SLOVENIAN COAST OF THE ADRIATIC SEA

##### Authors

B. REPE, A. PRISOTVSEK, T. PAVLIN

Geography department, Faculty of Arts, University of Ljubljana, Ljubljana, SLOVENIA

In Slovenia and generally around the world, the topic of subaqueous soils is still poorly investigated. In the case of subaqueous soils in Slovenia, there are only two studies. Both study areas are located exactly at the intersection of two provincial plains in Slovenia. The sea part is represented by the Slovenian part of the Adriatic Sea, the land part by Submediterranean Slovenia. We took a look at the soil forming factors and processes that are important for the development of subaqueous soils. The Slovenian Sea is characterised by low transparency, the shallow water depth and the high nutrient and plankton load. All this fine material accumulates on the bottom and forms the basis for the formation of the seabed. The waves with its force are generated by strong local winds (e.g. the Bora wind) and can seriously disturb the accumulated underwater bottom material. The investigated part of the coastline consists entirely of flysch. The Slovenian coast belongs to the Rias coastal type, where rivers and streams carry material into the bays and form coastal plains. The parent material, water depth and movement, existing vegetation and time play the most important role in the formation of subaqueous soils in this area. The main focus of subaqueous soils research has been to determine the relationship between soil properties (i.e. soil types) and the degree of seawater influence (length of tidal water duration and type of water movement). One sampling site is located on land but is strongly influenced by marine groundwater, two sites are under the influence of tidal water (partially exposed to atmospheric air) and four sites are completely submerged throughout the day and year. All soils were found to be very young and poorly developed. The soil samples were classified according to the WRB classification. Directly above and below the shoreline, different soil types were discovered, namely a Solonchak, Histosol, Gleysol, Arenosol and Leptosol, which form a soil hydrosequence.

#### INFLUENCE OF PEDOGENESIS ON SUCCESSION IN PINE FORESTS

I. ERDBERGA, A. JANSONE B. BUSA, I. STRAUPE

Latvia University of Life Sciences and Technologies, Jelgava, LATVIA

Four soil profiles were created with the aim of clarifying the peculiarities of pedogenesis in Cladinoso-callunosa and Vacciniosa forests. In each forest type, two profiles were created at the highest and two at the lowest points of the local terrain. These soil profiles lie on sand sediments of glaciolimnic origin, which formed inner dunes after the retreat of glacial water. Soil profiles were created respectively at N 57°38'521'' E 25°51'563''; 70 m above sea level, N 57°38'500'' E 25°51'586''; 65 m above sea level, N 57°38'515'' E 25°51'545''; 66 m above sea level and N 57°38'451'' E 25°52'010''; 63 m above sea level. In all soil profiles, podzolization can be observed, as well as an increasing amount of organic matter and a decrease in soil pH as the succession from Cladinoso-callunosa to Vacciniosa intensifies. The following soils were found in the soil profiles: Dystric Arenosol (Claric, Cordic, Humic, Nechic, Aeoli-novic, Pyric); Albic Rustic Ortsteinic Podzol (Arenic, Epic, Oxyaquic, Placic); Dystric Arenosol (Claric, Humic, Nechic, Oxyaquic); Hemic Folic Histosol (Dystric).

Although conservation tillage (CT) versus mechanized tillage (MT) has been extensively studied in soil science, some aspects are still not understood. In particular, a microscale soil aggregation and porosity and their correlation with penetration and infiltration, essential for soil management (Stoops, 2010). The objectives were to evaluate in situ changes in soil structure with different tillage systems, porosity data, infiltration rate (Ir) and penetration resistance (Pr) regarding time. Six treatments were selected: four corresponding to CT, established on *Opuntia* sp. for 5, 7, 8 and 11 years, with irrigation and organic fertilization; one with MT for corn, and one on natural soil (N). At each site, undisturbed soil samples were taken at various depths (0-10 and 10-20 cm), producing mosaics (91 images, 2.5  $\mu$ m pixel size, in 3147 mm<sup>2</sup> on average) by thin section (Ts), quantifying ultramicropore, micropore and mesopore (Gutiérrez-Castorena et al., 2018), in addition to infiltration rates (Bouwer, 1961) and (Pr). Transmission and storage pores predominate, in soil N, and decrease from 16% to 7% and from 50% to 26%, respectively, while structural pores increase from 34% to 67%. In the LM system, there is an inverse relationship from 15 to 35% and from 7 to 19%, respectively, with a decrease in structural pores from 78% to 55%. While in LC, the values varied during the seven years, with values averaging 35%, 15% and 50%, respectively. The Ir value for N was 6.7 cm/hr (11 years), in LC it was 8.5 cm/hr, and finally in LM it was 3.5 cm/hr of water infiltration rate. The column was 245 mm, 273 mm and 137 mm, respectively, in a time of 170 min. When correlating Ir with Pr during the dry period, they reported resistance between 225 and 300 psi, and in the wet period between 125 and 210 psi. In conclusion, soils with LC will reach hydrophysical properties similar to Natural between 5 and 7 years after disturbance.

### STUDY THRESHOLD BETWEEN MACROMETRY AND MICROMETRY IN IN SITU DIGITAL MICROPHOTOMOSAIC.

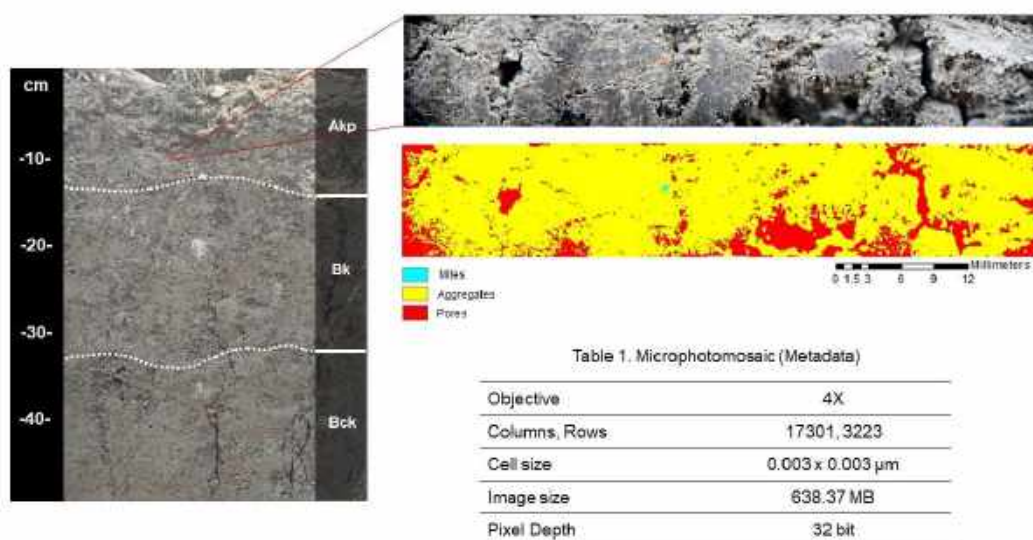

V V ENCINIA URIBE <sup>1</sup>, E V GUTIÉRREZ CASTORENA <sup>1</sup>, M D C GUTIÉRREZ CASTORENA <sup>2</sup>, V E AGUIRRE ARZOLA <sup>1</sup>, R E VÁZQUEZ ALVARADO <sup>1</sup>, J M MÁRQUEZ REYES <sup>1</sup>, T GONZÁLEZ VARGAS <sup>2</sup>

<sup>1</sup> Facultad de Agronomía, Universidad Autónoma de Nuevo León, General Escobedo, MÉXICO

<sup>2</sup> Programa de Edafología, Colegio de Postgraduados, Texcoco de Mora, MÉXICO

Over a century, different methodologies have been formulated to study soil genesis, morphology, and micromorphology. Despite the efforts achieved by researchers, the absence of In situ, non-destructive, and multiscale techniques is addressed in limited research, considering the implementation of study strategies at the threshold of the macrometric and micrometric scale (Baveye et al. 2018). For this purpose, a methodological proposal is proposed that includes studies of pedons (macroscale) with direct interaction with the digital micromorphometry (Hartemink & Minasny, 2014; Gutiérrez et al. 2018) of the soil In situ. The tests were carried out in a pedological profile of the Ap horizon, located in a moringa (moringa oleifera) production system. Images were captured in situ with a DSLR digital camera adapted to observation amplitudes of 4×, 10×, 40× and 100×; however, so far, it has only been possible to process real visible fields of 5 sequential images at 4× objective, thus creating an In situ microphotomosaic with an area of 111.65 mm<sup>2</sup>. A thematic map of micro and macroporosity was generated, identifying medium vesicular macropores, medium and fine irregular mesopores, and coarse and medium irregular micropores, covering an area of 35% of the total mosaic; others such as aggregates in subangular blocks of medium and coarse size, moderately developed, and partially accommodated, in an area of 64.7%; or mesofauna (mites), with only 0.3% of the total classified area. The description of the In situ micromosaic uses morphological and micromorphological scale terminologies quantified with micromorphometric image analysis techniques. Creating the In situ microphotomosaic establishes the first interactive advances between both scales of observation to study soils.

### MORPHO-FUNCTIONAL CLASSIFICATION OF HUMUS FORMS USING THE TERRHUM-APP: CORRELATION OF MORPHOLOGICAL INDICATORS AND STANDARDIZED LABORATORY ANALYSIS PARAMETERS

A. SCHRÖTTER<sup>1</sup>, K. KATZENSTEINER<sup>2</sup>, M. ENGLISCH<sup>1</sup>, M. MAYER<sup>2</sup>, C. GOLLOB<sup>2</sup>

<sup>1</sup> Austrian Research Centre for Forests, Vienna, AUSTRIA

<sup>2</sup> University of Natural Resources and Life Sciences, Vienna, AUSTRIA

The humus form classification system TerrHum assigns morphological features to ecological soil functioning. We tested if soil organic matter (SOM) turnover diagnosed by this ecological indicator tool corresponds to standardized laboratory analysis parameters. By sampling 30 survey plots of a forest site classification project in Styria, Austria, we cover calcareous and felsic parent material, a steep elevation gradient and different vegetation communities. Humus profiles were classified and sampled (horizon-wise) in a nested design. Organic carbon (OC) and nitrogen (N) concentration, pH value, microbial biomass carbon (MBC) and nitrogen (MBN), basal respiration (R10), temperature response (Q10) and eco-physiological quotients differ significantly between diagnostic horizons. There was evidence for SOM turnover patterns following the ranking supposed in the classification system. Rapid SOM turnover in Mull systems is confirmed by large microbial biomass (MBC), no constraints regarding organic matter quality (C/N ratio and microbial quotient), and high respiration levels (R10, and predicted Rh). Mor systems with retarded decomposition show low MBC, high acidity, and low litter quality. In Amphi and Moder SOM turnover is constrained. Moder horizons show higher acidity, slightly lower litter quality, lower respiration, and higher fungal abundance than corresponding Amphi horizons. In Amphi, and even more pronounced in Tangel systems (very slow SOM turnover), climatic factors are the main constraints for turnover. Heterotrophic respiration (Rh) for individual humus systems can be predicted with multiple regression models with moisture, temperature and diagnosed horizon as independent predictors. A multinomial logistic regression model confirmed that environmental factors have a significant influence on the distribution of humus systems along catenas. We conclude that the morpho-functional classification is a useful tool in characterizing the main SOM turnover types.

### ASSESSMENT OF TOPSOIL EVOLUTION ASSOCIATED WITH LAND USE CHANGE IN VAL CAMONICA SUBALPINE GRASSLANDS

S.L. CHERSICH<sup>1</sup>, A. ZANELLA<sup>2</sup>, M. D'AMICO<sup>3</sup>, L. GIUPPONI<sup>3,4</sup>, M. BOMBARDIERI<sup>4</sup>, F. FAVA<sup>1</sup>

<sup>3</sup> Department of Agricultural and Environmental Sciences Production, Landscape, Agroenergy, University of Milan, MILANO, ITALY

<sup>4</sup> Centre of Applied Studies for the Sustainable Management and Protection of Mountain Areas CRC Ge.S.Di.Mont., Edolo (BS), ITALY

Alpine pastures and meadows are agroecosystems with biological and landscape importance, protected by the European Union. Grassland areas had a rapid decline in the last decades due to changes in management and/or abandonment of traditional mountain farming in the Alps.

The aim of our study is the characterization of the relationship between historical and present-day subalpine grassland management, their plant diversity, soil properties and humus forms. Humus forms are important indicators of biological functioning of soils and of organic matter degradation pathways, easily affected by land use change.

We chose an area in Alta Valle Camonica (Rhaetian Alps, Lombardy), between 1800-2000 m a.s.l., on sialic glacial till, characterized by strong land use changes, as visible in historical aerial photographs. Since the 70s, large herbaceous surfaces are being colonized by subalpine heath and forests, because of a decreased and more localized grazing pressure. We selected 21 sites across six dynamic phases from grazed grassland to forest, in which we performed phytosociological surveys (10x10 m) according to the Braun-Blanquet method, a soil profile and a characterization of topsoil and organic horizons to detect humus types and properties. Standard physico/chemical soil properties were analyzed in the lab.

The widespread decrease in grazing intensity led to an expansion of less palatable grasses (e.g., *Nardus stricta* L.), shrubs and trees, and changes in plant diversity and vegetation structure. Soils are mostly Entic/Umbric Podzols, Histosols in bogs. Humus forms are more varied: we observed Para humus forms of Rhizo humus systems where grass roots were a main source of organic matter in soils. Mull and Amphi are the main forms in grazed areas, Dysmoders and Hemimoders in abandoned soils colonized by trees; no Mors have been detected.

Thus, humus forms and biological activity/organic matter degradation pathways can describe the gradients in land use change. Some more differences might be observed in the next experimental phases, with microbial analysis and topsoil thin section observations.

### WEED MONITORING AS KEY SOIL BIO-INDICATORS IN MANGROVE RICE PRODUCTION AGRO-ECOLOGIES IN GUINEA-BISSAU.

M. MERKOHASANAJ <sup>1</sup>, E. RIVERA <sup>1</sup>, A. ANDRETTA <sup>2</sup>, A. DELGADO <sup>3</sup>

<sup>1</sup> Centro de Estudos Florestais (CEF), Instituto Superior de Agronomia (ISA), Lisboa, PORTUGAL

<sup>2</sup> Dipartimento di Scienze Chimiche e Geologiche, Università degli Studi di Cagliari, Cagliari, ITALY

<sup>3</sup> Laboratorio de Biogeoquímica de Isótopos Estables, Instituto Andaluz de Ciencias de la Tierra IACT, GRANADA, SPAIN

Mangrove rice production (MRP) is crucial for guaranteeing food supply and environmental sustainability in Guinea-Bissau. Within this production system, different agro geological conditions exist, primarily attributed to variations in precipitation and temperature across the country, thus contributing to specific soil and water availability conditions.

Farmers local knowledge is key in recognizing and building co-innovative processes that will enhance soil fertility, rice production, thus, local communities well- being.

Utilizing on-site identification and leveraging the farmers' expertise for various plant species and their cultivation practices, recognizing their role in soil nutrient enrichment, the primary objective aimed at identifying predominant plant species, mapping their spatial distribution, and comprehending their distinct characteristics and nutritional impact. This initiative seeks to enhance agricultural productivity by boosting soil fertility while concurrently promote agro-ecological conservation within these communities.

This research was concentrated in two main coastal regions of the country, where we applied:

- Agro-ecologies general characterization
- Weed spatial distribution and image processing
- Transects for main weed identification
- Soil and isotopic analyses

Results from image classification show a high capability to distinguish green biomass into main classes such as: weed predominant species, water, soil, and others (secondary species with very low abundance).

Agro-ecological characterization showed TM (Tidal Mangrove) to have a better fertility status even with few present salinization limitations. In contrast, the AM (Associated Mangrove), despite their weaker fertility status, have higher organic carbon and nitrogen content.

There is a clear top-down weeds distribution, indicating three predominant weed species as Blutaparon Vermiculare, Sesovium portulacastrum (TM) and Enchinochloa (AM).

Weeds exhibit a wide dispersion of  $\delta^{15}\text{N}$  values ranging from  $-1.5\text{‰}$  to  $+9.5\text{‰}$  (AIR). These values are consistent with various nitrogen sources and, notably, with the nitrogen dynamics in the soil. The  $\delta^{13}\text{C}$  values of organic matter in soils indicate the percentage contribution of C3 and C4 biomass. Spatial patterns and specific in-situ conditions have been identified as influential factors on the isotopic signals of  $\delta^{15}\text{N}$  and  $\delta^{13}\text{C}$  in weeds.

Figure 2: Isotopic  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  for 49 soil samples and 2024 vegetation species taken during field campaign 2022.

Figure 3: Isotopic  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  for three principal identified species (1024) from field campaign July 2022.

## HUMIPEDON DYNAMICS IN ALPINE SOILS AFTER A SEVERE WINDSTORM

F. VISENTIN <sup>1</sup>, A. ZANELLA <sup>2</sup>, S. REMELLI <sup>1</sup>, C. MENTA <sup>1</sup>

<sup>1</sup> University of Parma - Dept. of Chemistry, Life Sciences and Environmental Sustainability, Parma, ITALY

<sup>2</sup> University of Padova - Dept. of Land, Environment, Agriculture and Forestry, Padova, ITALY

In October 2018, “Vaia” storm hit the Italian Alps, causing major damage to forests. The resulting changes in microclimate and soil structure are expected to shape the structure of soil communities and the dynamics of humus formation and of soil organic matter (SOM) accumulation.

In Val Di Fassa (Trentino-Alto Adige, Italy), 12 sites were identified, uniform in altitude and plant composition, half of which was hit by the storm. Soil samples of 3 conditions were taken: intact forest (IF); under grass in windthrow areas (G); under decaying wood in windthrow areas (W). For each sample, Humus system was identified, soil arthropod community were analysed, and SOM stored in organic (O) and organo-mineral (A) soil horizon was quantified.

Regarding Humus, the majority of IF samples express Amphi system (86%). This percentage drops to 50% in windthrow areas, with small differences between G and W, where the other 50% is represented majorly by Mull system. SOM quantification shows a similar pattern, with IF containing a greater quantity of SOM compared with G and W. Considering also soil microarthropods communities' parameters (abundances, number of taxa, Shannon index, QBS-ar index), FAMD Analysis shows that the IF category is the only cluster that deviates from the others and that there's no clear differentiation between G and W. Only the structure of the community in W was different from the other categories.

In conclusion, in studied forest sites, the passage of Vaia storm produced a shift in the functionality of the humipedon, from a system characterized by a medium speed of SOM turnover (Amphi) to one with a faster turnover of SOM (Mull). The differences are clear between intact forest soils and windthrow soils, but not between conditions in windthrow soils. The small differences observed between G and W suggest that different management of windthrow areas cannot influence humipedon dynamics in these few years after the disturbance. Longer monitoring is needed to help address this question

**Keywords:** Alpine Humus, Soil microarthropods, Windthrow, SOM dynamics

### 7.09 133552 - Nature based solution for sustainable soil and water management

#### THE NBSOIL PROJECT - NATURE BASED SOLUTIONS FOR SOIL MANAGEMENT

E PADOAN, A GIORDANO, E BORGOGNO MONDINO, M SCHIAVON

Università degli Studi di Torino - Dipartimento di Scienze Agrarie, Forestali e Alimentari, Torino, ITALY

NBSOIL (Nature Based Solutions for Soil Management) is a four-year project coordinated by the Institute of Soil Science and Plant Cultivation (PL). Its overall objective is to design an attractive blended learning programme to enable soil advisors to implement a holistic vision of soil health through Nature Based Solutions (NBS) and collaborate effectively across different temporal and spatial scales.

NBSOIL will focus on 6 multifunctional NBS categories to develop a holistic approach to land management and soil health fully in line with the IUCN Global Standard for NBS (IUCN, 2020): organic fertilisers from locally available biowastes, cover crops, paludiculture, forest diversification, bioremediation, and blue - green infrastructure in urban and periurban areas. NBSOIL builds on previous research results and available Open Source technology to deliver the following NBSOIL thematic packs: Knowledge base, Academy, Soil Health assessment, monitoring and mapping resources, Policy Navigator, and Marketplace.

Approximately 300 participants from 8 countries (PL, AT, CH, UK, FR, NL, IT, ES) are expected to complete the full 2 years training offered in 6 languages (English, Polish, German, Dutch, French, Italian, Spanish). The 2 years training programme will provide an immersive, interactive, flexible learning experience, through an introductory MOOC and four advanced modules on 1. Soil and NBS, 2. Living Labs facilitation, 3. Digital tools for Soil Health monitoring and 4. Improving soil related decision making in business and policy, and a Final Project.

The NBSOIL consortium will deliver Impact and contribute decisively to achieve the Soil Health Mission by mainstreaming NBS knowledge and advice for soil management, providing Soil Health Living Labs facilitators, making soil monitoring and mapping tech user friendly and inclusive and embedding soil care across all land management and land related decision making processes.

#### THE IMPACT OF CONVENTIONAL AND PRECISION CULTIVATION TECHNOLOGY ON THE MOISTURE CONTENT OF THE CHERNOZEM SOIL

T RÁTONYI, P FEJÉR, É HORVÁTH, A SZÉLES, P RAGÁN, C BOJTOR, Á ILLÉS, E HARSÁNYI

University of Debrecen, Institute of Land Use, Engineering and Precision Farming Technology, Debrecen, HUNGARY

Efficient water management is crucial for optimising crop yields and developing sustainable cropping systems. The measurement of moisture content in the soil of the long-term field experiment provides insights into the interaction between cultivation methods and water conservation.

The studies were carried out in a long-term field experiment at the Látókép Crop Production Experimental Station of the Institutes for Agricultural Research and Educational Farm of the University of Debrecen, Hungary (N 47° 33' E 21°26'). Soil moisture measurements were conducted in the soil of the long-term field experiment set up on calcareous soil. The probe measures soil moisture content using an FDR sensor and records it as percentage of field capacity (FWC). The measured values were converted to volumetric water content (VWC). Measurements were taken every two weeks during the growing season of maize. The measurements were used to monitor the movement and distribution of soil moisture within the 0-80 cm soil profile.

The treatments included in the experiment significantly affected soil moisture. Under non-irrigated conditions, a significant difference was observed between conventional and strip tillage treatments at all measurement times. Soil moisture content measured in the ripping treatment did not differ significantly from the conventional winter ploughed and strip tillage treatments. There was an average difference of 3-4 vol% moisture between the tillage treatments at the top 80 cm soil depth, which was stabilised at nearly the same level at all measurement times during the growing season. The additional water applied by means of irrigation eliminated the differences in moisture content between the tillage treatments. Significant soil moisture differences were measured between the control and fertilised treatments. In most of the performed measurements, there was no significant difference in soil moisture between the 80 kg N/ha and 160 kg N/ha treatments. Significantly higher soil moisture was measured in the control plots in both irrigated and non-irrigated treatments, and 5-7 vol% lower in the 160 kg N/ha treatment.

#### NATURE BASED SOLUTIONS FRAMEWORK FOR AGRO-ECOLOGICAL TRANSITION IN SERBIA

S SEREMESIC<sup>1</sup>, J GRABIC<sup>1</sup>, J NINKOV<sup>2</sup>, F ALTOBELLI<sup>3</sup>, M MILASINOVIC SEREMESIC<sup>4</sup>, B VOJNOV<sup>1</sup>

<sup>1</sup> University of Novi Sad, Faculty of Agriculture, Novi Sad, SERBIA

<sup>2</sup> Institut za ratarstvo i povrtarstvo, Novi Sad, SERBIA

<sup>3</sup> CREA - Council for Agricultural Research and Economics, Roma, ITALY

<sup>4</sup> Institute of food technology, Novi Sad, SERBIA

Nature-based solutions (NbS) approach in agriculture aims at establishing some new agri-food systems relationships to bring health co-benefits and achieve global food security similar to agroecology. These similarities are most pronounced in methods (conservation agriculture, agroforestry, nutrient management, C-farming reforestation etc.) that can be used to reach the goals of sustainability in food production and addressing societal challenges. The differences between these two concepts are how they access the problem - while NbS has a top-down approach, agroecology uses using bottom-up direction. The territory is argued to be a decisive point for both NbS and agroecology as a place where these two concepts overlap. Conversely, this could be an advantage for reaching the inclusiveness and synergies necessary for scaling out sustainable systems that lead to multiple benefits in agriculture. This could help the current system of agricultural production encompassing the farm vs. food system approach and foster the integration of methods and mechanisms of transition to establish the new food systems. Identifying where the territorial domain of NbS and agroecology overlap is important and may represent the eatery point where the transition of agriculture can be initiated. Given the agroecological background and socio-economical conditions, we can propose using such an approach to agri-food transformation in Serbia. Developing a coherent policy framework based on a holistic performance covering sustainable intensification and traditional food production based on innovation could be a way forward in agri-food improvement.

#### ECONOMIC VIABILITY OF CARBON FARMING THROUGH COMBINED INCENTIVE MECHANISMS.

A MARTELLI, I CRISCUOLI, F GALIOTO, G DARA GUCCIONE, G BONATI

CREA Research Centre for Agricultural Policies and Bioeconomy, Rome, ITALY

The study evaluates the economic viability of carbon sequestration practices in agricultural soils (carbon farming, CF). It is based on a simulation analysis built upon available literature referring to temperate regions and considers existing and potential incentive schemes. Currently, The European Common Agricultural Policy (CAP) offers incentives to encourage CF and voluntary carbon markets (VCMs) are expected to be formalised through the European regulation on carbon removals. CF practices analysed in this study refer to soil management, crop management, crop rotation, and land use change. Each practice represents a different cost to land managers; incentives might provide an opportunity to cover such costs. An overview of the carbon sequestration potentials and costs of these practices enabled the estimation of a marginal abatement cost curve, considering a baseline scenario of conventional monoculture on arable land with maize (irrigated) and wheat (non-irrigated).

This information was then used to feed an economic interpretative model that allows identifying which financial mechanism is more appropriate in promoting CF practices, and the minimum size for CF projects, that is the operational scale below which a CF project may not be economically viable. The minimum size is essential to balance economic, environmental and practical aspects in CF projects, ensuring their long-term effectiveness and sustainability. The analysis reveals that the minimum size is significantly lower for land use change strategies than for other practices and much lower under CAP payments than under VCMs. However, CAP and VCMs currently only partially offset the costs of climate mitigation actions, making further financing mechanisms necessary. In conclusion, the analysis draws recommendations for both VCM and CAP, highlighting the need for comprehensive strategies to improve the effectiveness of incentives in addressing climate challenges. It is suggested that existing Information, Administration and Control Systems (IACS) are used both for the management of CAP payments and the issuing of carbon credits, to reduce transaction costs, preventing the risk of double financing and facilitating monitoring.

**SUSTAINABLE FORESTRY: THE IMPERATIVE OF SOIL MAPPING IN FOREST RESOURCE INVENTORY, MODELLING AND MANAGEMENT IN SCOTLAND, UK**

R HEWISON <sup>1</sup>, A J NOLAN <sup>2</sup>, D J RIACH <sup>1</sup>, S ADDY <sup>1</sup>, D DONNELLEY <sup>1</sup>, L BEESLEY <sup>2</sup>, D J HENDERSON <sup>2</sup>, J S BELL <sup>2</sup>, V BROSNAN <sup>3</sup>, J HAUFE <sup>3</sup>

<sup>1</sup> James Hutton Institute, Aberden, UNITED KINGDOM

<sup>2</sup> Former Employee of James Hutton Institute, Aberdeen, UNITED KINGDOM

<sup>3</sup> Forest Research, Edinburgh, UNITED KINGDOM

Site specific knowledge of soil resources is essential to understanding their potential contribution to silvicultural management.

This is particularly important in Scotland, UK, where there is great diversity of climate, geology, landscapes and soils within a relatively small area.

An approach based on soil classification and mapping has been devised to incorporate detailed soils information into decision support for silvicultural management.

Detailed soil surveys are a vital component in the decision-making process whether to grow trees and if so, what species and how best to manage stands.

Scotland's landscape has been radically changed by human influence, with forest cover reduced to 4% by the early 1900s.

Re-establishing woodland cover was identified as a national priority and during the 20th Century, extensive planting took place to create a largely state-owned forest estate.

Forest cover is now approximately 18% with a vision of around 25% for mid-late 21st Century.

Expansion of native woodland is also underway to meet nature conservation and Habitat Action Plan targets.

Detailed soil mapping is now deemed as an essential aspect of forest inventory planning.

The James Hutton Institute has worked on this project for the last 14 years, mapping around 850 km<sup>2</sup> at a detailed scale of 1:10,000.

#### CONTRIBUTION OF COMPONENTS IN NATURAL SOIL TO CD AND PB COMPETITIVE ADSORPTION: SEMI-QUANTITATIVE TO QUANTITATIVE ANALYSIS

Y. LI <sup>1</sup>, G. GARLAND <sup>2</sup>, X. LIU <sup>1</sup>

<sup>1</sup> Zhejiang University-College of Environmental and Resource Sciences, Hangzhou, CHINA

<sup>2</sup> ETH Zurich-Department of Environmental Systems Science, Zurich, SWITZERLAND

Cadmium (Cd) and lead (Pb) are two of the most common elements found in contaminated terrestrial sites. Multiple heavy metals can compete for the same sorption sites in the soil, affecting and increasing the availability and types of heavy metals released to the environment. In this study, adsorption experiments, multi-surface models, and advanced spectroscopy technology were employed to explain the adsorption mechanism of Cd and Pb and to quantify the contribution of soil components in this system. The results show that pH is the main factor determining the contribution of soil components to metal adsorption while soil organic matter (SOM) is the dominant adsorbent for both Cd and Pb. Clay minerals play an adsorption role at low pH, whereas Fe/Al oxides adsorb metals primarily in the high pH range. Furthermore, the competitive effect of Pb on Cd was largely observed on SOM rather than on clay minerals. When the Pb concentration increased from 0 to 500 mg/L, the adsorption of Cd on SOM decreased by 132 mg/kg, whereas it decreased only by 1.9 mg/kg on clay minerals. Thus, the competitive effect of Pb on Cd is especially prominent in soils with high organic matter content. Pb may lead to the occupation of adsorption sites on SOM, thereby enhancing the mobility of Cd. Therefore, prediction based on a single metal may underestimate the risk of Cd in the environment.

#### EFFECT OF MICROENCAPSULATION ON THE PERSISTENCE AND LEACHING OF DELTAMETHRIN IN AGRICULTURAL SOILS

H. MORENO-RAMÓN, J. HERNÁNDEZ-SANTOLARIA, S. IBÁÑEZ-ASENSIO  
Universitat Politècnica de València, Valencia, SPAIN

The European Commission established halving the use of chemical pesticides by 2030. This aims to reduce greenhouse gas emissions and reverse soil degradation, improving its quality. This fact has caused companies producing phytosanitary products to begin to develop more sustainable products or improve the effectiveness in the application of active substances. However, there are pests that for the moment must be controlled with the application of active substances. This is the case of cottonet (*Delottococcus aberiae*) in the citrus and persimmon production sector in the Valencian Community (Spain), which is causing million-dollar losses. Therefore, in NECOTDIM project an experience to analyse the effect of microencapsulation of Deltamethrin in soils and leachates has been carried out. In some plots, the microencapsulated product was applied in different doses and the effect of deltamethrin degradation was observed, as well as its concentration in installed lysimeters. The main outcomes revealed that microencapsulation allowed deltamethrin to remain at higher concentrations in the plot, since the active substance is slowly released and therefore the effect on pest is higher in time. The main results revealed that microencapsulation favored higher concentrations in the soil as the active ingredient was slowly released, being better in the fight against the pest. 5.92 mg/g of Deltamethrin concentration was the difference between the microencapsulated and the non-encapsulated, registering a deltamethrin reduction rate between 82-88% in 100 days. Deltamethrin was positively correlated with Organic carbon and total nitrogen, and negatively with soil pH. Microencapsulation also presented effects on leachates, since for flood irrigation, the application of non-microencapsulated deltamethrin presented higher values (0.026 mg/L) than the microencapsulated one (0.014 mg/L), being in the case of irrigation by similar drip (0.0064 and 0.0066 mg/l, respectively). Therefore, it can be concluded that microencapsulation favors the retention of the active substance in the soil, with the concentration of deltamethrin being higher in the leachates of those applications without microencapsulation in the case of flood irrigation.

### MINERAL NANOPARTICLES SYNTHESISED FROM COAL MINING WASTE FOR AGRICULTURAL PURPOSES

E. BORTOLUZZI<sup>1</sup>, T. BENEDETTI<sup>1</sup>

<sup>1</sup> University of Passo Fundo, Passo Fundo, BRAZIL

<sup>2</sup> University of Passo Fundo, Passo Fundo, BRAZIL

This study reports the synthesis of iron-based oxide nanoparticles (IONP) using acid mine drainage (AMD) water and their bioavailability to plants as an agricultural fertilizer and as a biocontrol agent. The size of the synthesized particles was below 100 nm for 95.9% of them, which predominantly presented hematite and positive charges on their surface. Sulfur, magnesium, silica, potassium, and phosphorus were among the nutrients found in IONPs composition. The synthesized particles were also able to release and trapped by cation and anion resin membranes significant amounts of available iron, calcium, magnesium, and phosphorus ions into water, which allows the IONP to be characterized as a nano-fertilizer for agriculture. In addition, IONP, due to its specific properties, represents a tool to mitigate the limitations of biological agents and has also shown potential in the management of plant diseases. The application of IONP (at the dose of 75 mg kg<sup>-1</sup>) in association with a biological agent reduced *M. javanica* females in the roots of soybean.

This study allows us to infer that the nano iron may be made by a friendly strategy using mining waste. In addition, this systemized IONP has the potential to be used in agriculture as a source of some nutrients and as an efficient agent in the management of plant-parasitic nematodes.

<sup>2</sup> University of Seville - Department of Plant Biology and Ecology, Seville, SPAIN

<sup>3</sup> University of Almería - Department of Agronomy, Almería, SPAIN

<sup>4</sup> University of Seville - Department of Microbiology and Parasitology, Seville, SPAIN

Agricultural soil degradation primarily stems from the combined effects of climate change and the intensification of agricultural practices. Inoculating plant growth-promoting microorganisms (PGPM) emerged as a promising solution to enhance agricultural practices sustainably, offering simultaneously an alternative to chemical fertilizers, pesticides, and supplements. In recent years, scientists have extensively studied PGP properties, especially in bacteria and, to a lesser extent, in cyanobacteria. However, the most recent research has mainly focused on finding these beneficial microorganisms in agricultural soils, especially in the root zones of crop plants, while other niches such as biocrusts are unexplored. The main goals of this work were (i) to isolate heterotrophic bacteria strains in biocrusts collected from semi-arid study sites and (ii) to characterize the functional traits associated with plant growth promotion and enzymatic activities of both newly isolated heterotrophic bacteria and previously identified biocrust-forming cyanobacteria. The cyanobacteria strains used in this study were isolated from biocrusts of semi-arid ecosystems from Spain and Italy where they are ubiquitous and belong to the species *Nostoc commune*, *Tolypothrix distorta*, *Trichocoleus desertorum*, *Stenomitus frigidus*, and *Scytonema hyalinum*. Moreover, twenty-six heterotrophic bacterial strains were isolated from one of these ecosystems. Quantitative and qualitative tests were conducted to assess their PGP properties, including the production of indole-3-acetic acid (IAA), siderophores, phosphate solubilization, nitrogen fixation, biofilm formation, and the presence of enzymatic activities such as ACC deaminase, DNase, amylase, catalase, oxidase, lipase, and protease. The test results reveal that among the cyanobacteria, the strain *N. commune* CANT2 exhibited the highest number of PGP properties, followed by *N. commune* NR64 and *N. commune* AB55. Bacterial strains with a greater number of PGP traits were identified by sequencing the 16S rRNA gene. The strain *Peribacillus frigoritolerans* AMO has emerged as the most promising candidate for future application as a biofertilizer. Developing microbial inoculants from these strains has the potential to innovate plant cultivation, fostering increased environmental sustainability and reduced reliance on chemical inputs.

#### CO-APPLICATION OF ZINC AND PHOSPHORUS FERTILISERS TO AGRICULTURAL SOILS: EFFICACIOUS FOR PLANT NUTRITION, OR AN INEFFECTIVE MICRONUTRIENT PRACTICE?

E. SMITH<sup>1</sup>, C. DOOLETTE<sup>1</sup>, P. KOPITKE<sup>2</sup>, E. LOMBI<sup>1</sup>

<sup>1</sup> Future Industries Institute, University of South Australia, Adelaide, AUSTRALIA

<sup>2</sup> School of Agriculture and Food Sustainability, University of Queensland, Brisbane, AUSTRALIA

#### Introduction

Macronutrient fertilisers coated with Zn offer economic and agronomic benefits for crop production. Ammonium phosphates are the most commonly used P-fertilisers coated with Zn. However, the dissolution and subsequent bioavailability of Zn in these fertilisers is complex. In fertiliser granules, Zn concentrations typically range from 10,000 to 50,000 mg Zn/kg (1-5% Zn w/w) compared to 10-300 mg Zn/kg<sup>1</sup> in soils. The behaviour of Zn dissolution in the sphere of soil surrounding the fertiliser granule (the fertosphere) is unlikely to follow Zn behaviour observed in the bulk soil. The objective of this study was to investigate the behaviour of Zn coated P fertilisers in the fertosphere of acidic and alkaline soils.

#### Materials & Method

Two soils with contrasting physiochemical parameters were placed in a petri dish and incubated for 7 days at 80% WHC after which one Zn coated fertiliser granule was placed in the middle of the petri dish at a depth of 5-mm. The Zn coated fertiliser granule was left in place for 28 days after which the soil adjacent to the granule was collected. The fertiliser treatments were Zn-coated urea, Zn-MAP, Zn-DAP, and co-granulated Zn-DAP. Dried soils of various distances were analysed for pH, EC, total Zn and P concentration, Zn availability (DGT and E-value) and distribution and speciation (XFM and XAS).

#### Results

Analysis of the collected soils found higher Zn concentrations in the soil collected adjacent to the fertiliser granule. The total Zn concentration was dependent on both the fertiliser and the soil type (Figure 1). Zn coated urea contained the highest total Zn concentration compared to all the other treatments. In the Zn coated urea treatment, no intact fertiliser granule was recovered but fertiliser granules were recovered from all other treatments indicating fertosphere chemical limited Zn dissolution in this study.

Figure 1. Zn distribution and total concentration in soils (0-8-mm blue, 8-15 mm orange, 15-25-mm grey, >25-mm yellow).

#### RICE GROWTH AND YIELD, AND SOIL NUTRIENTS IN NATURE FARMING PADDY FIELDS WITHOUT FERTILIZATION AND PESTICIDES IN MOUNTAINOUS AREA IN SOUTHWEST JAPAN

H. UENO <sup>1</sup>, S. NISHIMURA <sup>2</sup>, K. MORI <sup>2</sup>, Y. OKAMURA <sup>2</sup>, E. SAKAMOTO <sup>2</sup>, K. KIKUCHI <sup>3</sup>

<sup>3</sup> Kumakko Farm, Toon, Ehime, JAPAN

The main raw materials for chemical fertilizers are fossil fuels and mineral resources. These resources have a limited shelf life, making sustainable food production impossible under the current cultivation system. Therefore, it is necessary to develop cultivation methods that reduce fertilizer use. In this study, we focused on long-term rice paddies cultivated without fertilizers or pesticides and investigated the growth and yield of rice paddies and their soil nutrient supply characteristics. In 2023, we tested nature farming (NF) paddy fields in which rice has been cultivated without fertilizer or pesticides for more than 10 years in the mountainous area of Ehime Prefecture, Japan. Conventional farming (CF) rice paddies in the neighborhood were used as control plots. The yield of brown rice in NF was 2920 kg ha<sup>-1</sup>, which was 32% lower than that in CF. However, the number of rice grains per ear was significantly higher in NF, suggesting that sufficient nutrients were supplied during juvenile ear formation. Regarding the appearance quality of brown rice, the grain quality ratio was significantly ( $P = 0.05$ ) higher in NF than in CF, and the number of immature grains was lower in NF. The small sink size per unit area in NF is considered to have resulted in sufficient accumulation of carbonate assimilation products. Furthermore, the protein content in nature farming was lower than that in CF, and the eating quality was significantly higher in NF. The ammonia nitrogen content in the soil of NF remained higher than that of CF throughout the growing period, indicating that the soil fertility of NF was relatively high despite no fertilization (Fig. 1). The amount of nitrogen absorbed by rice per hectare in NF was 50% of that in CF, but the grain yield was 70% of that in CF, suggesting that increasing nutrient absorption efficiency by suppressing weeds is a factor in increasing yield in NF (Fig. 2).

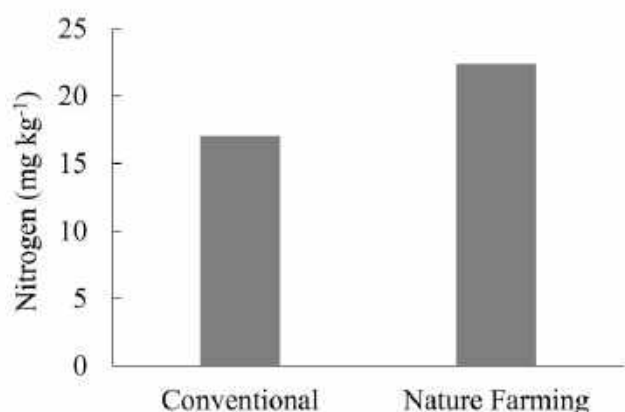

Fig. 1. Average concentrations of ammonia-N in the soils under conventional and Nature Farming.

Fig. 2. N uptake by rice and weeds in conventional and Nature Farming.

#### THE IMPACT OF CONVENTIONAL AND PRECISION FARMING TECHNOLOGY ON MAIZE YIELDS

E HARSÁNYI <sup>1</sup>, P FEJÉR <sup>2</sup>, A TAMÁS <sup>2</sup>, A SZÉLES <sup>2</sup>, P RAGÁN <sup>2</sup>, C BOJTOR <sup>2</sup>, Á ILLÉS <sup>2</sup>, T RÁTONYI <sup>2</sup>

<sup>1</sup> University of Debrecen, Technology Institutes for Agricultural Research and Educational Farm, Debrecen, HUNGARY

<sup>2</sup> University of Debrecen, Institute of Land Use, Engineering and Precision Farming Technology, Debrecen, HUNGARY

Strip tillage is a conservation tillage practice employed in maize production, involving the cultivation of narrow strips where seeds are planted while leaving the intervening space undisturbed. The undisturbed residue cover in between the tilled strips acts as a protective layer, preventing soil erosion and promoting overall soil health, making strip tillage an advantageous approach in sustainable maize farming.

The studies were carried out in a long-term field experiment (crop rotation x tillage x fertilization x irrigation x plant density x genotype) at the Látókép Crop Production Experimental Station of the Institutes for Agricultural Research and Educational Farm of the University of Debrecen (N 47° 33' E 21°26') on calcareous chernozem soil. The tillage in the experiment were winter ploughing, precision strip tillage and primary tillage with a ripper. The fertilizer levels were control, 80 kg N/ha + 60 kg P<sub>2</sub>O<sub>5</sub> /ha + 90 kg K<sub>2</sub>O/ha; and 160 kg N/ha + 60 kg P<sub>2</sub>O<sub>5</sub> /ha + 90 kg K<sub>2</sub>O/ha.

The yields of the 9 years of the trial (2015-2023) were evaluated with repeated measures ANOVA with Least Significant Difference test.

In the scope of the study, the highest yields were recorded in the case of ripped tillage with 160 kg N/ha +PK fertilizer treatment (14.46 t/ha in 2016), and this was not significantly different from winter ploughing with the identical fertilizer treatment in the same year.

The lowest maize yield (1.66 t/ha) was in the severe drought year of 2022, in the case of the winter ploughing 160 kg N/ha + PK treatment. The highest maize yield in strip tillage treatment was in 2016 in the 160 kg N/ha +PK fertilizer treatment which was only 1.2 t/ha less than the highest yield of the period. In the final year (2023), strip tillage provided significantly lower yields than winter ploughing. However, this difference was only 0.56 t/ha, which is compensated with the reduced amount of fuel consumption.

**Keywords:** long-term experiment,conventional tillage,precision strip tillages,fertilization,maize yield

Implementation of Horizon 2020 project "Promoting SMART agricultural WATER management in Bosnia and Herzegovina" (SMARTWATER) started on 1.1.2021. The Coordinator of SMARTWATER is the University of Banja Luka Faculty of Agriculture (UNI-BL). Project consortium consists of partners from BiH, Spain, Portugal and Italy. The main objective of SMARTWATER is to reinforce networking, research and S&T cooperation capacities of the University of Banja Luka (UNI-BL), the University of Sarajevo (UNSA) and other connected national institutions, in the field of sustainable agricultural water management and to increase their competency and fund-raising skills for a successful participation in the European Union Research Programs. The basic project scientific themes include: 1) cloud-based smart technologies, 2) new generation of satellite remote sensing data, 3) water-energy-food nexus and 4) climate change impact on agriculture. As part of WP3, a 3-year joint experimental studies on maize (*Zea mays* L.) at two locations in BiH and with different irrigation and fertilization regimes were also performed. With data from these experiments, several academic papers were already published open access in international Journals . Project teams promoted SMARTWATER at 20+ international conferences in BiH and abroad. In period 2021-2023 project consortium organized 3 advanced training courses, 3 summer schools, 3-year experiments, 2 stakeholders' meetings (roundtables), 3 MSc courses, 10 mutual staff exchanges, 3 R&I hands-on workshops and many more. Posts about our activities are published at social media profiles (Facebook, Twitter/X, LinkedIn) and the SMARTWATER website . SMARTWATER project officially ends in June 2024. Twinning activities in 2024 (academic exchanges, dissemination etc.) will be aimed at promoting smart management of agricultural resources, upgrade of networking and research between partner institutions and work with project stakeholders. We ask all interested actors to visit our sites, to attend our events and to join the SMARTWATER network.

### 8.03 133541 - Sustainable Soil Nutrient Management: Implications for Food, Environment, and Ecology

**ACQUISITION OR UTILIZATION, WHICH IS MORE CRITICAL FOR ENHANCING PHOSPHORUS EFFICIENCY BY MAIZE LANDRACES IN ACID SOILS OF MEXICO?**

J.S. BAYUELO JIMENEZ

Universidad Michoacana de San Nicolás de Hidalgo, MORELIA, MEXICO

Low phosphorus (P) availability is a principal constraint to crop production worldwide. In most soils, soil and fertilizer P are easily bound by either soil organic matter or chemicals, and thus are unavailable to plants. Therefore, the development of P-efficient crop varieties that can grow and yield better with low P supply is a key to improving crop production in the central Mexican highlands. This study evaluated the contribution of root architecture and plant growth traits associated with P acquisition efficiency (PAE) and/or P utilization efficiency (PUE) of maize landraces from the Purhepecha Plateau, Michoacan on a P-deficient Andisol with low and high P fertilization under rain-fed conditions. The results showed that both PAE and PUE were critical factors explaining the variation in P use efficiency at both P levels. Late maturing P efficient genotypes showed the greatest variation for P uptake per unit root weight and growth under low P. The  $^{32}\text{P}$  isotope dilution technique was employed to assess the ability of the genotypes tested to utilize P from different P sources. P-efficient genotypes accessed soil P not available to P-inefficient ones, whereas the P-responsive genotypes showed increased P acquisition from fertilizer. Greater P utilization efficiency was related to an improved distribution of dry matter in the plants and a lower absorbed P allocated in the grain. On a P-deficient acidic soil, early genotypes, were categorized as the most P efficient and the most responsive to increased P availability. These results indicate that maize landraces exhibit variation for several plant growth traits that may be useful for genetic improvement of P use efficiency in maize.

### 8.08 133822 - Peatlands in a changing world

#### NUTRIENTS AND DISSOLVED ORGANIC CARBON DYNAMICS IN RESPONSE TO ENVIRONMENTAL DRIVERS IN A BELGIAN PEATLAND

M. HENRION <sup>1</sup>, E. ANCIAUX <sup>1</sup>, A. MOORE <sup>1</sup>, S. LAMBOT <sup>1</sup>, K. VAN OOST <sup>1</sup>, F. JONARD <sup>2</sup>, S. OPFERGELT <sup>1</sup>, V. VANACKER <sup>1</sup>

<sup>1</sup> Earth and Life Institute, Université catholique de Louvain, Louvain-la-Neuve, BELGIUM

<sup>2</sup> Earth Observation and Ecosystem Modelling Laboratory, SPHERES Research unit, Université de Liège, Liège, BELGIUM

Peatlands are providing crucial ecological services such as significant carbon storage. These sensitive ecosystems are subjected to degradation due to land use and climate change resulting in carbon emissions. Multiple studies focused on the gaseous carbon fluxes from disturbed peatlands while dissolved carbon fluxes have often been overlooked. However, hydrologic export of carbon can represent up to 30 % of the ecosystem carbon exchanges and is highly variable.

We investigated the spatiotemporal variability in dissolved carbon in a peatland located in the Belgian High Fens. The site was previously drained for forestry and is now under passive restoration. These disturbed peatlands are understudied despite their ubiquitous presence in the Ardennes-Eifel region. It is therefore important to understand their actual state and their recovery potential. Our objectives are to: (i) characterize the spatiotemporal variability in dissolved nutrient and carbon concentrations in soil solutes; (ii) investigate the association between soil moisture, redox conditions and nutrient and carbon concentrations; (iii) identify hot-spots or hot-moments in the biogeochemical functioning of peatlands.

Soil pore water samplers were installed at five contrasting positions along a toposequence, at three different depths. Soil pore and river waters are collected and analyzed once per month during one year. These water samples are analyzed for their conductivity, pH, major element concentrations, dissolved C, dissolved N, NO<sub>3</sub>, NH<sub>4</sub>, Cl, organic carbon aromaticity and Fe(II)/Fe(III) ratio. At the same topographic positions, sensors were installed to record continuously soil temperature, moisture and electrical conductivity. This provides a finer temporal resolution to study the influence of soil moisture on the soil electrical conductivity, and thereby nutrients mobility.

Our first results revealed that meteorological events influenced concentrations of nutrients and organic carbon. They also demonstrated the importance of the ground water dynamics in controlling the soil conductivity and pH equilibriums. Finally, the soil solute chemistry varied largely as function of topographic position and sampling depth; and will be further analyzed in terms of hydrologic export.

#### ANALYSIS OF PEAT SOIL CHARACTERISTIC AND ENVIRONMENTAL PARAMETER VARIABILITY IN CONTROLLING CO<sub>2</sub> EMISSION ON THE TROPICAL PEATLANDS AGRICULTURE

F. SIMANJUNTAK <sup>1</sup>, N. .I. FAWZI <sup>2,3</sup>, SUWARDI <sup>2</sup>, B. SUMAWINATA <sup>2</sup>

<sup>1</sup> Astra Agro Lestari Tbk, JAKARTA, INDONESIA

<sup>2</sup> Soil Science and Land Resources Department, Faculty of Agriculture, IPB University, BOGOR, INDONESIA

<sup>3</sup> Tay Juhana Foundation, JAKARTA, INDONESIA

Peatland utilization for agriculture in Indonesia has a history dating back to the 1920s, initiated by the Banjar community in South Kalimantan, and has experienced significant growth over the years. Agricultural practices involving drainage in peatlands consistently draw attention as a significant contributor to atmospheric CO<sub>2</sub>, accelerating peat oxidation and releasing carbon stocks as CO<sub>2</sub> gases. This research focuses on peatlands utilized for coconut plantations and oil palm, implementing water management practices following responsible peatland management since 1986 and 1994. Research findings indicate that environmental parameters such as groundwater table, soil moisture, and soil temperature do not directly control the magnitude of CO<sub>2</sub> emissions. Changes in the physical characteristics of peat, such as the degree of decomposition, determine the availability of organic material that can be further oxidized and released as CO<sub>2</sub> emissions. Field measurements indicate that peat soil emissions are partly influenced by root respiration rather than by the loss of organic matter on peat. CO<sub>2</sub> emissions from peat soil (heterotrophic respiration, RH) are 7.77 t C-CO<sub>2</sub>/ha/year in coconut plantations and 11.1 t C-CO<sub>2</sub>/ha/year in oil palm plantations, while autotrophic emissions (RA) contribute 212% to 424% to soil respiration (RS) in peatlands. Bulk density was observed every 10 cm of the peat layer, revealing that 81% of subsidence in peat occurs due to compaction, with bulk density values changing from 0.072 gr/cm<sup>3</sup> to 0.146 gr/cm<sup>3</sup> and 0.144 gr/cm<sup>3</sup> in oil palm and coconut plantations. Therefore, estimating CO<sub>2</sub> emissions by converting subsidence data in peatlands may have limited applicability. A comprehensive understanding of processes in tropical peat, especially for agricultural cultivation, is crucial for evaluating CO<sub>2</sub> emission calculations in peatlands and climate change mitigation for sustainable peatland management.

#### RECOVERY OF FEN PEATLAND MOLECULAR COMPOSITIONS AFTER REWETTING

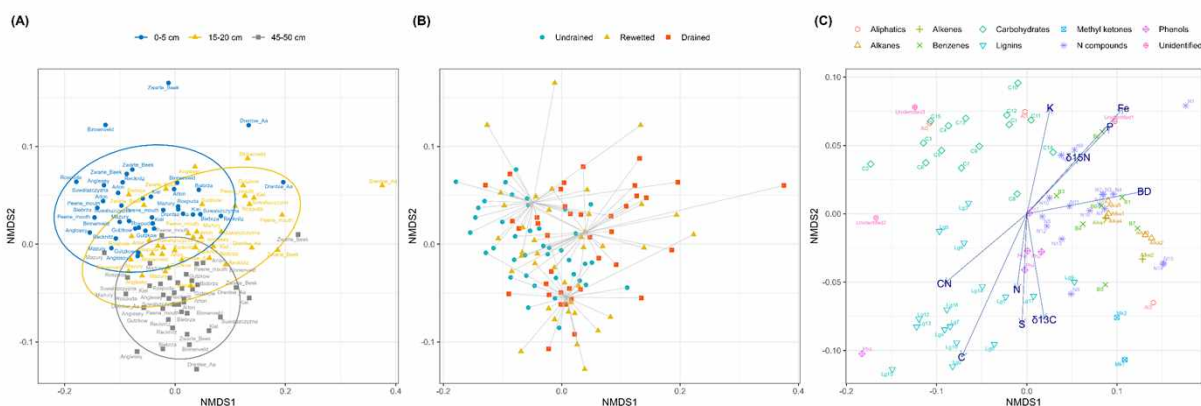

K. KIM<sup>1</sup>, J. SCHELLEKEN<sup>1</sup>, W.J. ESENS<sup>2</sup>, B. JANSSEN<sup>3</sup>, K. VANCAMPENHOUT<sup>1</sup>

<sup>1</sup> Division of Forest, Nature and Landscape, Department of Earth and Environmental Sciences, KU Leuven Campus Geel, Geel, BELGIUM

<sup>2</sup> Centre for Research and Conservation, Royal Zoological Society of Antwerp, Antwerp, BELGIUM

<sup>3</sup> Institute for Biodiversity and Ecosystems Dynamics (IBED), University of Amsterdam, Amsterdam, THE NETHERLANDS

Peatlands degradation has been severely manifested due to intensification of human activities across western Europe. In order to retrieve these ecosystem to the original state that possibly serves multi-functionalities, rewetting restoration has been initiated by maintaining water table. However, it still remains elusive how rewetting restoration shifts peat organic matter (OM) chemical composition. Peat OM chemical composition not only indicates decomposability, but it also regards as footprint to the undergoing hydrological state and vegetations. This research is aimed to characterize if rewetting itself enables to recover peat OM chemical compositions to the original state. To evaluate the effect of rewetting, we compared peat OM chemical compositions across three contrasting hydrological regimes (undrained, rewetted, and drained) at three depths (0-5, 15-20, and 45-50 cm). In addition, our study implemented stoichiometric assessments encompassing elemental analysis, and stable isotope. In pairwise comparison analyses, peat OM chemical composition similarity between rewetted vs. undrained is significantly different, but not between rewetted vs. drained ( $P < 0.05$ ;  $P > 0.05$ ). Drainage significantly increases relative abundances in N compounds, benzene, aliphatic, and decreases relative abundances in carbohydrates, phenol compared to relatively intact one ( $P_s < 0.05$ ). This result enables to further infer that primary shift drivers as a function of vegetation alterations and oxic-anoxic interface condition. Particularly, peat OM chemical compositions at a depth of 15-20 cm went through the most length trajectory compared to other two depths, and there is no significant difference at a depth of 45-50 cm across hydrological regimes ( $P_{15-20\text{ cm}} < 0.05$ ;  $P_{45-50\text{ cm}} > 0.05$ ). By linearly plotting rewetting period to dissimilarity distance, it is estimated that recovery time windows of peat OM chemical composition is about approximately 30 years. These findings suggests that peatlands hydrology is a key driver to alter peat OM chemical composition, and also rewetting restoration itself for several decades is not sufficient to successfully return to its original selves.

#### LONG-TERM EFFECT OF ASH FERTILIZATION ON SOIL MICROBIOME IN DRAINED PEATLAND FORESTS

M. KATTILAKOSKI<sup>1</sup>, J. HULTMAN<sup>2</sup>, K. PELTONIEMI<sup>2</sup>, P. OJANEN<sup>2</sup>, P. VÄÄNÄNEN<sup>2</sup>

<sup>1</sup> University of Helsinki, Helsinki, FINLAND

<sup>2</sup> Natural resources institute Finland, Helsinki, FINLAND

In Finland, fertilization of drained peatland forests with wood ash is one of the actions in the climate plan for the land use sector aiming to improve annual carbon capture. Wood ash is known to increase tree growth but its effects on overall greenhouse gas balance and soil microbial communities are not yet fully understood.

The aim of this research is to investigate how ash fertilization affects the structure, diversity, and functional gene pool of microbial communities in drained peatland forests. Additionally, we explore how the potential changes in the microbial community impact soil carbon storage and which microbial groups participate in the greenhouse gas cycle in drained peatland forests.

The experimental design consists of eight peatland forest sites in Finland representing three drained peatland forest types with varying nutrient levels. Each site has an ash fertilized plot and an adjacent unfertilized control plot. The sites have been fertilized (5 tons of wood ash per hectare) at different times; the oldest in 1937 and the most recent in 2014. Whole community DNA was extracted from a total of 192 soil samples, followed by metagenomic sequencing and analysis.

Based on our results, the ash treatment has an effect on microbial communities when examined on individual sites. However, simultaneous comparison of all sites indicates that site and peatland forest type may have a greater impact on the structure of microbial communities than ash treatment. The effects of ash fertilization on the functional gene pool of the microbial communities are currently being investigated.

**Keywords:** Drained peatland forest, Soil microbiome, Ash fertilization, Soil carbon storage, GHG balance

Africa's potential for scientific research is not yet being realised, for various reasons including a lack of researchers in many fields and insufficient funding. Strengthened research capacity through doctoral training programmes in Higher Education Institutes (HEIs) in Africa, to include collaboration with national, regional, and international research institutions, can facilitate self-reliant and sustainable research to support socio-economic development. In 2012, the Royal Society (RS) and the UK's Department for International Development (DfID) (now the Foreign, Commonwealth and Development Office, FCDO) launched the Africa Capacity Building Initiative (ACBI) Doctoral Training Network which aimed to strengthen research capacity and training across sub-Saharan Africa (SSA). The ACBI supported 30 core PhD scholarships, all registered/supervised within African HEIs with advisory support from United Kingdom (UK)-based institutes. Our "Soil Geochemistry to Inform Agriculture and Health Policies" consortium project which was part of the ACBI doctoral training program network, was implemented in Malawi, Zambia, and Zimbabwe between 2014 and 2020. The aims of our consortium were to explore linkages between soil geochemistry, agriculture and public health for increased crop productivity, nutrition and safety of food systems, and support wider training and research activities in soil science. Highlights from our consortium included: (1) the generation of new scientific evidence on linkages between soils, crops and human nutrition; (2) securing new projects to translate science into policy and practice; (3) maintaining sustainable collaborative learning across the consortium. Our consortium delivered high quality science outputs and secured new research and doctoral training funding from a variety of sources to ensure the continuation of research and training activities. For example, follow-on Global Challenges Research Funded (GCRF) Translation Award provided a strong evidence base on prevalence of deficiencies in children under five years of age and women of reproductive age in Zimbabwe. Although our project and the wider ACBI has contributed to increasing the self-reliance and sustainability of research within the region, many challenges remain, and ongoing investment is required.

<sup>1</sup> Natural Resources Institute. University of Greenwich., Chatham, UNITED KINGDOM

<sup>2</sup> UNITED KINGDOM

<sup>3</sup> UNITED KINGDOM

Since women represent 43% of the global agricultural labour, food security research is moving towards a multi-disciplinary approach where gender has a growing importance. But assuring food security is not possible with an unhealthy soil incapable to support crop production. However, there is little research in soil health under a gender framework. In 2021 a systematic literature review was conducted using Web of Science aiming to determine the type and extent of evidence reporting soil health differences between plots farmed by men and women. 54 articles were involved, mostly based on African countries. Only 7 articles used quantitative data measuring soil health indicators between plots farmed by men and women, with no generalisable conclusions. This scarce evidence may be related to the prominence of shared farming systems and the difficult to establish a gendered division within them. The rest of the articles used mixed quantitative and qualitative data collected through questionnaires and discussed the adoption of soil enhancing technologies among women. Their findings suggest female farmers are less likely to adopt capital intensive practices because of a limited access to loans. In circumstances where households are financially secure, women then will choose the less labour-intensive practices because of a restricted labour availability due to different causes, such as a reduced number of working age members in their households or social norms about the tasks they are allowed to do. However, the survey processes used here were not clear or accurate. For instances, there is no description if women were interviewed separated by men, and if their answers were influenced by their presence.

Finally, the reviewed articles discussed soil health functions as nutrition or land degradation but did not discuss functions like soil biology and the regulation of pests and diseases. Summarising, the review unveiled many research opportunities. Future works should analyse the labour division patrons, provide detailed surveys, and explore other soil health functions, specially in countries outside Africa.

### SOIL HEALTH IN NEPAL'S TERAI REGION: USING MENTAL MODELS TO EXPLORE PERCEPTIONS AND PRACTICES

B. HORNE<sup>1</sup>, V. EORY<sup>2</sup>, T. BEGHO<sup>2</sup>, A. GATHORNE-HARDY<sup>1</sup>

<sup>1</sup> University of Edinburgh, Global Academy of Agriculture and Food Systems (GAAFS), Edinburgh, UNITED KINGDOM

<sup>2</sup> SRUC - Scotland's Rural College, Rural Economy, Environment & Society (REES), Edinburgh, UNITED KINGDOM

Soil fertility decline in Nepal's Terai region is a growing concern among agricultural stakeholders. Soil organic matter levels have fallen to critically low levels in 95 per cent of cropland, contributing to declining yields and increasing vulnerability to climate change. Management practices such as deep tillage and crop residue burning are cited as contributory factors to human-induced soil degradation. Correspondingly, rhetoric exists in policy and research organisations that soil degradation is a mismanagement problem. Farmers are blamed for poor decision-making because they purportedly lack knowledge, awareness, and support for soil management. From this perspective, one solution to soil degradation is to educate farmers on best practices. However, questions such as what constitutes "good" soil health; who defines "best" practice; and whose knowledge is considered legitimate and credible, can result in conflicting approaches to soil management. Considering these questions is critical because the responses can shape the way issues such as soil degradation are perceived, the responses deemed appropriate, and the specific land management goals that may be pursued. Intersectional issues such as gender, age, and education may also play a critical yet understudied role in peoples' environmental management decision-making. Exploring these themes, this project will apply a mental model approach to investigate the diverse ways in which soil health is conceptualised, assessed, and practised in the Terai. A mental model represents someone's thoughts about how something works in reality. Data will be collected through interviews with farmers and other stakeholders, focusing on their experience of soil degradation, as well as socio-demographic factors that may influence their approach to soil management. As data collection is ongoing, this presentation aims to stimulate the research agenda by summarising key literature, highlighting gaps, and exploring the application of mental models to understand divergent perspectives and practices. Understanding these different viewpoints holds implications for comprehending, advocating, and targeting sustainable soil management support in the future.

### SOIL STATUS AND ITS RELATIONSHIP WITH GENDER AND HEALTH INEQUALITIES IN GUATEMALA

K. MOLINA GALINDO

The University of Edinburgh, Edinburgh, UNITED KINGDOM

This research examines the relationship between soil inequalities, gender disparities, and health outcomes in Guatemala. The historical context of land concentration, limited access to land, internal conflict, and socioeconomic factors contribute to soil inequalities, which in turn affect household gender dynamics and health outcomes.

Using a case study approach in San Martin Jilotepeque, Guatemala, this research examines the challenges faced by male and female farmers in managing their soil. The study employs a mixed-methods approach, including field observations, surveys, and a literature review. A total of 250 surveys were conducted, gathering information on managing practices in homefield and outfield areas, as well as the gender of field managers and household heads.

Preliminary findings reveal the impact of gender inequalities in land management and access to agricultural resources affect soil quality. Women often experience limited access to agricultural resources such as fertilizers, improved seeds, and machinery, hindering their ability to improve their soil status. This gender-based resource inequality further exacerbates existing gender disparities in agricultural productivity and household well-being.

By highlighting the connection between soil and gender inequalities, this research contributes to understanding intrahousehold gender dynamics and their connection to health inequities. It aims to provide insights for addressing gender and health disparities in Guatemala. Integrated approaches that consider the multifaceted nature of these challenges are essential for sustainable development and community well-being.

Camelina and Carinata are a promising biofuel crops (rich in fatty acids), suitable for cultivation on marginal (sandy textured) soils. The aim of the presented study was to assess the crop yields of mentioned plants on sandy soils (Brunic Arenosols) and present the overview of soil conditions and minimum fertilization effect on it. The study was conducted at 4 locations in Poland in the growing season of the year 2023. In the case of all fields reduced tillage and application of 30 m<sup>3</sup> of liquid manure was applied, before plant sieve. Plant harvesting took place at the turn of July/August 2023. The soil samples were collected (from 5 points within each fields, up to 100 cm) 1-2 weeks after plant sieve. The following analysis were done in soil samples: soil texture, pH, total organic carbon and total nitrogen content, plant available forms of phosphorus, magnesium and potassium, sum of base cations, hydrolytic acidity, cation exchange capacity and base cations saturation. It is worth to mentioned that the long-term drought was observed during the experiment. The climatic water balance was definitely below 0 (-100 to -200 mm). The highest yield of Camelina seeds (1.2 t ha<sup>-1</sup>) was obtained in the field no. 2, while the highest yield of Carinata seeds (370 kg ha<sup>-1</sup>) was obtained in the field no. 1. In one location due to plant diseases the yield of Carinata was not obtained. In one location due to plant diseases the yield of Carinata was not obtained. Analysis of the tested soil properties showed that the crucial parameter that affect plant growth was soil pH, what directly impacts the nutrients availability. Our study reveals that chosen plant are promising solution for cultivation under harsh environmental conditions, and reduced fertilization.

The research was financed within the project: CARINA - CARinata and CamellINA to boost the sustainable diversification in EU farming systems, within the framework of Horizon Europe. Project no: 101081839.

#### MEXICAN SOIL JUDGING CONTESTS

##### A. BARAJAS-ALCALA

ENES-UNAM, MORELIA, MEXICO

Soil judging contests serve as educational platforms wherein soils are described and classified. In Mexico, five national contests have been conducted, comprising two virtual and three face-to-face events. These contests aim to foster participation, learning, and networking among young students and early-career scientists. Distinguished national and international figures evaluate the events. Over 1,000 participants from 16 Mexican states have engaged in these competitions, facilitating interactions among students, coaches, and experts. This interaction has heightened interest in soil studies, leading to the discovery of potential colleagues and research opportunities. Furthermore, the contest has proven to be an effective didactic method for teaching and learning. In conclusion, national competitions serve as excellent forums for identifying future international representatives, with each edition attracting a growing number of young individuals interested in soil science.

#### SENSITIVITY ANALYSIS OF TWO EROSION MODELS IMPLEMENTED IN AN AGRICULTURAL WATERSHED IN SOUTHWEST FRANCE

L. DUNN<sup>1</sup>, M. LANG<sup>2</sup>, C. FABRE<sup>1</sup>, D. SHEEREN<sup>2</sup>, E. RABOT<sup>3</sup>, M. GUIRESSE<sup>1</sup>

<sup>1</sup> Centre de Recherche sur la Biodiversité et l'Environnement (CRBE), Université de Toulouse, CNRS, IRD, Toulouse INP, Univ, Toulouse, FRANCE

<sup>2</sup> UMR DYNAFOR, Université de Toulouse, Toulouse INP, INRAE, Castanet-Tolosan, FRANCE

<sup>3</sup> INRAE, Info&Sols, Orléans, FRANCE

To address the erosion of cultivated soils, various types of actions are being taken. Infrastructure improvements help slow down the transfer of sediments to watercourses. To prevent processes of soil structure degradation, changes in agricultural practices can also be used. All of these solutions represent a significant cost that must be shared by all stakeholders and planned for the long term. Aware of the challenges, stakeholders in the territories are seeking decision support tools to prioritize actions to be taken.

In order to prioritize actions in the municipalities most at risk, watershed managers of the Save river sought to obtain a map of the erosion risk in the watershed. This watershed of the southwest of France is highly agricultural and affected by soil erosion. To qualify the erosion risk, we used a modeling approach using the widely used model RUSLE and the model MESALES adapted for the south of France. The results of this modeling approach depended on the initial assumptions, particularly the model used. Therefore, we sought to understand the sensitivity of these two models.

While the RUSLE model is empirical and based on measurements made in the 1970s in the USA, MESALES is based on an expert system aimed at prioritizing risk without quantifying soil losses. In both approaches, soil erodibility is not assessed in the same way. While RUSLE considers the partitioning of precipitations between infiltration and runoff, MESALES mainly considers the structural instability of soils due to the abundance of silts. Of course, the model outputs also depend on the quality of input data such as precipitation, land cover, and soil characteristics. The coarse resolution of the available soil maps in the region required aggregating data within the polygons of the map. The final map rendering was therefore affected by the aggregation method used. Managers must be aware of these conditions of use to better convey messages to stakeholders about the required change in practices.

## 2. Soil and humanity 2.02 129339 - The development of Soil Science in the IUSS countries: 100 years of history

### DEVELOPMENT OF SOIL SCIENCES IN JAPAN

T. KOSAKI<sup>1</sup>, K. INUBUSHI<sup>2</sup>, T. FUJIWARA<sup>3</sup>

<sup>1</sup> Aichi University, Nagoya, JAPAN

<sup>2</sup> Tokyo University of Agriculture, Tokyo, JAPAN

<sup>3</sup> The University of Tokyo, Tokyo, JAPAN

Modern soil science was introduced just after the reformation of Japan in 1867 mainly by two German teachers, M. Fesca and O. Kellner. Fesca published the first modern soil map in 1885 and Keller initiated fertilizer experiments in 1880s. Then, their students formed the Foundation of Agricultural Sciences in 1887, based on which the Society of the Science of Soil and Manure, Japan, currently called the Japanese Society of Soil Science and Plant Nutrition (JSSSPN), was established in 1927. The Japanese soil scientists have participated in the major international academic gatherings since the 2nd International Conference of Agrogeology (ICA) at Stockholm in 1910. Two joined the 4th ICA at Rome in 1924 when the ISSS was established.

The academic activities then expanded not only in Japan but to Korea, Manchuria and Inner Mongolia as well as Taiwan and Sakhalin in accordance with a military invasion to China and Southeast Asian countries during WWII. Economic growth of Japan in the 1970s accomplished self-sufficiency in rice production and extended the range of crop to grow, however, a variety of environmental issues came out. The JSSSPN became more actively involved in international activities and hosted a number of international conferences, the most significant of which was the 14th ICSS at Kyoto in 1990. The JSSSPN proposed there a regional organization to cope with the unique issues, e.g. improvement of paddy rice cultivation, for Asian countries and established East and Southeast Asian Federation of Soil Science Societies (ESAFS) in 1991. Since the early 1990s, the research topics have become more related to the global as well as regional environmental issues.

Major achievements in the history of the society may include 1) development of research particularly on paddy soils, volcanic ash soils and soil acidity, 2) consistent commitment to the education for constructing sustainable society, and 3) international cooperation in improving rice production in the developing countries in Tropical Asia, Latin America and Sub-Saharan Africa.

The Soil Science Society of Switzerland (Bodenkundliche Gesellschaft der Schweiz (BGS) / Société Suisse de Pédologie, Società Svizzera di Pedologia (SSP)) was founded in 1975 and will thus celebrate its 50-years anniversary in 2025. Originally founded and mainly supported by academic members, the society always had a practitioner's focus and increasingly has been transformed into an association for soil professionals not only from research institutions, but also from local and national governments or the private sector. The BGS/SSP currently has almost 600 members that are active in soil engineering, mapping, policy making or both fundamental and applied research. The diverse background of its members is also expressed by the multitude of working groups of the BGS/SSP that pursue different aspects of soil classification or soil protection policy, contribute to legal consultations, build a platform for soil related educational material from elementary to high school or to ensure knowledge transfer of most recent digital methods into practical application.

With this contribution we will outline the specific features of the BGS/SSP, summarise the work of prominent Swiss soil scientists and will outline the current and future challenges of soil professionals of the many domains in Switzerland.

**TOPOSEQUENCE: AFTER ALL, WHAT ARE WE TALKING ABOUT?**

**G. ALVES<sup>1</sup>, F.S. OLIVEIRA<sup>2</sup>, A.H.N. SILVA<sup>3</sup>, V.S. SOUZA JUNIOR<sup>3</sup>**

<sup>1</sup> Universidade Federal da Bahia, Salvador, BRAZIL

<sup>2</sup> Universidade Federal de Minas Gerais, Belo Horizonte, BRAZIL

<sup>3</sup> Universidade Federal Rural de Pernambuco, Recife, BRAZIL

Toposequence was initially proposed to characterize the lateral succession of soils on slopes influenced by topography. However, its use has evolved and diverged from its original concept. Our objective was to examine the application of this concept since its inception. To achieve this, we conducted bibliometric analyses of publications in the Web of Science database from 1900 onwards. We identified three primary approaches and associated concepts, whether explicitly stated or implied: one at the regional scale and two at the local scale. Based on our investigation, we propose the following recommendations: a) When adopting a regional approach, terms such as Geomorphic Surface or landscape position should be utilized to address the spatial distribution and genetic implications of soils at this scale. b) Employ the term catena for mapping purposes or when emphasizing taxonomic classification in the series/sequences of soils with soil profiles spaced on slopes. c) When the determining factors of the soil sequence are climatic, biotic, lithological, or chronological, the corresponding terms are climosequence, biosequence, lithosequence, or chronosequence, respectively. d) If dealing with a lateral succession of horizons in a continuum on slopes, resulting from the influence of topography on soil formation and potentially reflecting the contribution of soils to the evolution of the topography, only in this scenario should the term 'toposequence' be applied, reverting to its original concept. This analysis contributes to a nuanced understanding of the evolving usage and appropriate application of toposequence terminology in soil science. <FILE IMAGE='1643\_20240131154951.jpg'>

#### SOIL SCIENCE IN ITALY ACROSS THREE CENTURIES: PROTAGONISTS AND ACHIEVEMENTS.

C. DAZZI<sup>1</sup>, A. BENEDETTI<sup>2</sup>, G. CORTI<sup>3</sup>, E.A.C. COSTANTINI<sup>4</sup>

<sup>1</sup> Italian Society of Soil Science, Palermo, ITALY

<sup>2</sup> Italian Society of Soil Science, Rome, ITALY

<sup>3</sup> Italian Society of Soil Science, Rome, ITALY

<sup>4</sup> International Society of Soil Sciences, Florence, ITALY

The history of science is a useful and powerful tool to make young people acquire not only the knowledge, ideas, and the most important theories that, in certain historical periods, have constituted specific scientific knowledge but, also, the scientific investigation methods as they have been formed and evolved over time.

This communication describes the history of Soil Science in Italy from the nineteen to the twenty-first century, highlighting the main research activities and results carried out by its protagonists. Soil Science in Italy has been carried out by diverse Institutions, belonging to Universities and Research Centres, also in collaboration and with the support of Ministries, mainly Agriculture and Environment, Regional authorities, and the European Union.

Analyzing the evolution of Soil Science in Italy, we can see that it follows a historical thread often made of causes and effects, sometimes simple and banal, but sometimes so complex and cumbersome to be unimaginable. In particular, the '80s and '90s of the twentieth century were the "golden age" of Soil Science in Italy, when soil scientists managed to make a system of fruitful collaboration between the Institutions, with many basic and practical results, among which the creation of several regional soil services. The "golden age" achievements were to many respect the outcomes of the school of Soil Science led by Prof Fiorenzo Mancini and his many fellows, who have been operating all over the country since the foundation of the Soil Science Society of Italy (SISS) in the '50s.

But also former years, namely the two periods that preceded the two world wars are fundamental for understanding the subsequent developments that soil science had in Italy. It was just in this period that the International Soil Science Society was founded in Rome. These facts explain to us, perhaps better than any other historical element, that small variations in cultural systems can subsequently provoke large cultural evolutions, whose effects remain today.

### BEACH DANAT (PEARLS): LET NATURE DRAW FOR US

J. IBBINI <sup>1</sup>, A. MOHAMMED <sup>2</sup>

<sup>1</sup> Hashemite University/Department of Land Management and Environment, Zarqa, JORDAN

<sup>2</sup> Emirates Fine Arts Society, Abu Dhabi, UNITED ARAB EMIRATES

My role as an artist is to create a constructive cultural and artistic dialogue between myself and nature – let nature draw for us. The more you care for nature, the more it will care for you. The more you neglect and destroy it, the more you will see the power of its anger.

My current process began in 1998, when I dug a hole on the beach so that my canvas could be exposed to the seawater and the tides. Along with the canvas, I buried saffron, pomegranates, pieces of rusted iron, and iron filings. After about a week, the chemical and biological processes in nature resulted in oxidation of the iron and other materials, resulting in shapes and color gradations of iron rust. Over a period of 25 years many works of art were produced with different materials, conditions, and time periods. This art was a global addition to the world of visual arts that is credited to the Emirates. In recent works, I have added three colors: black, orange, and turquoise to some paintings.

My objectives are to produce unique contemporary works of art, which is also a form of art therapy. It is a treatment for the soul, a relief for the nerves, a release of negative charges through the steps of producing work, a source of happiness, and interacting with nature. In my presentation, I will emphasize the importance of cooperating with nature to discover, respect and preserve its beauty. It is important to perform continuous research in the field of visual arts to discover and invent new artistic and creative methods from what has come before.

### FUNGAL DIVERSITY AS AN INDICATOR OF SOIL HEALTH IN POST-FIRE FOREST RESTORATION

R. WALLEN <sup>1</sup>, R. JANKE <sup>2</sup>

<sup>1</sup> Goddard College, MFAIA, Plainfield, VT, USA

<sup>2</sup> Kansas State University, Dept. of Horticulture, Manhattan, KS, USA

Twenty years ago, the Cedar fire, one of the largest ever in the state of California, ravaged the city and county of San Diego. One of the hardest hit areas was Cuyamaca State Park, known for natural biodiversity, where almost all the conifers perished. Within a few years the land was covered by shrubs, primarily *Ceanothus palmeri*, or wild lilac. *Ceanothus*, in symbiosis with bacteria, fix nitrogen, an essential nutrient that is often depleted during forest fires, but their dense growth is believed to compete with tree seedlings.

Since the fire, park managers have implemented a controversial policy of clearing the *ceanothus*, followed by controlled burns and replanting of conifers. Some argue that *ceanothus* will naturally disappear over time in a process of secondary succession. Removing the shrubs only further damages an already imperiled ecosystem.

In this project, buried cloth and DNA analysis of soil microorganisms was used to compare an area that was undisturbed since the initial fire, to another site that was cleared, burned, and subsequently replanted with conifers. The fungal DNA data suggests significantly higher biodiversity (Shannon Index) in the undisturbed site. The decomposition of the buried cloth provides visual evidence of the richness of the subterranean environment. When this site is compared to others in the ecoartspace "Soil Dialogues" project, the undisturbed site had one of the highest indices of fungal diversity, and the disturbed site had one of the lowest, though the two sites are on similar soils series, altitude, and latitude.

This exploration is a continuation of an earlier project; "Walking with trees," bearing witness to increasing loss due to urbanization, invasive species, drought, bark beetles and fire. At the intersection of art and science, this project asks the question; "given the multiplicity of challenges facing forests are conventional restoration efforts the best means to regenerate forests for future generations?"

#### A SMART SYSTEM TO SUPPORT AWARENESS ON SOILS AND LAND IN ITALY

F.A. MILETI <sup>1</sup>, F. TERRIBILE <sup>1</sup>, B. BLAZICA <sup>2</sup>

<sup>1</sup> Università degli Studi di Napoli - Federico II, Napoli, ITALY

<sup>2</sup> Jozef Stefan Institute, SLOVENIA

Ecotourism and rural tourism, especially for many inland areas, are activities that can generate significant income and support the rural economy and reinforce the awareness of land and soils of specific territories. Because of their cruciality, the United Nations includes them in the 17th Sustainable Development Goal to be achieved by 2030 (SDG 8.9 and SDG 12). Recently, there has been a strong increase in digital tourism, which, however, is almost exclusively aimed at popular tourist destinations.

This paper aims to demonstrate that a geospatial decision support system (S-DSS), developed on a freely accessible, web-based geospatial cyberinfrastructure (GCI), could provide a valuable operational tool to improve both the tourism offer of inland areas and the awareness of land and soil environmental resources.

The S-DSS platform supports the acquisition, management, processing and analysis of both static (e.g. soil, geology) and dynamic (e.g. daily climatic data) data, together with data visualization and on-the-fly computer applications and is designed to support a multi-user community (farmers, tourism businesses, associations and public bodies).

The S-DSS tool known as EcoSmarTour works on the entire Italian national territory and can return a large amount of information (including soils) that will improve knowledge of the territory, manage scenario analysis, produce maps and evaluate potential trails or areas of interest for ecotourism. Furthermore, through the use of artificial intelligence EcoSmarTour can narrate the selected route in text form and does so with a degree of complexity chosen by the user. For instance, this allows to build automatic customized storytelling for children, teenagers, adults or experts. The methodology adopted is highly transferable because it is based on very general algorithms that can be easily applied wherever the necessary data are available.

#### MULTI-ELEMENT PROFILE OF DURUM WHEAT AND PROVENANCE SOIL AS POTENTIAL GEOCHEMICAL FINGERPRINTING FOR GEOGRAPHICAL TRACEABILITY

R. OFANO <sup>1,2</sup>, L. RUGGIERO <sup>1</sup>, D. AGRELLI <sup>1</sup>, E. PIGNOLI <sup>1,2</sup>, C. AMALFITANO <sup>1</sup>, P. ADAMO <sup>1,2</sup>

<sup>1</sup> Department of Agricultural Sciences, University of Naples Federico II, Portici, ITALY

<sup>2</sup> Metrofood-It Research Infrastructure, Portici, ITALY

Ensuring the safety and authenticity of food has become an increasingly complex analytical task over the last decades, mainly due to the globalization of trade in foodstuffs. Agri-products from some geographical regions often command premium prices due to their recognized high quality. There may be an economic incentive to replace or adulterate with cheaper batches of a given product. Multi-element fingerprinting analytical technique has been used to identify the geographical origin of various foods. The aim of this study was to prove the usefulness of geochemical fingerprinting as provenance markers of wheat by evaluating their link with soil composition and their discriminatory power. For this reason, cultivation soils and wheat were collected from various Italian regions during the harvest period. It is known that plant element composition predominantly reflects plant requirements and metabolism, local environmental conditions such as geo-lithology, climate, soil properties, management and their possible interactions. This is why concentrations of mineral elements in wheat and their provenance soils were analyzed by inductively coupled plasma mass spectrometry (ICP-MS). Chemometrics have been implemented for ICP-MS data processing. The relationships of concentrations of these elements between wheat and soil were studied. The elements associated with origin soil were used to discriminate wheat provenance with principal component analysis (PCA) and linear discriminant analysis (LDA). Multivariate analysis demonstrated that origin has significant influences on the content of each element. These findings provide evidence of the validity of multielement profile as marker for the geographic traceability of wheat, and that a geochemical fingerprinting approach can be successfully applied in the development of a database of Italian wheat. In future work, correlation of the element profile of wheat with other soil parameters and climatic factors, need to be investigated to further substantiate the potentiality of multielement for food traceability. Work carried out by METROFOOD-IT (NextGenerationEU, PNRR-M4C2, Investment 3.1-IR0000033 (D.M. Prot. n.120 del 21/06/2022).

**THE DESERT WE EAT: HOW TO DRAW SOIL AS A WAY TO UNDERSTAND FOOD SYSTEMS.**

M. BONVEHI ROSICH

Washington University of St Louis, St. Louis, USA

How we represent soil in design disciplines? This could seem a simple question but in fact is a profound one. Designers: landscape architects, urban designer and urban planners could really benefit to know more about. As designers we get to know things by drawing them but we commonly not know how to draw soil beyond its material presence. As we know soil is also a result of processes that have formed it and continue to transformed. So the question is how can we represent this?

This poster will explain how the importance of understanding an specific site through the act of drawing both the above and bellow of the place itself. This a part of a methodology of an ethnobotany/food systems class focused on the desert landscape of the Mezquital Valley in Central Mexico.

All drawing explorations trace an ingredient and its milieu above and bellow ground. Underground, We seek to produce descriptions of soil that acknowledge the full range of human and non-human desire that participates in the process of the soil's formation and, for ethical reasons, we want to produce this portrait of the emergence of the soil's identity. Above ground, We seek to represent all entanglements that depict the ecological relationships of the ingredient (plant or animal) with its own environment and the limits of it.

In conclusion, this poster will show the approach of how to represent holistically a place by taking apart all its relationships and put them back together, with specific emphasis on soil.

### POETRY AS A TOOL FOR SOIL EDUCATION

P.H. RIBON OGERA <sup>1</sup>, A.A. RIBON <sup>2</sup>, E. D.R. DA SILVA DUARTE <sup>3</sup>, J.G. RETZLAF DE OLIVEIRA <sup>4</sup>, L. OLIVEIRA RIBEIRO <sup>5</sup>, G. DIAS DE SOUSA <sup>6</sup>

<sup>1</sup> State University of Goiás, University Campus of Palmeiras de Goiás, Palmeiras de Goiás, BRAZIL

<sup>2</sup> State University of Goiás, University Campus of Palmeiras de Goiás, Palmeiras de Goiás, BRAZIL

<sup>3</sup> Federal University of Roraima, Boa Vista, BRAZIL

<sup>4</sup> State University of Northern Paraná, Cornélio Procópio, BRAZIL

<sup>5</sup> State University of Londrina, Londrina, BRAZIL

<sup>6</sup> FACMAIS, Palmeiras de Goiás, BRAZIL

Since the production of texts, with an emphasis on poetry, contributes to the awakening of sensitivity, to the formation of the imaginary and the symbolic in people, as well as creativity, and helps in the observation of experiences lived in everyday life, especially among children, the idea arose to give new meaning to this literary genre through themes that have been little explored. In this sense, in the search for interdisciplinarity, writing poetry allows us to combine the stimulus to awaken children's habits and pleasure regarding writing and the construction of the concept of soils. Thus, the Profiles, Soils and Poetry Extension Project developed at the State University of Goiás - Palmeiras de Goiás Campus promotes activities related to the construction of the concept of soils (workshops, short courses, teaching exhibitions) to evaluate students' perception through poetry writing. The methodology of this project consists of, firstly, a work related to the dissemination of knowledge and information related to the soils, and secondly, poetry reading and writing workshops, to familiarize students with poetic writing, with an emphasis on the soil sciences. Thus, through the project, poems become tools that facilitate the teaching and learning process of basic education students, helping to understand soil concepts and allowing for a greater interaction between those involved in teaching, extension and research projects and society, in addition to strengthening the teaching-research-extension tripod within the University. As a final result, the project holds annual poetry competitions, with the soil as a main theme, and organizes books with the participants' literary productions.

### DIGGING IN THE DIRT: SEARCHING FOR EFFECTIVE TOOLS AND LANGUAGES TO PROMOTE SOIL AWARENESS AND VALORISATION

M.C. MOSCATELLI, S. MARINARI

Dept. for Innovation in Biological, Agro-food and Forest systems, University of Tuscia, Viterbo, ITALY

Although soils undergo degradation processes worldwide, it seems that the general public has not a clear perception of this important global environmental issue. There is a lack of effective communication tools that can vehicle soil instances throughout common citizens. Being a hidden resource, not particularly attractive, soils are not perceived for the functions they perform and are generally ignored. In most cases soils are considered a mere inert surface without including the three-dimensional properties that comprehend their numerous and precious functions. Furthermore, the tight relationship between humans and soils has been lost with time leading to the current unawareness. Hence, a change of perspective and language is necessary if a larger public needs to be reached with the aim to increase soil literacy. It is imperative to propose additional viewpoints and attributes aimed to enhance soil perception among the general public that could, ultimately, foster valorisation and consequently protection.

Starting from the recently proposed soil security concept, introducing additional pillars (the five Cs) for securing soil, the contribution focuses on connectivity as a social dimension dealing with communication. In particular, the aim of this contribution is an attempt to focus on the likely factors underlying the contemporary common disregard towards the soil resource, then it will encompass semantics issues, analyse new attributes, discuss ethical behaviour and, finally, propose new communication tools. A specific focus on visual arts is included as art shows a great potential for utilising global issues as content for artworks, particularly when the concept to be communicated is difficult to convey and perceived by a wider public which is definitely the case of the soil resource. Finally, different branches of human sciences can play a central role for an effective communication of scientific issues because they hit the emotional, sensitive, intimate side of humans going beyond the conventional language of science that is almost unknown to the general public.

### CULTIVATING CONNECTIONS: SOIL'S PRESENCE IN LITERATURE

R. PLEBISCITA

UNIVERSITA' D'Annunzio, Pescara, ITALY

The concept of soil, either considered as such or extended to land, is present in literature in all languages, as novels, essays, traveler writings, and even as poetry. Although soils are seldom acknowledged as individual objects, their meanings as indispensable resources for food production, recycling of materials, hydrological regulators, and witnesses of history and cultures, among other ecosystem services, are implicit in many literary works. This symposium welcomes contributions showing representations of soils by writers, in any language, that are hidden in their works, which may become compelling tools to increase awareness of the value of soils in our societies. The potential contributors are soil scientists reporting literature or writers with a certain awareness of the value of soil and land.

**PLURALISING SOIL HEALTHS – EXPERIMENTING WITH ‘OPENING-UP’ TYPES OF SOIL ENGAGEMENT AMONGST DUTCH FARMER-PRACTITIONER-SCIENTIST COLLABORATIONS**

D. STOMPH

Cultural Geography group, Wageningen University, Wageningen, THE NETHERLANDS

This paper presents work-in-progress of PhD research on how soil might be known, treated, and experienced differently when foregrounding soil health. Could work on soil health by farmers, trainers and scientists be seen as part of an emerging alternative ethics? Can they forge new types of relations with soils and if so, how?

This paper is based on ongoing ethnographic fieldwork within farmer-practitioner-scientist collaborations on stimulating and understanding soil health of Dutch peat grasslands. The paper introduces the context of the collaboration on soil health by illustrating: scientists attempts and debates on how they can know and measure soil health, farmers seeking to experience and stimulate soil health, and regenerative agriculture advisors in their role as interlocutors between generic knowledges and situated understandings of soil health. The shared quest their work responds to is how they can support soil health. These collaborations on the surface seem to narrate a story of role inversion between human and soil, where human actions, knowledges and sensitivities are intended to support soil, rather than that these should further human's capacities of exploiting soil. But is this inversion the only interpretation of the emerging collaboration? Which other stories emerge and how do these stories speak to critical perspectives on human-soil relations and geoeitics?

In seeking to answer these questions, this paper presents a research approach that not merely describes or critiques, but simultaneously aims to be generative. This means that beyond critical insights, I explore alternative trajectories that could augment the existing farmer-practitioner-scientist collaborations. Specifically, by inquiring how rather than existing 'closing down' types of knowing soil health, 'opening-up' types of engagement may be fostered. The paper concludes with reflections on how geo-ethics as a practice, an attitude and sensitivity might become situated in place like the Dutch peat grassland and as such would allow for knowledges that are sensitive to specific and plural ways of relating with soils and in turn with soils' plurality.

**DEVELOPING A SOIL HEALTH AND WELL-BEING INDEX**

F. CLAIRE<sup>1</sup>, C. HAMMOND-WAGNER<sup>2</sup>, H. PEPLINSKI<sup>2</sup>

<sup>1</sup> USDA-ARS Northern Great Plains Research Laboratory, Mandan, USA

<sup>2</sup> USDA-ARS Food Systems Unit, Burlington, USA

Cost-benefit analyses of soil health management practices do not account for well-being outcomes and other intangible benefits of soil health management. Developing an easy-to-grasp number to communicate the well-being outcomes of soil health may help communicate the full range of soil health impacts to producers and policymakers. A multi-step process was used to develop a 5-question index to measure the intangible benefits of soil health management in agricultural systems. First, a soil health and well-being framework was inductively developed through interviews with producers. Over 300 potential items were then developed within each domain and sub-domain of the framework to capture intangible benefits of individual subjective and community well-being. The 300 items were then reduced to 80 by eliminating redundancy, lack of clarity, lack of ability to create a range of responses, and context-specific statements. A two-stage iterative Delphi panel of soil health professionals (n=10) provided feedback via an online survey and then a follow-up interview on the content validity of the statements. Between the two rounds of the Delphi panel, the items were clarified, new items were added to increase the dimensionality of constructs and reduce overlap between constructs. Next, pre-testing of questions with producers (n=8) via cognitive interviews was conducted to improve the face validity of the statements. Finally, the index was administered to a sample population (n=400) at two time points (3 months apart). The answers were analyzed for reliability, tests of dimensionality, and statement reduction. The resulting 5-item soil health and well-being index was developed for use with agricultural producers.

**TOWARD A RELATIONAL LAND ETHIC: FROM LEOPOLD TO RELATIONAL MATERIALITY**

K. LAWLESS

Huron University, London, CANADA

The global polycrisis is one of compounding wicked problems, most of which are related to the battle for finite land and resources. Clearly, we need new ways of approaching this increasingly acute plight that move beyond the usual siloes. Transdisciplinary research facilitates deep integration across not only disciplines, but social divides as well. Tackling the proverbial land question (which must include the resource question) from the vantage point of multiple and braided knowledges at the planetary scale requires a systematic ethical framework that serves not only as a guide for developing reciprocal social-ecological relations, but also as a foundation for high-level policy decisions.

This paper proposes the development of a relational land ethic that weaves relational materiality into Leopold's famous land ethic (1949). Land here is seen as community enfolding all biota embedded in their evolving common habitat and implies a continuum across space and time. Scholars working at the intersection of soil science, social science, and humanities, such as Krzywoszynska and Marchesi (2019), have called for a relational materiality approach that effectively bends the curve of economic growth and environmental degradation by generalizing nature under the sign of ecological (instead of extractive) value. This is not so different from Leopold's assertion that humans, as a part of nature rather than its master, must recognize nature's intrinsic value and limit their own freedoms where they impinge on nature's continuity. Leopold, however, offered no clear and abiding framework for his land ethic. Hence, I see it as the work of scholars working at the intersections of soil science, social science, and humanities to not only develop this framework, but also use it to inspire a planetary vision that is wide-ranging in impact, from informing policy and instituting resource security to birthing new modes of perception and imagining new ways of living together, some perhaps already foreshadowed by ancient Indigenous worldviews (e.g., Buen vivir; see Bjork-James et al. 2022).

### THE POSITIVE EFFECT OF COMPOST AGAINST URBAN SOIL COMPACTION

B. ROMPATO<sup>1,2</sup>, G. MASTROLONARDO<sup>2</sup>, G. CERTINI<sup>2</sup>, M.T. BARRAL<sup>1</sup>, R. PARADELO<sup>1</sup>

<sup>1</sup> CRETUS, Departamento de Edafología e Química Agrícola, Santiago de Compostela, SPAIN

<sup>2</sup> DAGRI, Dipartimento di Scienze e Tecnologie Agrarie, Alimentari, Ambientali e Forestali, Firenze, ITALY

Urban waste management and recycling are important issues for the sustainability of cities. Although current uses of composted urban wastes are mostly oriented towards rural land applications, they can also be used successfully within the cities for the restoration of degraded soils. In this work, urban waste composts were assessed as amendments for the reconstruction of urban soils degraded by compaction, where plant growth is hindered. Three soil-like materials –excavated subsoil, construction sand, and crushed construction/demolition waste– were blended alternately with each of three types of composts –green waste compost, food waste compost and municipal solid waste compost– at 20% weight. Imported topsoil, currently used for the remediation of compacted areas by the University of Santiago garden service, was employed as a control. The mixtures were characterized for their main physicochemical properties, and the influence of compost on susceptibility to compaction was assessed preparing compaction curves by the Proctor standard test. The results show that the addition of each of the composts increased the fertility and water retention of all the earthy materials, and reduced their susceptibility to compaction, in some cases even improving the properties of the control soil. The mix of excavated subsoil and green waste compost presented the least susceptibility to compaction, whereas the mixtures with sand presented the poorest properties. Testing the performance of the materials with the best properties under field conditions will be the next step necessary to assess the use of compost for remediation of compacted urban soils.

### HEAVY METAL BACKGROUND IN URBAN SOILS OF BARCELONA (CATALONIA, SPAIN)

E. TENA, S. MANGAS, N. ROCA

BECCA dept., Fac. of Biology. Universitat de Barcelona., Barcelona, SPAIN

Heavy metals are prevalent in urban environments due to rapid urbanization and industrial development. The main objective of the current study is to assess the contamination status and spatial distribution of heavy metals in urban soils from the Barcelona city in Catalonia, Spain. For this purpose, a total of 41 urban topsoil (0-15 cm) and subsoil (15-30 cm) samples were collected, and eight heavy metals were analyzed, including arsenic (As), cadmium (Cd), chromium (Cr), cobalt (Co), copper (Cu), nickel (Ni), lead (Pb), and zinc (Zn). Considering the need to find a simple and robust statistical test, the calculated distribution function was used. The upper limits of the background ranges were expressed in mg kg<sup>-1</sup>: As 27.9, Cd 13.1, Co 17.2, Cr 145.5, Cu 103.8, Ni 48.1, Pb 258.2 and Zn 426.6. Once the background upper limits were established, some points with anthropogenic signatures were observed. The greatest enrichment anomalies in Cu, Pb and Zn were detected in a small urban area between buildings in Sants neighbourhood that was occupied by a metal smelting industry in the last century. Another enrichment point (As, Co and Zn) was an urban park occupied by shacks made of asbestos materials during the 1960s. Moreover, in the metropolitan area of Barcelona, there are still areas with strong industrialization such as Sant Adrià del Besòs with enrichment anomalies in Co, Cr, Cu, Pb and Zn. Anova test showed significant differences between uncontaminated urban Technosols and in situ developed soils for the contents of Cd, Co and Cr. The Geoaccumulation Index indicated that 75% of contaminated soil samples are in range of slightly contaminated samples, and only 3% are extremely contaminated. The study allowed to verify the heterogeneity of metal content values in the city's soils and their dependence on urban characteristics and historical use.

**GIANCARLO DE CARLO: ENVIRONMENT IS EVERYTHING. A RETROSPECTIVE FOR THE FUTURE**

A.A. CLEMENTE

Università degli Studi G. d'Annunzio Chieti Pescara, Pescara, ITALY

In the last two decades of Giancarlo De Carlo's academic and professional career, the theme of the environment has taken on a significant role. It has sparked a fertile line of research aimed at a deep revision of urban planning methodologies. Multiple in-depth analyses. Three are the main ones. The first one concerns an interview from 1987, where De Carlo wonders whether "a new discipline that deals with the environment and includes urban planning as a specific case" is necessary. The second one concerns an essay from 1991 titled "It's Time to Turn the Telescope". The thesis is radical: "the environment is everything: territory, landscape, countryside, urban outskirts, cities, historic centers, buildings, squares, streets, etc., are specific cases within the environmental universe". The third is retrospective and concerns the exhibition dedicated to De Carlo at the MAXXI in Rome in 2005: "Turning the telescope upside down meant freeing oneself from certain distortions, such as building in blocks rather than sequences of landscapes".

The question posed pertains to the relevance of this research direction today. A challenging thesis to support, considering the limited attention it received during the centenary of De Carlo's birth. However, when looking at the ability to reflect on the city, reinterpret notions of urban soil and territory, and reformulate research questions, as happened in the Urbino Urban Plan in 1994, De Carlo's legacy represents an extraordinary asset for urban planning. This legacy follows four priority lines of action: the interdependence of all components of the territory, ecology, landscape, and transdisciplinarity. It deserves to be revisited. Not only for historical-cultural interest but also as a contribution to the greatest challenge that urban planning must face: combating climate change. De Carlo's foresight, even today, struggles to become common awareness: "Destruction of a forest is not only an ecological crime but is simultaneously and correspondingly a geographical, geological, topographical, landscape, architectural crime". Yesterday an intuition, today a possible new beginning.

### WELL-MANAGED URBANIZATION COULD HALVE NITROGEN POLLUTION IN CHINA

D.O. DENG<sup>1</sup>, B.J. GU<sup>1</sup>

<sup>1</sup> Zhejiang University, Hangzhou, CHINA

<sup>2</sup> Sichuan Agricultural University, Chengdu, CHINA

Halving nitrogen pollution is crucial for achieving sustainable development goals (SDGs). However, how to reduce nitrogen pollution from multiple sources remains a grand challenge. Here we show that reactive nitrogen (Nr) pollution could be roughly halved by well-managed urbanization in China by 2050, with emissions of NH<sub>3</sub>, NO<sub>x</sub> and N<sub>2</sub>O to air declining by 44%, 30% and 33%, respectively, and Nr to water bodies by 53%. Urbanization shifts population from rural to urban areas and promotes large-scale and crop-livestock coupled farming, which reduces non-point source pollution from rural sewage and agriculture. Although rural-to-urban migration increases point-source nitrogen emissions in metropolitan areas, regional air and water quality can be improved by reducing upstream and regional total Nr losses, with increased opportunities to control of point source emissions vs. diffuse emissions. Approximate US\$ 61 billion would be required for additional urban waste treatment, agricultural land consolidation and livestock relocation, as well as upgrading industrial facilities. However, the overall benefits are calculated at US\$ 245 billion due to increases in agricultural productivity and improvements in environmental quality. Such a large benefit-to-cost ratio suggests the feasibility and cost-effectiveness of halving Nr pollution through urbanization, and this would make significant contributions to achieving several SDG targets.

### REFLECTIONS ON URBAN EXPANSION AND AGRICULTURAL SOIL

L.M. LUIS MARINO SANTANA RODRI

UNIVERSIDAD DEL VALLE, CALI, COLOMBIA

Scientific and professional communities from different fields represent nowadays a significant challenge in proposing appropriate forms of territorial occupation. According to multiple researchers, the interactions between society and nature, manifested in diverse land uses, lack harmony when contrasted with the land's inherent potential. This is leading to unsustainable situations of ecosystem services in the environment which ultimately has a negative impact on society. The most dramatic manifestation of the above mentioned is expressed, to a large extent, by the exponential growth of the global urban population. According to the UN, the urban population currently reaches 57%, with Latin America facing a more critical scenario where 81% of the population lives in cities and urban settlements. The session titled, "Soil for Planning Sustainable Cities" reflects one of the primary concerns that soil researchers and specialists from different fields engaged in urban development and planning should address. The predominantly horizontal urban expansion phenomenon has led to the degradation of soils with significant agricultural potential and the compromise of other ecosystem services essential for human life. This work intends to underline the importance of understanding the land's potential, aligning it with Colombian policy on rural land occupation, providing technical insights to preserve rural areas with an agricultural vocation in territorial ordinance plans, and serving as a guarantee of sustainability and life.

### REUSING REMOVED ASPHALT IN DESEALED SOIL TO REDUCE DISMANTLING COSTS

G. FANTONI<sup>1</sup>, B. ROMPATO<sup>1</sup>, G. MASTROLONARDO<sup>1</sup>, R. PARADELO NUÑEZ<sup>2</sup>, G. CERTINI<sup>1</sup>

<sup>1</sup> University of Florence (UniFi)-Department of Agriculture, Food, Environment and Forestry (DAGRI), Florence, ITALY

<sup>2</sup> Universidade de Santiago de Compostela-Department of Soil Science and Agricultural Chemistry, Santiago de Compostela, SPAIN

The practice of permanently covering soil with impervious material such asphalt and concrete (soil sealing) increased exponentially since the industrial revolution, crippling soil ecosystem services. As a result, soil sealing represents a compelling danger on sustainability, at both local and global scale. At the dawn of the new millennium, efforts to convert this trend are due and are actually being carried out, although on a still too limited surface. Desealing (or depaving) has shown enormous potential for recovering new surfaces to plant growth and other soil ecosystem services. However, soil desealing is not as simple as it may appear. In addition to technical and legal issues, high practice costs and material disposal refrain the attempters, who usually are public administrations. To individuate a cheaper alternative to landfill disposal and favouring the reuse of anthropic wastes, we studied the effects of incorporating the removed asphalt, once suitably crumbled, into the desealed soil to be used as a green area.

The experiment is underway, in situ, in a former parking lot in Prato, Italy, which has been dismantled and transformed into a public park. In a fenced part of the meadow, the performances of four different blends of urban soil, compost (5% everywhere) and asphalt in different proportions (up to 50%) to the soil, are going to be monitored for at least one year in terms of physical, chemical and biochemical properties evolution, as well as supported microbial, animal and plant biomass, activity and diversity. Here, we present some preliminary results.

### IDENTIFYING RESEARCH PRIORITIES TO ACHIEVE NO NET SOIL SEALING IN THE EU POLICY FRAMEWORK

C. CORTINOVIS, S. FREZZI, D. GENELETTI

University of Trento, Department of Civil, Environmental, and Mechanical Engineering - Trento - Italy, Trento, ITALY

This contribution presents the preliminary results to identify knowledge gaps and research priorities to achieve the EU's no-net soil sealing and land take targets. The work is undertaken within the project SOLO - Soils for Europe, funded by the EU Soil Mission. The methodological approach is based on a scoping review of the scientific and grey literature, combined with facilitated discussions with a team of experts (Think Tank), and input from a group of peer-reviewers. Based on the identified knowledge gaps, during the next four years, the project will iteratively refine a research and innovation roadmap for soil health in Europe, aimed at guiding future funding priorities at EU level.

The poster introduces the participatory approach adopted by SOLO and the opportunities for contributing to the ongoing roadmapping exercise. It then presents the identified knowledge gaps related to soil sealing, land take, and urban land recycling; and discusses the results of the first round of scoping review and consultations.

The identified knowledge gaps span from gaps related to the technical dimension, such as methods, data, and indicators to map and classify sealed and unsealed soils; to gaps related to actions and policies to counteract soil sealing, including legal and societal aspects. Among others, the Think Tank discussed the lack of suitable data and homogeneous approaches to track changes in soil sealing associated with small sealing interventions such as those in urban domestic gardens, as well as the need to overcome a binary classification of sealed vs unsealed soils towards a classification system that explicitly accounts for soil properties and functions.

Discussions around the poster will provide the opportunity to further elaborate on the list of gaps, including other perspectives not yet integrated in the participatory process, and to collect opinions about priority gaps to be addressed to support the ambitious European objective of 100% healthy soils by 2050.

### URBAN GARDENS IN FOOD SECURITY AND SUSTAINABILITY: A STUDY IN THE PAULO FREIRE OCCUPATION, BELO HORIZONTE, BRAZIL

A.M. COSTA<sup>1</sup>, J.G. SILVA<sup>2</sup>, M.S. MOURA<sup>3</sup>, F.A.L. PACHECO<sup>4</sup>, L.F.S. FERNANDES<sup>5</sup>

<sup>1</sup> Federal University of Minas Gerais, Belo Horizonte, BRAZIL

<sup>2</sup> Federal University of Minas Gerais, Belo Horizonte, BRAZIL

<sup>3</sup> Federal University of Minas Gerais, Belo Horizonte, BRAZIL

<sup>4</sup> University of Tras-os-Montes and Alto Douro, Vila Real, PORTUGAL

<sup>5</sup> University of Tras-os-Montes and Alto Douro, Vila Real, PORTUGAL

Urban gardens play a vital role in the food security of communities in large urban centers, as well as providing a source of income and leisure for marginalized populations, such as in settlements. The common use of organic waste from composting by small farmers often lacks technical guidance and is guided by local knowledge. Understanding the composition of waste and soils is crucial to identifying nutrients or contaminants that affect soil health, productivity and, consequently, the health of the population. The physical and chemical characteristics of the soils in horticultural beds, extensions for agriculture, at the Paulo Freire occupation in Belo Horizonte, MG, Brazil, were evaluated. The area comprised four 10x30m beds, growing lettuce, cabbage, spring onions, mustard and medicinal plants. Soil samples were collected at two depths (0-20 cm and 20-40 cm) and analyzed for texture, fertility, soil organic matter content and compost. The soils ranged from sandy loam to sandy loam, with averages of 26.8% clay, 44.3% silt and 28.9% sand. They had an alkaline pH, at the limit of suitability for vegetables. Plant nutrients (Ca, Mg, K and P) were high, reflecting the abundance of organic material in the beds. Organic matter levels at depths of 0-20 cm reached 15% and 28% at points P1 and P2, respectively. In addition to the economic benefits, urban gardens play a therapeutic and subsistence role, contributing to the goals of the Sustainable Development Goals (SDGs) 2 (Zero hunger and sustainable agriculture), SDG 3 (Health and well-being), SDG 6 (Drinking water and sanitation), SDG 12 (Sustainable consumption and production), SDG 13 (Action against climate change) and SDG 15 (Life on land), which jointly aim for global action to end poverty, protect the environment and climate, and ensure that people can enjoy conditions of peace and prosperity.

### SOIL MAP AS A BASIS FOR MANAGEMENT DECISIONS AT UNAM CENTRAL CAMPUS

S. CRAM <sup>1</sup>, B. PRADO <sup>2</sup>, P. ORTEGA <sup>2</sup>, L. MORA <sup>2</sup>, P. FERNANDEZ <sup>1</sup>, M. CAYETANO <sup>1</sup>, E. CHÁVEZ <sup>4</sup>, M. GUILBAUD <sup>3</sup>, I. QUIJADA <sup>1</sup>

<sup>1</sup> Instituto de Geografía, Universidad Nacional Autónoma de México, Ciudad de México, MEXICO

<sup>2</sup> Instituto de Geología, UNAM, Ciudad de México, MEXICO

<sup>3</sup> Instituto de Geofísica, UNAM, Ciudad de México, MEXICO

<sup>4</sup> Facultad de Filosofía y Letras, UNAM, Ciudad de México, MEXICO

The basis of soil management to ensure that its ecological functions are optimally fulfilled and thus contribute to the quality areas in cities, the most relevant indicator of sustainable cities, is to have cartographic information. In a city, this represents a challenge due to the modification that the forming factors have undergone due to the influence of human activities, which makes it difficult to elaborate a soil map, such as the one required to make decisions on soil management.

This work presents a proposal for the elaboration of a soil map for the central campus of the National Autonomous University of Mexico (UNAM). This map is necessary to apply the actions contained in the Integral Plan for Sustainability (PISU) prepared by the University Coordination for Sustainability at UNAM, which is the guiding document for the consolidation of UNAM as a sustainable university. One of the objectives of the PISU is to promote the adequate management and preservation of soils, green areas and natural reserves, which is why it is very necessary to have a detailed soil map.

This work also intended to lay the groundwork for other UNAM campuses to prepare their respective soil maps. It can also be part of a strategy to train professionals who can later work in the planning of sustainable cities.

### STRATEGY OF THE MEXICAN SOCIETY OF SOIL SCIENCE FOR THE DISSEMINATION AND POPULARIZATION OF THE IMPORTANCE OF SOIL IN THE MEXICAN EDUCATIONAL SYSTEM

R.D.C. CASTELÁN VEGA<sup>1</sup>, J.V. TAMARÍZ FLORES<sup>1</sup>, L. SANTA CRUZ LUDWIG<sup>2</sup>

<sup>1</sup> BENEMÉRITA UNIVERSIDAD AUTÓNOMA DE PUEBLA, PUEBLA, MÉXICO

<sup>2</sup> SOCIEDAD MEXICANA DE LA CIENCIA DEL SUELO, CHAPINGO, MÉXICO

In 2020, the Mexican Society of Soil Science (SMCS) included in its organizational structure the Secretariat of Education and Teaching of Soil Science, whose objective is to link the SMCS with educational institutions and society, in general, to disseminate the importance of this natural resource, generate awareness of its use and sustainable management and promote its conservation. To achieve this, a strategy with four lines of action was generated and executed collegiately, interdisciplinarily, and simultaneously. Axis 1 addresses the issues of education and teaching, through which the National Network for Soil Science Education and Teaching has been created, with 60 researchers from different institutions of higher education who carry out continuous workshops with elementary schools, promoting the IUSS GO TO THE SCHOOL Educational Program; Axis 2 focuses on the elaboration of dissemination material, in which several infographics, agronomic cards and books on the importance of soil have been developed for different educational levels; Axis 3 is in charge of public and educational policy, where several approaches have been made with SEMARNAT and the Ministry of Education to include soil science topics in the curriculum of the educational system. Finally, axis 4 focuses on the annual organization of the Symposium on Soil Science Education and Teaching within the National Congress of the SMCS, which is currently in its XVII edition. In the last Symposium, more than 250 attendees from primary, secondary, and high school education attended, and schools from indigenous peoples participated, exchanging their knowledge on soil management with students from urban areas and science workshops given by soil scientists. The creation of the Secretariat of Soil Science Education and Teaching is significantly promoting the inclusion and dissemination of the importance of soil in the Mexican educational system.

### 2.09 133548 - Microbiome as a common thread from soil to human health: Interaction, Impact and Role of Soil-Plant-Human Microbiome as a new challenge of innovative agriculture and quality food

#### EFFECTS OF TOROCHICK POULTRY MANURE AND BACTERIAL SEED DRESSING ON THE SOIL BACTERIOBIOTA

K. KRUSCIC <sup>1</sup>, T. JANAKIEV <sup>1</sup>, N. ANTIC <sup>2</sup>, S. PREDOJEVIC <sup>3</sup>, V. SCEPANOVIC <sup>3</sup>, I. DIMKIC <sup>1</sup>

<sup>1</sup> University of Belgrade, Faculty of Biology, Belgrade, SERBIA

<sup>2</sup> University of Pristina, Faculty of Science and Mathematics, Kosovska Mitrovica, SERBIA

<sup>3</sup> MIVAKA DOO, Belgrade, SERBIA

Our study aimed to compare the rhizosphere autochthonous bacteriobiota of plants grown from dressed seeds with *Priestia megaterium* M1.5 and seed and soil treated with Torochick poultry manure at standard and double concentration (MIV1 and MIV2) with negative controls. Sampling was carried out at three different times during the season: in May, only the soil was sampled (NK); in June and July, both the negative control (NK1 and NK2) and the soil treated with MIV1 and MIV2 were sampled. The Torochick showed a high diversity in genera such as *Fastidiosipila* (51.36 %), *Corynebacterium* (11.92 %), *Caldicoprobacter* (5.85 %) and the family *Bacillaceae* (3.43 %). However, this abundance did not affect the subsequent composition of the indigenous soil bacterial communities. NK showed a high abundance of *Nitrososphaeraceae* (21.89 %), *Gaiellales* (9.69 %) and *Rhizobiales* (6.91 %), indicating a nitrogen-rich soil. In June, NK1 showed a decline in these taxa, while the biotreatments recovered or exceeded their abundance. The *Nitrososphaeraceae* increased from 4.12 % to 5.12 % and 6.07 %, the *Gaiellales* from 8.94 % to 17.31 % and 14.23 % and the *Rhizobiales* from 6.36 % to 8.68 % and 9.95 %. Similar patterns were observed in July. Some treated samples showed a relative abundance of *Variovorax* above 70 %, possibly related to drought stress. Alpha diversity analyses revealed a generally high diversity in the negative controls and the MIV samples, with slightly higher Shannon indices for MIV1 compared to its negative control. Contrary, the MIV2 samples showed a slight decrease compared to their respective negative controls. PCoA beta diversity analysis grouped all samples, indicating low differential abundance. Notably, the Torochick-only samples showed significant differences in taxa abundance compared to the controls and MIV1/MIV2. According to the statistical data, the yield of MIV1 increased to 9931 kg/ha compared to the negative control (9810 kg/ha), while the yield of MIV2 increased significantly to 9210 kg/ha compared to the negative control (8748 kg/ha).

**SEARCHING FOR SOIL: ELUCIDATING PUBLIC INTEREST IN SOIL AND SOIL CONSERVATION FROM 20 YEARS OF INTERNET SEARCH TRENDS.**

S. BOOTH

University of Nottingham, Nottingham, UNITED KINGDOM

Over the past two decades, soil science has experienced rapid expansion, driven by its crucial role in addressing major challenges such as climate change and food security. Assessing public interest in soil science is pivotal for evaluating the success of dissemination efforts and situating it within broader environmental discourse. This study investigates the trajectory of public interest in soil and soil conservation over a 20-year period using Google Search Trends. Analysing data from 2004-2023, this research aims to uncover temporal patterns in online engagement with soil-related topics, while also exploring potential influences on these trends. Averaged yearly search volume index for search terms related to soil characteristics, conservation practices, and their potential co-influences were produced. Kruskal-Wallis tests with post hoc Wilcoxon rank-sum test to produce year-year pairwise comparisons were conducted. Several significant trends emerged, with searches related to specific soil characteristics displaying stability or gradual increases until 2019, with significant spikes in interest observed in 2019-2020 (carbon, nitrogen, water, erosion) and 2021-2022 (carbon, water, erosion). Searches for 'Soil Health' did not follow this pattern. Interest in soil conservation practices and their links to climate change showed significant increases 2019-2022. Influential factors such as the documentary 'Kiss the Ground' and searches related to climate change and carbon sequestration demonstrated significant increases and peaks in these periods, potentially explaining similar trends in more specific soil-related searches. Searches for "IPCC" did not trend in the same patterns, suggesting their reports are not co-influences on interest in soil and soil conservation. However, searches for "Sustainable development goals" did trend with a number of soil characteristic searches and soil conservation topics, suggesting interest in soil is well linked with the UN's sustainable development goals. This study highlights a significant rise in interest in soil science, likely influenced by dissemination events and broader interest in climate and environmental science. Ongoing communication is key to ensure sustained progress in soil science awareness compared to other disciplines.

#### DIRTY MATTERS – THE SOIL GAME

C. VAN MIDDEN<sup>1</sup>, E. BURAK<sup>1</sup>, N. BERIOT<sup>2</sup>, T. TAPARIA<sup>3</sup>, M. LÖBMANN<sup>4</sup>

<sup>1</sup> Cranfield University, School of Water Energy and Environment, Bedford, UNITED KINGDOM

<sup>2</sup> Wageningen University, Department of Environmental Sciences, Wageningen, THE NETHERLANDS

<sup>3</sup> University of Copenhagen, Department of Biology, Copenhagen, DENMARK

<sup>4</sup> Svensk Kolinlagring, Research and Monitoring, Malmö, SWEDEN

Soil is an integral aspect of several vital functions, services and socio-economic activities, such as biomass production and clean water supply. Consequently, many of the UN Sustainable Development Goals (SDGs) such as SDG 2: food security, SDG 6: clean water, and SDG 13: climate change can be delivered by good soil management. Despite its necessity, there is a general lack of awareness regarding the importance surrounding soil as a resource. With our project, we wanted to make soil literacy and awareness accessible to a wide audience. Our aim was to create a fun and educational boardgame that demonstrates the ability of soils to deliver on these SDGs whilst showcasing the interlinking complexity of the soil ecosystem.

The resulting game is called Dirty Matters: the Soil Game. It focuses on how soil management practises affect soil, which in turn affect the SDGs. Dirty matters is a fully cooperative game where the players embody soil organisms (including the mole, earthworm, and rhizobia) and move around the soil implementing soil management techniques (such as cover crops, no tillage regimes, and adding manure) to counteract events that negatively impact the soil (such as soil compaction, acid rain, and erosion). This is all done with the overarching aim of keeping the soil healthy enough to meet the yield requirements of a growing population whilst trying to avoid polluting water and excessive carbon loss.

The process of making this boardgame involved brainstorming sessions to form a game design and rigorous research to make sure our concepts were backed by up-to-date science, play testing with other soil scientists and a variety of other communities to make sure both the mechanics and science worked, and lastly making it look appealing by engaging with a graphic designer. As of today, Dirty Matters is free to download and printer friendly educational tool to advance the understanding of soil and how we should take care of it and everything in it.

#### PERCEPTION OF LOCAL PEOPLE ON LAND USE PRACTICES IN THE SOUTHERN ISSYK-KUL REGION, KYRGYZSTAN

G JALILOVA, R OROZAKUNOVA, E BAIBAGYSHEV, N KARABAEV, U BAATAR

Kyrgyz National Agrarian University named after K.I. Skryabin, KYRGYZSTAN

Agriculture is a crucial sector for the livelihood of people in Kyrgyzstan. In this context, the local people perception of agricultural practices plays a significant role in land use management. This study aimed to assess the understanding of land use practices among local residents in four districts of Southern Issyk-Kol in 2020. The research was conducted between June and October 2020 with randomly selected farmers (n=40).

The results revealed that farmers were well aware of the existing challenges and their contribution to decreased agricultural productivity and increased vulnerability to environmental changes. Addressing these challenges requires collaborative efforts from government institutions to empower farmers with the necessary information and resources to adapt to climate-smart agricultural practices. The presence of an agricultural specialist within the Local Self-Government can contribute to a significant positive change in the livelihoods of rural farmers. This recommendation strongly emerges from the findings of this research.

#### SOIL EROSION ON THE VOLCANIC ISLAND OF MONTSERRAT

C. STEVENS, H. TUFFEN, J. QUINTON, P. HAYGARTH

Lancaster University, Lancaster, UNITED KINGDOM

Coral reefs to the west of the island of Montserrat, in the Caribbean, are being swamped by sediment but the source of this sediment has not been identified. The variable topography of the island results in a large number of very small catchments. Associated with these are steep, often deeply incised, ephemeral watercourses called ghauts. After high rainfall some ghauts are associated with flooding transporting sediment to the ocean. We collected 200 sediment samples from 40 ghauts extending from Little Bay in the north of Montserrat, to Plymouth in the south. Samples were transported to Lancaster University and analysed by laser diffraction to determine the particle size distribution. Across the island a majority of the sediments were sand. Whilst on the island we observed that other sources of sediment were likely to be coastal erosion and erosion of volcanic deposits. The volcano on Montserrat became active in 1995 and in the years that followed enormous amounts of volcanic debris were deposited. These deposits are eroding and lead to the transport of large amounts of sediment to the coastal waters. Identifying the relative importance of these sources is a priority for future research.

#### IMPACT OF VEGETATION RESTORATION ON CHANGES OF RUNOFF/SEDIMENT AND UNDERLYING MECHANISM ON LOESS PLATEAU

X. ZHANG, Y. LI, R. LI

Institution of Soil and Water Conservation, NWFU; CAS/MWR, Yangling, Shaanxi, Yangling, CHINA

To improve the ecological environment, China issued a policy of GFG in 1999. Afforestation and revegetation play a prominent role in improving soil properties and controlling soil erosion. A typical catchment was selected to analyze the trends in climate, LUCC, and runoff/sediment from 1960 to 2020, and investigated the role of vegetation restoration in the changes of runoff/sediment in these land-surface processes and the underlying mechanism.

1) Annual precipitation in the area showed a slight decreasing trend over the past 60 years. Landsat-image interpretation showed that, compared to 1980, the area of farmland in 2020 decreased by 46.4%, and that of vegetated area increased by 25.6%. While the average annual streamflow decreased significantly from 35mm in the 1960s to 19mm in the 2010s. The average annual sediment yield dropped from 0.99 billion t to 0.10 billion t over the period.

2) Planting trees and grasses since 1999, significantly affected soil properties. It increased the organic matter content, decreased the soil bulk density, increased the content of >0.25mm water-stable aggregates, enhanced the stability of aggregates, increased the soil porosity, and improved the soil infiltration performance. The structural equation model indicated that soil bulk density, total porosity, and macroaggregate content are the key soil parameters affecting the saturated soil hydraulic conductivity.

3) Budyko's elasticity-coefficient method and fractal theory approach tested that, large-scale ecological restoration since 1999, contributed 66.3% and 81.7% to the change of runoff and sediment yield in the area, respectively. SWAT and the Geodetector tool were further used, and find that the explanatory power for the spatial distribution of runoff, is significantly greater for soil properties such as saturated hydraulic conductivity, organic matter, and total porosity, than for surface human activities like increased vegetation cover and climate factors like precipitation changes.

These findings reveal and corroborate that vegetation restoration affects runoff-sediment changes, in essence by improving soil quality and enhancing water storage and retention capacity.

#### COMPARATIVE ANALYSIS OF LONG-TERM MINERAL FERTILIZER IMPACT ON GROUNDWATER NUTRIENTS IN AN OIL PALM PLANTATION AND A DRAINED SECONDARY FOREST ON TROPICAL PEATLAND

F.U. ANGGAT<sup>1</sup>, S.F. LIM<sup>1</sup>, Y.S. MAH<sup>2</sup>, N.A. BUSMAN<sup>4</sup>, N. MAIE<sup>5</sup>, F.E. SANGOK<sup>3</sup>, L. MELLING<sup>3</sup>

<sup>2</sup> Department of Civil Engineering, Faculty of Engineering, Universiti Malaysia Sarawak, Kota Samarahan, MALAYSIA

<sup>3</sup> Sarawak Tropical Peat Research Institute, Kota Samarahan, MALAYSIA

<sup>4</sup> Graduate School of Bioagricultural Sciences, Nagoya University, Furo-cho, Chikusa-ku, JAPAN

<sup>5</sup> School of Veterinary Medicine, Kitasato University, Towada, JAPAN

Nutrients from fertilizers, when not absorbed by trees or attached to soil particles, can dissolve and be lost through surface run-off, denitrification, and leaching processes. These substances accumulate in surface water and subsequently seep into groundwater, contributing to the deterioration of groundwater quality. Particularly in peat soils, which are highly porous, there is a significant risk of leaching losses from applied fertilizers. In oil palm agroecosystems, where high fertilizer inputs are crucial for maintaining yields, there exists a potential environmental threat particularly to clean water sources and aquatic ecosystems if excess nutrients migrate to waterways. Despite this, research into the long-term effects of fertilizer use on groundwater quality, especially in oil palm plantations located on tropical peatlands, remains limited. This study, therefore, aims to examine the long-term effects of fertilizer use on groundwater nutrients in an oil palm plantation (*Elaeis guineensis*) situated in tropical peatland, comparing it with a nearby drained secondary forest in Sibu town, Sarawak, Malaysia. Groundwater samples were collected from installed monitoring wells across 12 blocks of the oil palm plantation (OPP) (Q1-Q12) and the drained secondary forest (DSF) between January 2011 and December 2017. Sampling resumed from October 2021 to March 2022 following the planting of second-generation oil palms. The results showed that long-term fertilizer application led to increased groundwater acidity in the OPP, particularly after the replanting of second-generation palms, compared to the DSF. Moreover, the concentrations of potassium (K<sup>+</sup>) and chloride (Cl<sup>-</sup>) in groundwater were consistently higher in the OPP than in the DSF throughout both wet and dry seasons, likely due to the leaching of these elements from soil into groundwater post-fertilization. This study is the first to evaluate and provide baseline data on the long-term impact of mineral fertilizer use on groundwater nutrients, aiming to contribute to the conservation of groundwater quality and sustainability of oil palm cultivation in tropical peatlands.

#### GULLY EROSION STUDY IN CHINA

F. ZHENG

Northwest A & F University, YANGLING, SHAANXI, CHINA, CHINA

Gully erosion plays an important role in sediment yield and pollutant transportation within watershed. However, compared with interrill and rill studies, there are limited data available regarding quantification of gully erosion processes, which has restricted the development of process-based erosion model and implementation of conservation measures. Thus, the objective of this study was to quantify erosion processes of ephemeral gully (EG) and classical gully (CG) by using integrated monitoring methods of field observation, simulated experiments, GPS-RTK, 3D Laser Scanner (LiDAR) and geometrical measurement. Moreover, EG erosion processes were quantified and impacts of rainfall, upslope and inflow rates, topography and plough activity on EG erosion were analyzed. Meanwhile, the evolution processes of CG were quantitatively described, and a gully erosion evolution model with high estimated accuracy was developed. In addition, key research points in near future were proposed, including continuous sediment transport equation in watershed needs to be developed; seepage and soil pipe flow impacts on gully erosion processes needs to be quantified; soil erosion prediction models, which can be used to predicts gully erosion, needs to be developed. In conclusion, this study provides an important reference for controlling watershed erosion and developing process-based erosion model.

#### NITROGEN LEGACY AND ITS IMPACT ON MANAGEMENT IN THE CHANGJIANG RIVER BASIN

C. TI

Institute of Soil Science, Chinese Academy of Sciences, Nanjing, CHINA

#### NITROGEN LEGACY AND ITS IMPACT ON MANAGEMENT IN THE CHANGJIANG RIVER BASIN

Chaopu Ti, Xinliang Wang, Shuang gao

State Key Laboratory of Soil and Sustainable Agriculture, Changshu National Agro-Ecosystem Observation and Research Station, Institute of Soil Science, Chinese Academy of Sciences, Nanjing, 210008, China

Legacy effects induced by soil nitrogen (N) biogeochemical transformation and hydrological could impact on the achievement of water quality goals. It is explicit that the N legacy effect is crucial for improving soil and water quality and enhancing ecological environmental quality. Despite the improvement in environmental protection strategies over the past 20 years, especially since Chairman Xi proposed Green mountains and clear waters are as valuable as mountains of gold and silver in 2005, Significant progress has been made in water pollution control in China, but in recent years, some basins still face pollution issues.

Here, we utilized a modified Soil Water Assessment Tool (SWAT) coupled with a groundwater travel time distribution module to capture the effects of N legacies on N export from the Changjiang River Basin. The results show that the improved model is highly applicable to the Changjiang River Basin. Through model simulations, there is an increasing trend in N output in this Basin, with N output nearly tripling over the past half-century.

We found that different N reduction scenarios lead to a decrease in N output at the estuary. However, there is a significant time lag between input reduction and subsequent reduction in basin output N among different nitrogen reduction schemes. In other words, achieving the same N export reduction requires more time for a 30% N reduction compared to a 50% nitrogen reduction. In summary, under different N management scenarios, both the reduction rate of basin N output and the time required to achieve N load reduction are affected. It can be understood that more stringent N reduction measures can achieve water quality benefits more quickly.

#### SOIL PROTECTION IN POLAND – ADVANTAGES AND DISADVANTAGES

E. KACPRZAK<sup>1</sup>, M. SZCZEPANSKA<sup>1</sup>, B. MACKIEWICZ<sup>1</sup>, K. LEWINSKA<sup>2</sup>, J. MORAWSKA<sup>1</sup>, C. KAZMIEROWSKI<sup>2</sup>

<sup>2</sup> Faculty of Geographical and Geological Sciences, Poznan

Soil protection is crucial in the context of the European Green Deal, the UN Sustainable Development Goals and the EU mission 'Caring for Soil is Caring for Life'. The LOESS project is a European soil health restoration program. It focuses on increasing soil knowledge through the development of educational offerings and continuing training programs. Soil protection is an important issue. Based on a review of applicable regulations in this area, it was found that in Poland soil protection is influenced primarily by two legal acts: the Environmental Protection Law Act (Journal of Laws of 2024, item 54) and the Act on the Protection of Agricultural and Forest Land (Journal of Laws 1995, No. 16, item 78). They were modified many times, which did not contribute to optimal soil management. The acts do not have a direct connection with the formal process of education about soils, although the Environmental Protection Act takes into account aspects of broadly understood ecological education. These documents force part of the society (e.g. farmers, officials, investors) to acquire knowledge about soil, e.g. in terms of soil quality, soil types, erosion threats, protection and reclamation rules. Thus, they commit to soil protection and rational land management. Soil protection takes into account its quality. The legislation limits the use of agricultural land for non-agricultural purposes, protecting the best quality land. Nevertheless, scientific research indicates that agricultural land of good quality is also excluded from agricultural use. This is a disturbing phenomenon because the quality of Polish soil is among the lowest in Europe - 1/3 of arable land is poor and very poor. Therefore, first of all, high-quality soils should be protected. It should also be emphasized that in Poland the protection of agricultural land in cities has been abandoned, which has a particularly negative impact on the functioning and development of urban agriculture.

Research co-financed by the EU, Project LOESS 101112707 HORIZON-MISS-2022-SOIL-01

<sup>3</sup> Department of Soil, Plant, and Food Sciences, University of Bari Aldo Moro, Via Amendola 165/A, 70126 Bari, Italy, Bari, ITALY

The environment is contaminated with numerous substances that are hazardous to human and environment health. Particularly, water pollution is of great concern as water resources are the basis of life and all human activities. Among the contaminants detected in surface- and ground-water there are organic pollutants such as pharmaceuticals and dyes. To date, many methods such as biodegradation, membrane filtration, sedimentation and advanced oxidation processes have been widely used to remove pollutants from water. Adsorption is very attractive in view of its simplicity of implementation, cost-effectiveness and no by-product formation. Several materials have been proposed as adsorbents; among them, magnetic materials have caused high attention because they can be easily and rapidly separated from the aqueous solution; in fact, no centrifugation or filtration is required but only the application of an external magnetic field. Experiments were conducted to evaluate the capacity of two magnetic chitosan-based materials to remove the organic contaminants. In a first study, aqueous solutions containing methylene blue (MB) were treated with a magnetic chitosan-based nanocomposite, obtained by cross-linking chitosan on the surface of magnetic nanoparticles of iron oxides using glutaraldehyde as cross-linking agent. In a second study a magnetic chitosan-based nanocomposite, synthesized through a co-precipitation of chitosan, ferrous sulphate heptahydrate and ferric chloride hexahydrate, was used for the removal of sulfamethoxazole (SMX) from aqueous solutions. In both cases, the effect of pH, treatment time, adsorbent dosage and initial pollutant concentration on the absorption capacity were studied. Moreover, the ability of the above materials to be regenerated and reused was assessed by running consecutive adsorption/desorption cycles. The highest adsorption capacity of MB was 150000 mg/kg at pH 4.0, while the highest adsorption capacity of SMX was 264300 micromol/kg at pH 7.0. These results are encouraging, showing that adsorption on magnetic chitosan-based materials is an effective and low-cost method for the decontamination of waters.

#### DYNAMICS OF WATER-SOLUBLE METALS IN SOIL MOISTENED WITH CITRUS WASTEWATERS DEPENDS ON SOIL REACTION AND ORGANIC ACIDS

D. PAMPINELLA, L. BADALUCCO, A. IOPPOLO, E. PALAZZOLO, F. SAIANO, V.A. LAUDICINA

University of Palermo, Department of Agriculture, Food and Forest Sciences, Palermo, ITALIA

The demand of water for civil and industrial use is diminishing the availability of such a valuable environmental resource for agricultural purposes. Thus, for the next generation it is imperative to find alternative water source for crop irrigation. Wastewaters produced by citrus industry (CWWs) are rich of organic matter and mineral nutrients thus making them potentially usable for crop irrigation. Conversely, due to their high content of organic acids and low pH, they may increase the availability of soluble metals, both plant nutrient and contaminants.

The aim of this study was to evaluate the effect of CWWs on the dynamics of soil water-soluble metals and pH. To this end, CWWs coming from the processing of lemons, oranges, and tangerines, at three different doses, were used. CWWs were analyzed to investigate type and amount of organic acids. Soil water-soluble metals (Na, Mg, Al, K, Ca, Fe, Co, Ni, Cu, Zn, Cd) and pH were determined at day 1, 3, 7, 21 and 28 since the addition of CWWs. After the addition of CWWs, soil pH promptly decreased from 7.2 to, at least, 5.3 depending on the type and concentration of CWWs.

Concurrently, the concentration of almost all investigated metals sharply increased within 7 days after the addition of CWWs. Then, it decreased reaching values similar to that of the control.

The increase of metals availability as a consequence of pH decrease was ascribed to different causes: exchange reaction between H<sup>+</sup> and cations adsorbed onto colloids surface, addition of organic matter by CWWs that stimulated microbial activity and quantity and type of organic acids added via CWWs.

In conclusion, obtained results suggest that the use of citrus wastewater for irrigation purposes could be a valid solution being them rich in plant nutrients and easily mobilizes macro-nutrients.

Further research is needed to enhance the understanding of the long-term impact of CWWs and to develop targeted strategies for managing industrial wastewater in agriculture.

#### CAN AGROFORESTRY CONSERVE THE SOIL AND SECURE LIVELIHOODS IN HIGHLY ERODED SLOPES IN THE PHILIPPINES?

G.S. BHULLAR<sup>1</sup>, A. GARCIA<sup>2</sup>

<sup>1</sup> BFH-HAFL, Zollikofen, SWITZERLAND

<sup>2</sup> University of Southern Mindanao, Carmen, PHILIPPINES

This work presents a field study conducted in the North Cotabato region of the Philippines. The Cotabato Province, renowned for being the food basket of the Philippines, paradoxically also has one of the highest poverty and food insecurity rates. Decades of conflict afflicting the region has led to farmers deprived of know-how and resources to sustainably enhance their productivity and uplift their livelihoods. Adoption of poorly informed farming practices has led to degradation of natural resources, most importantly soil and water. The intensive monoculture of maize (corn) on deforested hilly slopes using practices similar to flat lands is a major matter of concern.

This is probably the first study evaluating and documenting the impact of different farming practices on soil and water in the region, which is of crucial value for policy institutions. This study was conducted in eight barangays (villages) of the Carmen municipality, namely, Macabenban, Liliongan, Cadiis, Aroman, Bentangan, Macabenban, Tambad, Kibudtungan. At each location two field sites close to each other with comparable soil conditions were selected respectively under corn and banana production. The field sites were spread across a range of different slope gradients and being in hilly area, most of them (except 3) had more than 30% slope. We found that, irrespective of the crop grown, the soil cover is most important factor in reducing soil erosion. An exposed field i.e. without any green cover may lose more than 75 tons of soil per hectare per year, taking along the fertility of the field. Along with the ploughing during / just before rains, the application of non-selective herbicides was a strong contributor to soil erosion.

### BRONZE AGE ANTHROSOLS, TECHNOSOL, OR 'JUST' CULTURAL LAYERS? UNDERSTANDING THE DIRT WE DIG IN NORTH ITALIAN ARCHAEOLOGICAL SITES

C. NICOSIA<sup>1</sup>, F. POLISCA<sup>1</sup>, M. BALDAN<sup>1</sup>, D. BATTISTEL<sup>2</sup>, M. BORTOLINI<sup>2</sup>, M. CUPITÒ<sup>3</sup>, M. DAL CORSO<sup>1</sup>

<sup>2</sup> Department of Environmental Sciences, Informatics and Statistics, Cà Foscari University of Venice, Venice, ITALY

<sup>3</sup> Dipartimento dei Beni Culturali, Università di Padova, Padova, ITALY

In northern Italy, especially since the Middle Bronze Age (MBA, 1650-1300 cal BCE) we see the widespread colonization of the floodplain by large embanked settlements, known as Terramara. At the same time, deforestation, hydraulic systems (moats, wells, irrigation ditches), earthen structures and roads requiring enormous quantities of soil material, reveal the intensification of human impact on the soilscape. Yet, very little is known about the soils that were the core of this advanced agricultural system. Only within settlements some witnesses of such soils have so far been encountered. These are often agricultural or horticultural topsoil horizons (Anthrosols) formed on an archaeological parent material, normally referred to as 'cultural layers'. These cultural layers can also be undisturbed, i.e. when their accretion rate is very fast or when they are fast buried, and therefore lack any pedogenic trait. Conversely, when accretion is gradual and exposure prolonged, cultural layers can be affected by soil forming-processes such as leaching and bioturbation, giving rise to weakly developed Technosols. In all these three different scenarios, these soils represent a source of archaeological information on human dwelling and on agricultural practices taking place within the sites. Some of these archaeological soils were therefore studied using pedological, archaeobotanical, and geochemical methods (i.e. the GC-MS analysis of soil organic fraction). The study addressed various Terramara sites of the Veneto region of NE Italy that cover the timespan between the Middle, Late (LBA), and Final Bronze Age (FBA). These include La Muraiola di Povegliano (MBA-LBA), Fondo Paviani (MBA-early FBA), Castelar di Leppia (LBA-FBA), Frattesina, and Villamarzana (FBA-Early Iron Age).

### PALEOENVIRONMENTAL STUDIES AT MIDDLE BRONZE AGE ERIMI IN CYPRUS

I. RELLINI <sup>1</sup>, S. GHISLANDI <sup>1</sup>, P. NIYOKWIRINGIRWA <sup>1</sup>, M.L. AMADIO <sup>3</sup>, L. BOMBARDIERI <sup>2</sup>

<sup>1</sup> University of Genoa, Department of Earth Environment and Life Science (DISTAV), Genoa, ITALY

<sup>2</sup> University of Siena, Department of Philology and Criticism of ancient and modern literatures (DFCLAM), Siena, ITALY

<sup>3</sup> Ghent University, Department of Archeology, Ghent, BELGIUM

This paper focuses on the first pedo-stratigraphic research performed in the landscape of the Kouris river Valley, in the south region of Cyprus. This represents an area of intensive human occupation from the early Neolithic period. The study proposed is part of the PRIN project "EARTHERITAGE, Earthen Heritage in the Eastern Mediterranean between Archaeology and Sustainability", conducted by the joint team of the Universities of Genova, Siena and Palermo. The project has received funding from the Italian Ministry of Education, University and Research (MIUR) under grant agreement N. 2022H3K7W9.

The study presented constitutes the first stage of a two-year programme finalised at fostering the current state of the art about earthen architecture in the Mediterranean region focusing on the island of Cyprus. In particular, the research aims at reconstructing the paleoenvironmental changes of Kouris Valley from the Pleistocene to historic time and the related human-environment interactions, using GIS approach with conventional soil and geomorphological survey.

The spatial distribution and variability of the most extensive soil types were analysed and several stratigraphic sequences with buried paleosols were described in natural exposures. The age of paleosol was estimated on the base of artefacts and on a few radiocarbon analyses. Soil chronosequences and catenas provided stratigraphic control allowing the correlation among different landforms. Soil micromorphology was used in conjunction with routine laboratory analyses in order to determine their genesis and to assess their palaeoclimatic significance. The research consented to greatly expand the environmental data available for the southern region of Cyprus.

Finally, statistical analysis of the spatial relationships between archaeological record locations and landform units permitted us to determine whether there was a significant correlation between Erimi site location and specific geomorphic elements.

### CHARACTERIZATION OF ANTICS STREETS AND ROADS IMPROVEMENTS THROUGH GEOARCHAEOLOGY FROM THE PREVENTIVE ARCHEOLOGY DATA IN THE NORTHEAST OF FRANCE

M. CHARBONNIER<sup>1</sup>, M. CAMMAS<sup>2</sup>

<sup>1</sup> Inrap, Paris, FRANCE

<sup>2</sup> Inrap, paris, FRANCE

<sup>3</sup> aoroc, paris, FRANCE

<sup>4</sup> ASM, montpellier, FRANCE

Over the last few decades, the development of preventive archaeology and research into traffic routes have led to significant advances in our knowledge of the road network and ancient urban structures in France.

Recently, as part of preventive operations, the use of other methods, such as micromorphology, has been envisaged in the case of streets and lanes identified during the field phase. Geoarchaeology makes it possible, on the one hand, to study the materiality of a traffic area on a large scale - through the organisation and hierarchisation of the elements making up the road networks using a detailed stratigraphic study and micromorphological analyses - and, on the other hand, to document the ways in which these areas were laid out and functioned - trampling and driving - and how they changed over time.

The results of the micromorphological analyses reveal specific soil and sedimentary characteristics and highlight significant microstratigraphic variations in the socio-spatial uses of these traffic routes. These analyses provide answers to archaeological questions about the passage, spatial organisation and function of these areas (developed and undeveloped spaces).

This recent research has broadened our perception of streets, roads and paths. They show that they should not be considered as a massive deposit or a superimposition of backfill, but should be studied using the same geoarchaeological tools as other archaeological deposits. As a result, the various micromorphological studies carried out as part of preventive archaeology operations enable us to move away from the view of a road or street as a simple paved area and shed new light on traffic roads (Charbonnier, Cammas 2018).

<sup>3</sup> Soprintendenza Archeologia Belle Arti e Paesaggio (Viterbo ed Etruria meridionale), Ministry of Cultural Heritage, Roma, ITALY

Wooden pile dwellings (WPD) inform on landscape evolution and cultural activities developed around lakes. Much research has been performed on WPD submerged in Alpine areas, however, knowledge is missing from Mediterranean volcanic lakes. Furthermore, the conservation of these archaeological remnants is threatened by the ongoing climatic changes and anthropogenic pressures which are more intense in small and sensitive lake environments.

The study of WPD in Mediterranean lakes was the object of WOODPDLAKE project financed by JPI-CH19. Its main objective was to assess the impact of extreme climate events and anthropic pressure on the conservation and safeguard of pile dwellings in Mediterranean lakes. The research was interdisciplinary merging environmental analyses (water and sediment quality) with the investigation carried out on WPD through dendrochronology, wood degradation analysis based on physical, chemical and morphological analyses. Furthermore, an artificial ageing experiment, performed in aquarium using sediments and samples of waterlogged wood collected from Bolsena lake, allowed to estimate the effect of induced climatic stress (namely high temperature) on wood degradation.

The conservation of waterlogged archaeological wood (WAW) is strongly dependent on the environmental context surrounding it, in particular sediments and water. These, together with the primary intrinsic physico-chemical properties of wood, are two natural matrices affecting each other, with an impact on the intensity of deterioration/conservation rates.

The physico-chemical (texture, total organic C and N, inorganic N and P, redox potential, pH, total elements and heavy metals), biochemical (enzymatic activities belonging to C, N, P and S cycling) and microbiological (EL-FAME profiles) properties of Gran Carro archaeological site sediments were assessed during the three years of the project (2021-2023). The aims of the study were to: i) characterise the environmental context surrounding WAW, ii) demonstrate a likely "wood effect", if any, due to the presence of WAW.

#### INSIGHTS INTO THE CONCEPT OF SOILS AS SUBJECTS OF LAW

H. BERNAL <sup>1</sup>, O. UNAMUNZAGA <sup>2</sup>, I. ALKORTA <sup>1</sup>, C. GARBISU <sup>2</sup>

<sup>1</sup> University of the Basque Country, Leioa, SPAIN

<sup>2</sup> NEIKER-Basque Institute for Agricultural Research and Development, Derio, SPAIN

The survival of our society is inextricably linked to the integrity of the soil ecosystem. In fact, healthy soils are the basis of all terrestrial life and ecosystems. Regrettably, the extent of soil degradation worldwide is a matter of much concern. In the light of such degradation and its consequences for our society, more and more voices are being raised to call for the recognition of soils as subjects of law. This notion is not new, the UN General Assembly on Harmony with Nature has highlighted the inherent rights of nature, a concept supported on the recognition that humankind and nature share a vital, non-anthropocentric relationship. Nature's rights are formulated as recognized, as opposed to granted by humans, and as such, our role is to use legal mechanisms to enforce the rights of species and ecosystems to exist, flourish and be restored. The declaration of nature's components as subjects of law is a consequence of a shift in our relationship with nature, from exploitation to protection and respect. Soils have attracted a low degree of interest from an emotional point of view and, concomitantly, conservation perspective. This circumstance is reflected in the initiatives on nature's rights which have ignored the world's soils. But hopeful changes are perceived, as reflected in the fact that the Center for Democratic and Environmental Rights launched a "Land That Owns Itself Program" and, in 2022, released "A Rights of Soil Model Law". Many initiatives worldwide have dealt with the maintenance and recovery of soil health. But soils are dynamic, evolving ecosystems of overwhelming complexity, whose functioning is supported, on the activity and biodiversity of a myriad of biological species whose roles, interactions and patterns of response are largely unknown. There is still debate on key aspects of soil health monitoring, which hinders the use of the soil health concept as the foundation of the proposal of soil as a subject of law.

**SOIL SONICS, FLYING ROOTS AND THE EARTHWORM AMBULANCE: CURATORIAL PRACTICES AND RELATIONAL MATERIALITY OF SOILS IN THE DANISH EXHIBITION PLATFORM RENÆSSANCEJORD.**

E.M. LUND MALIK

Institute for cultural studies and oriental language, Faculty of Humanities, University of Oslo, Oslo, NORWAY  
Vitenparken Science Center, Ås, NORWAY

There is a growing scene of art and science constellations facing the global soil crisis with soil exhibitions (Toland). Curated by the Danish Jordens Hus (House of Soil), the exhibition series called Renæssancejord consists of six exhibitions in 2023-2024 taking place in a former prison outside of Copenhagen. As Renæssancejord unfolds, artists, architects, designers and scientists carry their own weight in soil, identify with soil living creatures, craft soil sound recordings into sculptures and make earthworm ambulance.

In the article "Towards a Relational Materiality of Soils", Anna Krzywoszynska and Greta Marchesi pose the question of what modes of co-being emerge as we follow soil entities and soil processes, with the aid of art-enhanced apparatuses? Expanding this notion into the context of sensory museology (Howes) and curatorial studies (Von Bismarck), I explore what soil realities that get enacted in the exhibition platform Renæssancejord and the different artistic ways of making sense of soil matters. Visiting these diverse exhibitions, I contemplate "the curatorial" of these exhibitions attentively, focusing on the sensorial and affective encounters it stages between soils and visitors. How does the curatorial perform different materialities and scalar complexities of soils?

The exhibition series is not only legitimized through aesthetics and as reinforcement of soil connectivity (Pino et al.), but art is also a proclaimed catalyst in a collaboration project with the city development program Vridsløselille. Renæssancejord is played out to give new life in the citadel of Albertslund, create social meetings and cultural communities. As Renæssancejord unravels, the curatorial practices around artisanal soil transform the former prison into a public place, and in reverse, the prison surroundings impacts the curatorial.

<sup>3</sup> Colegio de Posgraduados en Ciencias Agrícolas, TEXCOCO, MÉXICO

<sup>4</sup> Escuela de Trabajo Social, Universidad Nacional Autónoma de México, Ciudad de México, MÉXICO

The construction of the Regional Soil Museum was based on the approaches of Environmental Education, because it provides tools to generate a link between the understanding of soil processes, the environment and the social actors involved in the use and conservation of pine and oak forests. It exhibits a collection of ten soil monoliths of the Entisol Order with contrasting characteristics, described and classified in local and scientific terms. The methodology for the collection and exhibition of the specimens is based on the work of Dr. Carlos A. Ortiz Solorio, Dr. Ma. Carmen Gutiérrez Castorena and M. C. Patricio Sánchez Guzmán, from the Genesis, Morphology and Soil Classification Area, Soil Science Program, Colegio de Postgraduados en Ciencias Agrícolas, in Mexico; The installation of the resiento was made possible by the support of local authorities, community members and the general population of the municipality of San Miguel Peras, Zaachila, Oaxaca, owners of a vast territory where nature and society have evolved together throughout history as a wide biological and cultural diversity. The Museum offers the observer the attributes of the soil in unaltered conditions and exposes the role they play in the environmental dynamics of the regional forests and agroecosystems; offers biannual training courses and workshops for sustainable land management. The design and construction of the Regional Soil Museum fosters the values and practical skills to participate responsibly in the solution of environmental problems and the management of the territory.

#### AN ASSESSMENT OF COLONIAL AND POST-INDEPENDENCE SOIL SCIENCE IN ZAMBIA

L.M. CHABALA<sup>1</sup>, C. MITI<sup>2</sup>, I. MUKUMBUTA<sup>3</sup>, S. SICHINGA<sup>4</sup>, R.M. LARK<sup>2</sup>

<sup>1</sup> University of Zambia, Lusaka, ZAMBIA

<sup>2</sup> University of Nottingham,, UNITED KINGDOM

<sup>3</sup> Golden Valley Agricultural Research Trust, Lusaka, ZAMBIA

<sup>4</sup> Zambia Agriculture Research Institute, Lusaka, ZAMBIA

The role soils play in optimizing food production and providing ecosystem functions necessitates a transdisciplinary appraisal of its study in Africa and the world over. We undertook a comparative assessment of the Exploratory Soil Map of Zambia (ESMZ) produced in 1991 and the Vegetation–Soil Map produced by Trapnell and colleagues in 1947. We examined differences between broad soil physiographic units of the two maps. We examined a number of exemplar transects undertaken by Trapnell from 1932 to 1942, evaluating the information provided on soil, vegetation, landscape, and farming systems. A comparison of the legend units of the ESMZ (1991) and Trapnell's 1947 map was done. A reading protocol was developed which was used to examine the records and extract information on soils, vegetation, and farming systems. For a subset of the large-scale post -independence map-sheets, we compared the texture and intricacy of the mapped boundaries with international standards based on average size delineation (ASD) and index of maximum reduction (IMR). Results showed that there was no significant variation in the soil properties with clear similarities observed between the soil physiographic units of the Trapnell's Soil–Vegetation Map of 1947 and broader physiographic units into which the legend units of the ESMZ of 1991 are grouped. It was noted that detailed information about farming practices can be used to understand how these have changed over time. Our assessment of a subset of post-independence map sheets showed that the map scale was consistent with the index of maximum reduction (IMR) and appropriate for the declared use of the survey. However, the publication scale and the texture/complexity of the surveys were not entirely consistent with international norms. This does not necessarily reflect poorly on past surveys but reflects, in part, the intricacy of the local soil landscape. We therefore, concluded that legacy soil records remain a valuable resource in understanding current land management issues and can help track changes overtime.

#### FROM “NATIONAL WEALTH” TO “HUMAN HEALTH”: DISCOURSES OF SOIL CONSERVATION AND SOIL HEALTH DURING THE SECOND AMERICAN AGRICULTURAL REVOLUTION

K. LAWLESS

Huron University, LONDON, CANADA

This paper explores the emergence of the soil conservation and soil health concepts during the second American agricultural revolution. I argue that the concepts of soil health and conservation are not only related, but also complementary, and reflected deep anxieties about the stability of the nation-state in a time of massive social upheaval. While the soil conservation concept preceded the soil health concept by several decades in soil science, they emerged simultaneously in the political sphere. Despite its association with the Dust Bowl of the 1930s, soil conservation emerged much earlier, in the mid-nineteenth century, among New England farmers who recognized the impacts of their practice in the changing colour of their soils. It didn't appear in soil scientific literature until the late 1920s but made its official debut in soil conservation “crusader” H.H. Bennett's work in the 1930s. The soil health concept has a similar story. While it didn't appear in soil scientific literature until the 1950s and didn't enjoy widespread visibility until quite recently, soil health was the brainchild of farmers in the early 20th century, including Henry Wallace. This is where these stories converge. Both Bennett and Wallace, in their own ways, recognized a connection between the poverty of a soil and the poverty of a people. Bennett, for example, expresses the “evils” of soil erosion in terms like “wasteful” and “costly,” and he attributed these to the “immigrants,” the “colonialists.” Hence, soil conservation sought to conserve what remained. Soil health, by contrast, sought to restore soils that had been depleted, returning and growing productivity. Equally importantly, they signalled a shift in discourses through the second half of the American agricultural revolution. Indeed, if soil conservation expressed anxieties about national wealth as imbued in a nation's natural resources, and the costly choice to plunder them, soil health reframed these economics in terms of the service of human health provided by healthy soils.

#### GROUNDING INTERNATIONALISM: THE HISTORY OF INTERNATIONAL SOIL SCIENCE BETWEEN THE WARS

N. UJHÁZY, M. HEFFERNAN

University of Nottingham - School of Geography, Nottingham, UNITED KINGDOM

This paper re-considers the early 20th century history of soil science as an example of scientific internationalism, focusing on the role of the International Institute of Agriculture (IIA), established in Rome in 1905 by the American businessman and agriculturalist David Lubin. The IIA was the co-ordinating organisation in which the International Society of Soil Science (ISSS) operated from 1924 until World War Two. Drawing on the IIA's international networks and alliances, the ISSS sought to foster international scientific cooperation, improve the management of soils in different regions of the world, and secure global food production. However, the political landscape of interwar Europe - in which rival nation-states sought not just to expand cultivation of their underdeveloped territories but also challenge existing state borders - partially undermined the ISSS's internationalist ambitions. The paper examines the complex politics of the ISSS's endeavours in this period, the attempts by nationalist and internationalist agendas to influence the practice of soil science, and the organisation's reconstitution after the war as an independent agency.

**WHAT ROLE FOR SCIENCE IN CONSTITUTING SOIL HEALTH AS A POLICY-PROBLEM? THE EXAMPLE OF SOIL COMPACTION IN GERMANY**

K.M. BAEUMLER<sup>1</sup>, M. SOEDER<sup>2</sup>, B. STEINHOFF-KNOPP<sup>2</sup>, P.H. FEINDT<sup>3</sup>

<sup>1</sup> Thünen Institute (Coordination Unit Climate, Soil, Biodiversity), Humboldt-Universität zu Berlin (Thaer Institute), Braunschweig, Berlin, GERMANY

<sup>2</sup> Thünen Institute (Coordination Unit Climate, Soil, Biodiversity), Braunschweig, GERMANY

<sup>3</sup> Humboldt-Universität zu Berlin, Thaer Institute, Agriculture and Food Policy Group, Berlin, GERMANY

<sup>4</sup> GERMANY

While soil health has become the topic of legislative initiatives, it remains relatively unexplored in critical policy studies. We thus inspect the interface of scientific and political discourses around soil health, taking the example of soil compaction as a subtopic in Germany. Specifically, we analyse the role of scientific knowledge on soil compaction in constituting it as a policy problem.

We follow constructivist researchers by positing that soil compaction is not a strictly objective problem but rather represents social constructions. It is the product of a political process that defines and attaches it to particular political interests. We accordingly investigate the politics of knowledge, namely the “political motivations, political employment and political effects ” (Hurri & Kestilä, 2019, p. 12), of scientific knowledge on soil compaction at the science-policy-interface.

The study revolves around two core analyses: of the scientific community's supply of knowledge and the policy community's demand of knowledge. For the supply dimension we dissect the degree of scientific consensus regarding soil compaction within soil science and agricultural economics. For the demand side we probe how scientific knowledge is reflected in policymaking. We examine the reproduction of scientific positions, the political preference or refusal of certain scientific positions, and the underlying reasons for their acceptance or dismissal. We show whether scientific knowledge is considered a neutral fact that answers political questions, or whether scientific knowledge provides “a source of questions that need to be politically answered” (Dominguez Rubio & Baert, 2022, p. 3).

We conducted semi-structured interviews with experts on soil compaction and key actors in German soil health policy formulation. The data was analysed with qualitative content analysis to systematically identify thematic aspects and conceptualise them.

By scrutinising the interplay between scientific narratives and political actions, our research aims to shed light on the constructed nature of soil health as a policy problem, thereby contributing to the understanding of the politics surrounding soil health issues in Germany.

### FOOTPATHS: A HUMAN-MADE SOIL SURFACE AND ITS POSSIBLE ENVIRONMENTAL IMPACT

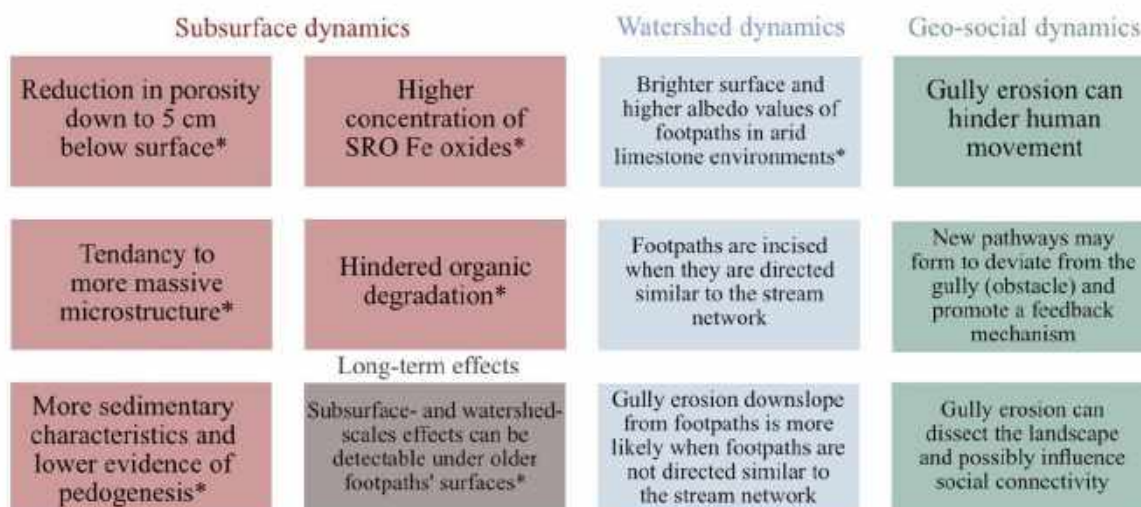

N. NIR<sup>1</sup>, M. STAHLSCHMIDT<sup>2</sup>, M. ULLMAN<sup>3</sup>, U. DAVIDOVICH<sup>3</sup>, B. SCHÜTT<sup>1</sup>, J. HARDT<sup>1</sup>

<sup>1</sup> Physische Geographie, Freie Universität Berlin, BERLIN, GERMANY

<sup>2</sup> Department for Evolutionary Anthropology, University of Vienna, vienna, AUSTRIA

<sup>3</sup> Hebrew University of Jerusalem, Jerusalem, ISRAEL

Footpaths are widely distributed socio-cultural soils and sediments. These forms of human imprint on the landscape, offer a unique window into understanding the intricate relationships between humans and soils. The elongated features are the outcome of continuous human movement over time scales ranging from days to centuries or millennia. In this overview of our recent insights, we adopt a holistic approach that integrates micromorphology (including voids analysis), chemical soil parameters (such as selective iron oxide dissolution), and remote sensing (assessing spatial distribution, orientation of footpaths, and color differences) to assess the enduring residues and environmental impacts resulting from the formation of footpaths. Our diverse case studies explore footpaths utilized for recreational and transport purposes across temperate, sub-humid, and arid climates, considering both recent and archaeological perspectives. Microscopically, the studied footpaths exhibit lower porosity and fewer biogenic activities compared to their non-path counterparts, influencing the sub-surface environment. This lower porosity restricts the supply of oxygen and/or water, fostering water stagnation on the compacted footpath surface. These processes result in elevated levels of pedogenic Fe oxides and, at times, macro-organic residues under footpaths, affecting soil formation. Through field observations and color analysis, we uncover that footpaths in arid limestone environments may lead to a brighter surface color than their non-path surroundings. This color alteration is confirmed through laboratory analysis and high-resolution remote sensing, highlighting significant differences. As an additional consequence of compaction, surface runoff is promoted, potentially triggering the initiation of gullies downslope from footpaths or leading to the incision of footpaths themselves. The likelihood of incised footpaths increases when oriented parallel to the stream network. Once formed, incised footpaths may reduce gully erosion susceptibility downslope, acting as channels that decrease a footpath's 'overbank' flow. This transdisciplinary study invites a collaborative effort for recognizing human impact and supporting sustainable soil management.

**ACTIVITIES CARRIED OUT BY THE SOIL EDUCATION AND PUBLIC AWARENESS SECTION OF THE SPANISH SOCIETY OF SOIL SCIENCE FOR THE KNOWLEDGE OF SOIL BY SCHOOLCHILDREN**

C. LULL <sup>1</sup>, M. SORIANO <sup>2</sup>, C. ORTS <sup>3</sup>

<sup>1</sup> Universitat Politècnica de València. Department of Chemistry, VALENCIA, SPAIN

<sup>2</sup> Universitat Politècnica de València. Departamento de Producción Vegetal. Universitat Politècnica de València, VALENCIA, SPAIN

<sup>3</sup> IVIA. Universitat Politècnica de València. Departamento de Producción Vegetal. Universitat Politècnica de València, VALENCIA, SPAIN

The objective of the Soil Education and Public Awareness Section of the Spanish Society of Soil Science (SECS) is to make known the essential role of soils for life and to raise awareness of the need to ensure their sustainable development, especially among schoolchildren and university students. To protect the soil, it is essential to spread the knowledge of Soil Science. Among the activities carried out were workshops with primary and secondary school children. The experiments carried out were very carefully chosen so that they learn about soils and soil properties according to the age of the schoolchildren. The schoolchildren completed a questionnaire before conducting the experiments and answered a few questions at the end of the workshop. In the workshop, the students determined the texture to the touch, observed the reaction of organic matter with hydrogen peroxide, measured soil basal respiration, observed the flocculation of clays and the cation exchange, and studied the infiltration of nutrient solution in the soil. For the sixth consecutive year, the Section launched a school drawing contest to celebrate the World Soil Day (WSD). This year's contest was entitled 'Water and Soil' and more than 250 schoolchildren participated. On the edafoeduca web page (<http://edafoeduca.es/>) where the drawings were uploaded, schoolteachers had information related to the minimum teachings for Primary Education regarding soil (Royal Decree 157/2022). Among this information was that primary school students need to know how to identify the relationship between people's lives and their actions on environmental elements and resources such as soil and water, and consolidate healthy and sustainable lifestyles, such as those aimed at a responsible management of soil, air, water. The Section participates in the IUSS educational project 'THE IUSS GOES TO THE SCHOOL' preparing educational materials for young people, and in the book contest for children organized by the IUSS and FAO on the WSD.

**SOIL CHARACTERISTICS OF PREINDUSTRIAL LIME-BURNING KILN PLATFORMS IN A CENTRAL EUROPEAN FOREST LANDSCAPE**

T.J. NOVÁK<sup>1</sup>, M. TÁLLAI<sup>1</sup>, Z. SÁNDOR<sup>1</sup>, L. SÜTÖ<sup>2</sup>

<sup>1</sup> University of Debrecen, Institute of Agrochemistry and Soil Science, Debrecen, HUNGARY

<sup>2</sup> Eszterházy Károly Catholic University, Eger, HUNGARY

Lime burning was traditionally an important activity in the Bükk Mountain, Northern Hungary. The most common way of constructing preindustrial lime-kilns was to use larger boulders of non-calcareous rocks in the direct vicinity of limestone outcrops to construct the kiln, where the source material for lime-burning was easy to access with simple collection from the surface without necessity of quarrying and transportation. The lime was burned at the occurrence of rock outcrops, where also wood in sufficient amount was available, preferable along roads facilitating the transport of the produced quicklime.

In this study we examined the soil environment of lime-kiln platforms compared to their surrounding's soil characteristics in low-altitude hilly forest stands. Both bulk and undisturbed soil samples were used to assess the basic soil properties, nutrient content, cation exchange capacity, enzyme activity, and soil active carbon content. Soil color, aggregates, coarse fragments, artefacts, root density, and horizon thicknesses were surveyed in the field.

The lime-burning sites show up anthropogenic characteristics as far they have 10-100 cm thick compacted calcareous technic hard material enriched in charcoal and slag. The platforms represented inhospitable technogenic environment while used, but since their abandonment turned into valuable habitats. They are frequently overlaid by organic rich, base-saturated, calcareous humus layer developed as a result of 300-400 years of post-technogenic soil development. The soils classified as Technosol with Isolatic, Spolic, Thyric, and Ekranic principal, and Ochric, Mollic, Supra-mollic Supra-calcaric, and Endodystric supplementary qualifiers.

Our study confirmed that the abandoned lime-burning kiln's platforms act as separate microhabitats in the dominantly acidic Luvisol environment, which show up eluviated soil characteristics in topsoil. In few cases, the studied Technosols overlay non-calcareous, acidic regolith of schists and shales. With their fertile, base saturated topsoil layer they increase the pedodiversity, and also function as an archive for land use history and serves as valuable parts of cultural heritage.

B. XU, B. LI, Z. CHEN, X. WANG

SINOPEC Dalian Research Institute of Petroleum and Petrochemicals Co., Ltd., Dalian Liaoning 116045, China, Dalian, CHINA

In order to alleviate the ecological and human health risks caused by groundwater pollution, it is necessary to take a series of measures to repair and control the pollution. In-situ chemical oxidation remediation is one of the most widely used techniques in groundwater remediation in recent year. However, in-situ chemical oxidation remediation technology also subject to some limitations, such as the tailing or rebound of pollutants.

In order to improve the stability of pollution remediation and achieve continuous and stable release of oxidants, the environment-friendly bentonite and polylactic acid were used as raw materials to prepare controlled-release persulfate material (CRPM) by granulation and coating method. The antibiotic ciprofloxacin commonly detected in water was used as the target pollutant, the degradation effect of CRPM on ciprofloxacin and the release stability of CRPM were investigated. Meanwhile, the changes in the chemical and thermal stability of the polylactic acid coating layer during the oxidation process were characterized. The main findings of this study are as follows:

The release law of the prepared CRPM conforms to the zero-order kinetics ( $R^2 > 0.96$ ), indicating that the CRPM can release sodium persulfate stably. The release rate of the CRPM can be regulated by changing the ratio of porogen NaCl, the size of CRPM and the number of coating layers, so that the release half-lives of persulfate can be adjusted between 4 and 1613 d, which can meet the needs of different remediation period. The characterization by SEM indicated that porogen NaCl and the number of coating layers could control the release rate. The ciprofloxacin was degraded by  $Fe^{2+}$  activated CRPM, and the removal rate of ciprofloxacin was relatively stable for 5 cycles of oxidation, which indicated that the CRPM can stably release persulfate. In addition, the chemical and thermal stability for the polylactic acid coating layer did not change significantly during the oxidation process, and had fairly good stability.

<sup>5</sup> Czech University of Life Sciences Prague, Faculty of Agrobiolgy, Prague, CZECH REPUBLIC

Constructed Technosols are important in urban hydrology, especially in the functioning of stormwater bioretention cells. The study aimed to relate changes in bioretention cell performance to the structural changes of soils at the microscale by invasive and noninvasive methods. X-ray microtomography was used to investigate Constructed Technosol of the biofilter in terms of structure development, pore-clogging and pore geometry deformations.

Two identical bioretention cells were established in December 2017. The subsurface of the cells is formed by biofilter (Constructed Technosol), sand filter, and a drainage layer. The 30 cm thick biofilter soil mixture is composed of 50% sand, 30% compost, and 20% topsoil. Soil sampling program was initiated in 2018 to visualize and quantify the soil structure and internal pore geometry of samples. Over three years, five batches of undistributed samples were taken. Analyses of pore network morphology were performed on the segmented 3D images of samples.

During the first year, the macroporosity decreased in both BCs due to soil consolidation. Results of the study show that short term consolidation was followed by gradual development of macropore system in biofilter. A significant correlation was found between macroporosity and connection probability, as well as between macroporosity and critical diameter. Pore thickness analysis revealed that the most represented pore fraction during the three years was 80-310  $\mu\text{m}$  in size. The biofilter exhibited optimal conditions for plant growth.

**URBAN SOIL COMPACTION: PRELIMINARY RESULTS FROM THE CITY OF MILAN (ITALY)**

C. DE FEUDIS, C. FERRÉ, R. COMOLLI

Milano-Bicocca University - Department of Earth and Environmental Sciences, Milano, ITALY

We present some preliminary results of a research project aimed at studying soil compaction in public green areas in the city of Milan and its potential effects on soil ecological functionality. To achieve this goal, beside soil compaction assessment, the investigation involves the characterization of chemical and physical soil properties, to determine any relationship with compaction. To evaluate soil functionality, water infiltration capacity and soil biological activity will be examined. This project is part of the research activities of the PNRR – NBFC, spoke 5 (“Urban biodiversity”).

Five categories of green areas were selected: lawns of urban parks inside (i) and outside (ii) the historic centre; lawns (iii) and forests (iv) of peri-urban parks; lawns of small urban green spaces (v).

A total of 60 sampling sites were identified. In each of them, a georeferenced experimental plot (4 x 4 m) was defined, to carry out soil sampling and compaction measurements (bulk density and soil resistance to penetration). Soil was sampled by layers (0–10 cm, 10–20 cm, 20–40 cm). Bulk density (BD) was measured on the first 5 cm of depth. Soil resistance to penetration was measured with a field penetrometer up to a maximum depth of 45 cm. Because soil resistance varies depending on soil moisture, soil water content was also measured.

The first data obtained on soil compaction were analysed to determine if any differences emerged among the green area categories. BD of forest was significantly lower (mean  $\pm$  sd:  $0.91 \pm 0.05$  g\*cm<sup>-3</sup>) and BD in lawns of urban central parks was significantly higher ( $1.15 \pm 0.12$  g\*cm<sup>-3</sup>) than BD of the other green area categories. Penetrometer data confirmed that forest soils were significantly less compacted than the others. In all the green area categories except forest, soil resistance increased with depth reaching a maximum at 10-15 cm and then remaining constant or decreasing slightly; in forest soils the increase with depth is more gradual.

<sup>2</sup> ENEA, CR Casaccia, Rome, ITALY

<sup>3</sup> Serbian Environmental Protection Agency (SEPA), Belgrade, SERBIA

Urban soils are influenced by human activities resulting in a change in soil health that can strongly affect human health, plants, and soil organisms. To identify the anthropogenic influence in urban parks in Rome and Novi Sad, cities different in traffic intensity, industrial activities, population, and geomorphology, in the framework of a scientific collaborative project between Serbia and Italy, supported by MAECI a study on soils, plants, and road dust has been carried out. Determining the total concentrations of some potentially toxic elements (PTEs) (such as Pb, Cu, Zn, and Cd) of the urban soil samples confirmed great differences between the nature of the soil of these two cities, mainly related to the different geological settings. However, despite their lower total metal concentrations, samples from Novi Sad exhibit higher mobility than those measured in Rome urban soils (Monteriali et al., 2017).

To get more comprehensive information about soil pollution, a wider list of PTEs and their possible ecological risk, potential indicators, the pollution index, and potential ecological risk index have been calculated. The focus of this study is on the following 20 potentially toxic elements (PTEs): Mn, Cu, Pb, Zn, As, Ba, Cd, Co, Cr, Cs, Ni, Rb, Sb, Sc, Th, U, Zr, Be, V, Sr.

**MONITORING AND MODELING OF SURFACE TEMPERATURE AT BARE-SOIL AND SEDUM COVERED GREEN ROOF**

D. THI MAI DUNG, M. SNEHOTA

Czech Technical University in Prague - Faculty of Civil Engineering,, Prague, CZECH REPUBLIC

Soil surface temperature is one of the key parameters for prediction of evaporation from bare soil and evapotranspiration from vegetated surfaces in natural and urban environments. There is a wealth of literature on the experimental investigation of the surface temperature of agricultural and natural soils, but the experiments monitoring the surface temperature of urban soils are still relatively sparse. This paper analyses the thermal behaviour of an experimental extensive green roof plot, focusing on surface temperature variations and their correlation with environmental factors. The 1x1 square metre green roof plot was located on the larger green roof in a peri-urban environment. The plot was elevated above the roof and thermally insulated from below. The vegetation was established several years before the experiment with a sedum mat covering the plot. The bare patch of soil used in the green roof experiment represented a site where the vegetation had receded since its establishment. Over a period of thirteen weeks, surface temperatures were monitored using a series of thin stainless steel thermistors on both the bare soil and vegetated parts of a green roof plot. The influence of solar radiation on the surface temperature of the roof was analysed along with the temperature of the substrate below, solar radiation and other environmental factors. The study aimed to identify temperature patterns and perform statistical analysis using a simple heat transfer model. The results suggest that vegetation has a significant cooling effect, particularly in warm weather, but that this effect diminishes during periods of dry substrate. The simple thermal model used in the study fitted the actual temperature measurements reasonably well, although it showed limitations during extreme high temperature conditions. The results contribute to a better understanding of the thermal dynamics of green roofs.

**SOIL MONITORING AFTER A DE-SEALING INTERVENTION IN PORTO DI MARE (MILAN, ITALY)**

G. MASCETTI, C. FERRÉ, R. COMOLLI

University of Milano Bicocca - Department of Earth and Environmental Sciences (UNIMIB-DISAT), Milano, ITALY

Artificial soil sealing is one of the main soil degradation processes in Europe. De-sealing, or depaving, is the process of removing the impermeable cover to expose the underlying soil and restore its correct functionality.

The main goals of our project are (i) to assess the effects of different treatments for restoring unsealed soil and (ii) to evaluate the impacts of using pavement demolition waste (DW) as soil parent material. Here we present the preliminary results from a 5-month soil monitoring following a de-sealing intervention carried out at Porto di Mare, an abandoned site in the south-east of Milan. After defining the plots to be used for the various soil recovery treatments, and describing the soil profiles, the following instruments were installed: i) sensors for soil temperature, water, and oxygen content; ii) lysimeters for measuring water percolation. Sensors were also placed under a layer of concrete in a still-sealed part of the site. A 20 cm thick layer of DW was then spread over the entire unsealed soil surface. Four treatments were carried out approximately four months after the de-sealing intervention. For t1 and t2, two distinct herbaceous mixtures were sown directly on top of the debris layer. For t3 and t4, compost was added to the DW before sowing the same mixtures.

In the unsealed area, the soil water content showed an initial increase and daily oscillations which disappeared after the placement of the debris layer on the soil surface. Concurrently, the daily temperature variations became less noticeable. The sealed sensors recorded a trend and temperature values similar to those observed in the unsealed soil surface covered by the debris layer. The water content, on the other hand, showed a gradual and constant decrease. As for the oxygen content, a gradual increase was observed in the unsealed soil.

### DETERMINATION AND ASSESSMENT OF MERCURY CONCENTRATION IN SOIL AND VEGETATION AFFECTED BY A FORMER CINNABAR MINE

R. BOLUDA HERNÁNDEZ <sup>1</sup>, C. FRANCO-PERNAS <sup>1</sup>, L. ROCA-PÉREZ <sup>1</sup>, O. ANDREU-SÁNCHEZ <sup>1</sup>, E. FERNÁNDEZ-GÓMEZ <sup>1</sup>, J. PRO <sup>2</sup>, J. RODRÍGUEZ-MARTÍN <sup>2</sup>

<sup>1</sup> UNIVERSITY OF VALENCIA, Burjassot, SPAIN

<sup>2</sup> INIA-CSIC, Madrid, SPAIN

Mining activity is one of the most relevant anthropogenic sources of worldwide pollution, affecting soil, water and vegetation alike. Even after the mining activity has ceased, metal concentrations remain alarmingly high, which can affect the surrounding vegetation as well as water bodies near the mine. Cinnabar mining leaves a residue of mercury, a heavy metal that is highly toxic, accumulates in soils, and has a high capacity for bioaccumulation. The study of Hg contamination in the proximities of abandoned cinnabar mines is of great interest because it allows us to evaluate the degree of contamination of these sites and the possible environmental and human health risks. The aims of this study were to determine the Hg content in soils and plants of a former cinnabar mining area in the town of Chóvar (Castelló, E Spain), as well as to evaluate the state of contamination by means of the enrichment factor (EF) and potential ecological risk (ERI) indices. Three areas were selected according to their proximity to the cinnabar mine: Masía Mosquera (14 km from the mine), another area 700 m from the mine, and the mine itself. Soil and leaf samples of the Quercus suber tree species were taken in the three areas; the fundamental properties of the soils were analyzed and the Hg concentration in soils and plants was determined using a Milestone™ tri-cell DMA-80 Hg autoanalyzer. Hg concentration in soils and cork oaks in the mining area was significantly higher than in the other two areas, with similar characteristics, and a significant relationship was observed between some soil properties and Hg concentration, as well as between soils and trees, indicating the existence of Hg uptake. The calculation of EF and ERI indicate the existence of significant contamination and ecological risk in the mining area and adjacent areas, which requires soil contamination monitoring and control measures to avoid loss of ecosystem functions and risk to public health.

### ASSESSING DISTRIBUTION OF HEAVY METALS IN SOILS FROM A FORMER BARITE MINE USING BCR SEQUENTIAL EXTRACTION PROCEDURE

R. BOLUDA HERNÁNDEZ <sup>1</sup>, J.A. WELLS <sup>1</sup>, O. ANDREU-SÁNCHEZ <sup>1</sup>, E. FERNÁNDEZ-GÓMEZ <sup>1</sup>, J.A. RODRÍGUEZ-MARTÍN <sup>2</sup>, J. BECH <sup>3</sup>, L. ROCA-PÉREZ <sup>1</sup>

<sup>1</sup> UNIVERSITY OF VALENCIA, Burjassot, SPAIN

<sup>2</sup> INIA-CSIC, Madrid, SPAIN

<sup>3</sup> UNIVERSITY OF BARCELONA, Barcelona, SPAIN

Mining is considered a significant contributor to environmental contamination. Mining activities associated with barite extraction can lead to heavy metal contamination of nearby soils. The total trace element concentration in soils does not represent the available fraction. Sequential extraction procedures allow determining the available fraction, one of the most widely used is the three-step BCR sequential extraction scheme recommended by the European Community Reference Bureau. In BCR the metals are divided into acid soluble/exchangeable, reducible and oxidizable fractions. The main objective of this study was to determine and evaluate the content of Cd, Co, Cr, Cu, Fe, Mn, Ni, Pb and Zn in different fractions of soils near the Atrevida mine (Tarragona, Spain) using the sequential BCR extraction and EDTA extraction procedure. Soil samples were taken in seven locations around the mining area. The physicochemical properties (pH, electrical conductivity, texture, organic matter) of the topsoil samples (0-15 cm) were analyzed by standard methods, and the concentration of heavy metals (Cd, Co, Cr, Cu, Fe, Mn, Ni, Pb and Zn) was determined in different sequential extraction fractions (H<sub>3</sub>COOH, ClH<sub>4</sub>NO, H<sub>2</sub>O<sub>2</sub>), and EDTA extraction (0.05 mol/L, pH=7) by AAS (Agilent Technologies 200 Series AA). In general, the results showed that for all elements analyzed the residual fraction is the more abundant, in the following order: soluble-exchangeable forms < reducible forms < oxidizable forms < available-EDTA << residual forms; manganese was the most abundant metal in the soluble, exchangeable and assimilable fraction, as iron was the most abundant metal in the residual and oxidizable fraction. These results indicated that the elements have low availability, which is related to the characteristics of the soils, suggesting that the environmental risks will be low. Correlations among soil parameters showed significant inverse relationships between pH and Cr, Cu, Fe and Ni content in the same fractions and EDTA, as well as significant direct relationships between EDTA-extracted elemental content and exchangeable and reducible soluble fractions were observed,

<sup>5</sup> Department of Water Resources, Universidad de Concepción, Concepción, CHILE

The Patagonian Vegas constitute the main forage resource in the Magallanes Region, reaching a biomass production about 10 to 20 times higher than the surrounding sub-Antarctic rangelands. Therefore, they represent main economic axes of the region: sheep farming and lamb production, accounting 56% of the national lamb production. The edaphoclimatic conditions i.e., waterlogged soils till late spring and water restriction in summer force the farmers to the implementation of drainage systems which limits the plant water supply, leading to a decrease in growth rates during summer as the soils dries out. Additionally, the increasing animal stocking rates means that soil has to support higher internal and external stresses leading to deterioration of their structure, erosion and intensifying the negative effect of drainage. The aim of drainage is to increase of the air fraction in the pore system; however, this produce a significant soil settlement due to the high organic matter content of Vega Soils (VS) affecting their ability to store and conduct water and air, since the soil volume and pore continuity are reduced due to soil subsidence. Therefore, the aim of this work is to evaluate the changes in pore functions of the VS with different hydraulic history. For this purpose, VS with different management were sampled: Natural Situation (Peatland from Sphagnum sp.), Drained Natural Situation (Peatland from drained Sphagnum sp.), Vega under Conventional Management, Mineral Drained Vega, Undrained Mineral Fertile Lowland, Vega under Intensive Grazing, Vega under Continuous Grazing, Vega Tilled and Grazed, Vega not Tilled and Continuously Grazed. Undisturbed soil samples (n=5, vol=220 cm<sup>3</sup>) were taken from depths: 5 cm and the last horizon before the glaciolacustrine sediment (~80 cm). Under laboratory conditions, the saturated hydraulic conductivity was measured in water permeameter after 1, 2, 6, 12, 24, 48, 72 hours after the water flow start. Before and after this measurement, air conductivity was determinate. At the end the bulk density was determined as well. Fondecyt 1231934

<sup>3</sup> Research Institute For Fodder Crops, Ltd., Troubsko, CZECH REPUBLIC

The largest complex of floodplain forests in the Czech Republic is situated along the confluence of the rivers Morava and Dyje/Thaya. The studied locality is located in an area close to the Czech-Austrian-Slovakian border. Natural conditions, which affected the natural floodplain ecosystem for a long time, were markedly disturbed by man in the '70s of the 20th century. After extensive water-management measures, both rivers including their local tributaries were channelised and diked. Formerly regularly repeating short-term floods were eliminated and as a result, the groundwater level decreased. However, its important annual dynamics have been preserved. The impaired water balance resulted in the local die-back of mature forest stands of the floodplain forest during a climatic dry spell. Monitoring takes place at the right and left banks of the Dyje river. The right bank of the Dyje river is covered by wetland meadows and the area takes approximately 231.87 ha. It is also an important protected catchment of drinking water for municipalities. Stress factors like land use changes, riverbed regulations, and changes in temperature and humidity conditions directly affect the ecosystem stability. On the other hand, revitalization efforts, transboundary river management, wetland restoration, and integrated planning are undertaken to mitigate the negative effects and groundwater decline. Therefore, continuous monitoring and data set collecting are important, especially with the designation of National Nature Reserve Podyjí. This study aims to track changes in groundwater level, soil hydrophysical properties, and forest vitality during the period of 2019-2023. The results were assessed using z-scores, means, and standard deviations. Monthly evaluations of soil and climatic conditions revealed that irregular rainfall patterns and rising temperatures have a significant impact on the soil's hydrological regime and forest growth. Ongoing monitoring is important for developing projection models that can provide a better understanding of changes in both soil properties and tree growth parameters.

**IMPROVED DRAINAGE CAPACITY WITH ALTERNATIVE DRAINAGE METHODS FOR NORWAY**

J STOLTE, E BLOEM, F BØE

Norwegian Institute of Bioeconomy Research (NIBIO), Aas, NORWAY

Climate change is expected to increase precipitation amount and intensity in northern Europe, particularly during extreme events. This increases the need for drainage measures to prolong the growing season. Approximately 60% of the agricultural area in Norway is artificially drained, with the proportion in cropped land areas even higher. Much of the crop land area is located on marine clay in Eastern and Mid Norway. Here, the soil is completely dependent on systematic drainage to provide good yield. In a survey among farmers in Norway it is found that there was a difference of around 300 kg/ha cereal yield between a bad drained and optimal drained field, and up to 850 kg/ha for newly drained fields compared with the 'before-drain' period. High intensity rainfall events lead to flooding and water-logged conditions, which have negative impacts on yield and operational conditions related to tillage and transport. With the goal of an increased degree of self-sufficiency, and in a changing, wetter climate, drainage conditions must be improved.

A project on drainage efficiency is started in 2019, with the goal to increase knowledge about how drainage of cultivated soil with low water conductivity can be improved, with particular focus on new methods as an alternative to traditional drainage. At a field site, torpedo drainage, slotted drainage and traditional drainage systems were installed. We monitored soil pressure heads and water outflow at each drainage pipe. During a rainfall episode we also measured water content changes with electrical resistivity tomography (ERT) at each drainage for better understanding of the hydrogeological processes. In case of a slowly increase of soil water content, the slotted drainage is effective, but during heavier rainfall events or when the soil is already wet, the torpedo drainage is most effective. For peak events as well, the torpedo drainage system exceeds significantly the traditional system by approx. 21%.

##### SENSITIVITY ANALYSIS OF SOIL COMPACTION AND IRRIGATION PRACTICES ON SOIL SALINIZATION IN SEMI-ARID AGRICULTURAL LANDS

B. DEMIREL, S. MAGHAMI NICK, N.K. COPTY

BOGAZICI UNIVERSITY INSTITUTE OF ENVIRONMENTAL SCIENCES, ISTANBUL, TURKEY

The use of saline groundwater for irrigation can lead to significant salt accumulation in agricultural soils. This in turn can lead to decrease in crop yields threatening food security. This problem is particularly encountered in arid and semi-arid environments and when shallow watertable conditions are present. This study examines the sensitivity analysis of capillary rise, soil compaction and irrigation pattern on the salt dynamics in soils in the presence of a shallow saline water table. Water and solute transport in unsaturated soils was numerically modelled with the Hydrus-1D computer program. Results show that capillary action and evaporation from the soil surface can significantly contribute to the accumulation of salts in the topsoil. Sub-surface soil compaction resulted in a greater capillary rise leading to an increased risk of salt accumulation in topsoil in comparison to uncompacted deep tilled soil. It is shown that properly managed irrigation schemes and tillage practices can help alleviate the problem of soil salinization and sodification. The findings of this study underline the significance of developing effective irrigation practices for sustainable agriculture and enhanced food security, and to help conserve limited fresh water resources in arid and semi-arid regions.

**SPATIAL MODELLING OF HYDRAULIC CONDUCTIVITY AND INFILTRATION RATE FOR THE REASSESSMENT OF AGRICULTURAL RESTRICTIONS IN GROUNDWATER PROTECTION AREAS IN SLOVENIA**

M. GRICNIK<sup>1</sup>, B. VRSCAJ<sup>1,2</sup>

<sup>1</sup> Agricultural institute of Slovenia, Ljubljana, SLOVENIA

<sup>2</sup> Faculty of Environmental Protection, Velenje, SLOVENIA

Slovenia has one of the modest arable land area per capita in Europe. Besides that, a significant part of the best agricultural land in Slovenia is located on sandy soils. Following the Nitrates Directive, the Groundwater Protection Areas (GPAs) were defined and restrictions on agricultural production were set. Unfortunately, soil properties were not consulted at that time so the need to reassess agricultural restrictions in GPAs was identified.

Spatial modelling of hydraulic conductivity was conducted using pedotransfer function for texture soil parameters: fractions of clay and sand since those are omnipresent soil parameters in measured soil profiles. Input data was harmonised to depths of 10 cm in the range from 0 to 60 cm to cover the depth of most root mass of agricultural plants as well as positive correlation to soil retention.

The result is a separate GIS layer made by combining information from point-measured soil data and the 1:25,000 soil map. It covers agricultural land within GPAs and is classified into 6 permeability classes. Permeability rates on national GPAs range from 10.1 cm/day to 1369.7 cm/day. Mean value is 130.8 cm/day, median 108.5 cm/day and standard deviation is 113.3 cm/day. Moderately permeable soils prevail (55 %), followed by low permeable soils (30 %) and poorly permeable soils (14 %).

The result of the study suggests that permeability of the most restricted areas is higher than on areas less restricted or without restrictions. The data will be used for reviewing groundwater protection regulations and, if necessary, proposing to redefine management restrictions in GPAs to increase local food production.

<sup>4</sup> Wageningen University, Department of Soil Quality, Wageningen, THE NETHERLANDS

International trade of agricultural products has complicated and far-reaching impacts on land and nitrogen use efficiencies. We analysed the productivity of cropland and livestock and associated use of feed and fertilizer efficiency for over 240 countries, and estimated these countries' cumulative contributions to imports and exports of 190 agricultural products for the period 1961–2017. Crop trade has increased global land and partial fertilizer nitrogen productivities in terms of protein production, which equalled savings of 2,270 Mha cropland and 480 Tg synthetic fertilizer nitrogen over the analysed period. However, crop trade decreased global cropland productivity when productivity is expressed on an energy (per calorie) basis. Agricultural trade has generally moved towards optimality, that is, has increased global land and nitrogen use efficiencies during 1961–2017, but remains at a relatively low level. Overall, mixed impacts of trade on resource use indicate the need to rethink trade patterns and improve their optimality.

#### DECOUPLING CROP AND LIVESTOCK PRODUCTION GLOBALLY

C. ZHANG<sup>1</sup>, X. LIANG<sup>1</sup>, S. KEE LAM<sup>1</sup>, B. GU<sup>2</sup>, D. CHEN<sup>1</sup>

<sup>1</sup> School of Agriculture, Food and Ecosystem Sciences, The University of Melbourne, MELBOURNE, &#28595;&#22823;&#21033;&#20122;

<sup>2</sup> College of Environmental and Resource Sciences, Zhejiang University, HANGZHOU, &#20013;&#22269;

Decoupled crop and livestock production systems, within the context of globalized trade and characterized by the overuse of synthetic nitrogen (N) fertilizers and insufficient recycling of manure, pose threats to both environmental and human health. Our synthesis of global agricultural production and trade data highlights the escalating prevalence of decoupling, illustrated by the global decline in the ratio of manure management N to crop removal N from 0.8 in 1961 to 0.3 in 2020. The global crop trade has surged 13-fold from 2.3 Tg N in 1961 to 31.7 Tg N in 2020, with the most significant increase observed in oilseeds trade, of which 58% is allocated for livestock feed. It is crucial to emphasize that resolving the decoupling of crops and livestock appears unlikely under the no-trade hypothesis, given the diverse N requirements among countries. Enhancing N management embedded in trade, reallocation of domestic livestock production space, and dietary changes, could enable the recoupling of crop and livestock systems, potentially reducing N losses by 65% and making a significant contribution to the achievement of multiple SDGs.

HOW TO RECONCILE THE POLICY OBJECTIVES OF FARM SUPPORT AND GREEN AGRICULTURE?

E. CHENG

The Ford Foundation, Beijing, CHINA

#### **Body**

The government fiscal and financial policies have played an important role in the productive use of land and land conservation and development. The channels through which the policies impacting on land and soil include the government subsidies on land use, agricultural input and output, and financial regulations on the entry of new types of financial institutions, the rate of interest, and loan securitization. This presentation focuses on two government policy initiatives in the Asian region: government subsidies on fertilizers and other farm inputs, and credit rationing closely associated with regulations on the rates of interest charged by formal and semi formal rural financial institutions. The presentation will also discuss how shall the policies respond to new challenges in land use, chiefly to support carbon smart sustainable agricultural development for the transformation of food and agricultural systems.

##### NITROGEN AND CARBON DYNAMICS IN ARABLE SOIL AS IMPACTED BY PRODUCTION INTENSITY OF MIXED ORGANIC DAIRY FARMING SYSTEMS

M. SPETH, I. MULDER, J. SIEMENS

Justus Liebig University, Giessen, GERMANY

The separation of crop production and animal husbandry in modern agriculture has led to decoupled nutrient cycles with nitrogen surpluses, declining soil organic matter stocks, increasing greenhouse gas emissions, and lower animal welfare. Organic mixed dairy systems, are considered to overcome these problems, but can differ in feeding and crop rotation, and thereby productivity. However, knowledge regarding the balancing of intensities with which mixed farming can meet the demand for organically produced food while minimizing environmental impacts, is required, but lacking.

In high-intensity farming systems, cattle are fed large amounts of protein-rich fodder leading to higher N concentrations in the manure. In low intensity systems, roughage with low N content predominates the animal diet, making room for crops for human consumption. Consequently, farm manures differ in quantity and composition, which influences the C and N dynamics in the soil. Carbon sequestration strategies face the challenge of increasing the C content in soils without increasing nitrogen fertilization or risking N immobilization. We hypothesize that C-sequestration improves under high-intensity farming systems due to the N nitrogen content of the manure.

This hypothesis is tested in the project "GreenDairy" at an organically managed experimental farm in Germany. Within the framework of the project, half of the trial area on arable land is converted to a lower farming intensity and the impact of organic milk production under low- vs. high intensity on humus and nitrate leaching is analyzed. At the beginning of the project, soils of the arable and grassland plots were sampled by core drilling. Changes in concentration and composition of the C and N fractions are measured semi-annually via soil coring for the extractable and continuously for the dissolved fractions using glass suction cups. Due to the variation in manure and crop rotation, changes in C- and N-dynamic are expected in the long term. These changes are expected to occur first in the dissolved and water-extractable C- and N-fractions.

##### TILLAGE AND HEMP RESIDUES EFFECT ON SPRING WHEAT YIELD

U STULPINAITE, V TILVIKIENE, G SIDLAUSKAITÉ

Lithuania Research Centre for Agriculture and Forestry, Kedainiai, LITHUANIA

Climate change and soil degradation are biggest threats to sustainable agrodevelopment there is demand for new solutions at the moment. In order to avoid catastrophic effects on global society, every effort should be made to keep the average temperature from increasing by more than 1.5°C compared to pre-industrial times. Therefore, in addition to the rapid reduction of greenhouse gas emissions, it is necessary to look for alternative methods for the accumulation of carbon and mineral substances in the soil. But not only climate change threatens the balance of planetary ecosystems. For example, soil degradation has resulted, among other things, from unsustainable farming methods and subsequent deforestation in search of new farmland, which also directly threatens global biodiversity, to soil sealing or compaction which leads to unfavourable farming conditions.

The aim of this study was qualitative and quantitatively determine how different tillage practices and hemp residues influence spring wheat yield. The experiment was conducted in Lithuania Research Centre for Agriculture and Forestry experiment fields, loamy soil. Spring wheat was sown 02/05/2022 – 08/05/2023, 210 kg/ha. Three treatments were selected, 1 – Control (without hemp residues, traditional tillage autumn) 2- Traditional tillage autumn added additional hemp residues, 3 – Traditional tillage early spring added additional hemp residues, 4 – no tillage hemp residues left on the top soil.

The results show that hemp residues and different tillage has influence on spring wheat yield. The highest spring wheat yield were determined in treatment 1 and 2 the lowest in treatment 4.

**Keywords:** Hemp,Residues,Soil,Tillage,Wheat

<sup>2</sup> FONDAZIONE BRUNO KESSLER, Trento, ITALY

Soil supports critical ecosystem services, whose recognition is growing in the scientific community and in multiple environmental policies. Therefore, soil monitoring and assessment initiatives have been put in place from the global level to the farm scale, passing through the EU. Considering the common soil understanding implicated in the sectorial environmental policies and the interconnections between the soil processes and functions, integration of the data and monitoring methodologies in a unique soil data commons platform is critically needed. Here, we present some concepts and implications of novel soil data commons that are conceived to interoperate within an ecosystem of data commons, potentially including the EUSO infrastructure, and report on a relevant activity in Italy.

For what concerns the governance, the soil data commons would be managed by the public institutions mostly contributing with both legacy and novel data. Some data and products would be open and used for citizen engagement and awareness, while the sensitive data would be accessed by public and private stakeholders with different privileges through authentication. Data feeding would be encouraged by granting the contributors more privileges and engaging them in the activities of the soil data commons community.

The soil data commons will host georeferenced multidiscipline, multisource and multiscale soil data from monitoring campaigns, research projects, land restoration activities, environmental assessments and farm monitoring. Data heterogeneity deepens understanding and promotes research questions but requires effective data curation. A quality flagging system would assign a confidence level to the data based on the metadata. A coherence flagging system would reconcile the data co-located in homogeneous areas for pedo-climatic conditions, land use and management. Data reconciliation could be made through conceptual modeling, potentially revealing the causal relationships between soil processes and external forcing. An adaptive monitoring system, shared within the soil data commons community, could complement the traditional monitoring campaigns by focusing on the priority areas characterized by poor data quality/coherence or exposed to intensifying environmental pressure.

There is an urgent need by the European Union to establish baseline levels for most pollutants (e.g., Potentially Toxic Elements (PTE), Polycyclic Aromatic Hydrocarbons (PAHs), microplastics and antimicrobials) and to define the sub-indicator soil pollution under the Zero pollution action plan. Hence, the main objective of the present analysis is to contribute to the general understanding of the pollution status of EU urban soils by preparing a systematic inventory. A comprehensive systematic map of the available literature on key urban soil threats such as PTEs, organic pollutants, microplastics, and antimicrobials does not exist. Through Scopus and Web of Science databases, the peer-reviewed scientific contributions that use the terms urban soil and (soil compaction, bulk density BD, soil organic carbon dynamics, microplastic, PAHs, antibiotics, PTEs, N and P, herbicides, pesticides) were included. In total, we analysed 2194 papers (after duplicate removal), of which about 1500 were irrelevant to the topics investigated (not about soil, no soil data provided). Notably, less than half of the records collected by keyword searching in the database were within the scope of the inventory compilation. The subset articles about urban soils were analysed to provide an overview of the current knowledge on urban soil threats, the geographic spread of this data, the breadth of the data, and bibliometric statistics on the dataset, and to compile an inventory that future research can build upon. The main threat identified by both the bibliometric and the systemic analysis is PTEs. This study fits in the frame of the Zero pollution action plan. It can suggest to policy stakeholders particular aspects that must be better considered in an urban context, such as increased research on soil reuse, sealing and compaction.

#### 3.04 133595 - Soil Governance to Prevent Loss of Fertile Lands: Soil Remediation and Photovoltaics

##### SUSTAINABLE SOIL MANAGEMENT IN HONDURAS

G.E. AREVALO DE GAUGGEL, C. G

ASOHCSUELO, Tegucigalpa, HONDURAS

An account of the most important soil studies in the history of the country is presented. Soil studies in Honduras started in 1880 with banana cultivation. Actually, soil studies are being conducted by the Honduran government, FAO, USAID, and private enterprises interested in melon, oil palm, bananas and coffee cultivation. The soil forming factors in Honduras are highlighted to assess their production potential and their sustainability. Soil degradation, process in mountainous and flood plain soils under cultivation are discussed aimed to secure their sustainability. The main processes of soil degradation identified are soil erosion, sedimentation, salinization-sodification, loss of soil structure and porosity, soil compaction, acidification, loss of biological activity, contamination, and urban expansion in agricultural soils. The soils of Honduras have a strong influence of topography, climate, and parent material. The soils with agricultural potential only comprise 12% of the country's territory making soil sustainability crucial for the future of the country. A Soil Conservation National Plan and a Land Use Legislation and implementation are strongly recommended as major components of an effective Sustainable Soil Management Plan.

**HARMONY BENEATH THE WHEELS: SOIL GOVERNANCE STRATEGIES FOR SUSTAINABLE GAME DRIVES IN WILDLIFE PROTECTED AREAS TO PROTECT SOIL HEALTH, BIODIVERSITY, AND WILDLIFE CONSERVATION**

G.P. NORTJE

University of South Africa, Florida, SOUTH AFRICA

This presentation aims to spotlight the escalating adverse effects of off-road driving (ORD) and underscore the critical role of soil governance in African wildlife protected areas within the context of ecotourism. Effective soil governance involves legal, political, and scientific management to enforce game drive and ORD protocols, ensuring sustainable land management and ecological well-being. Roads and road networks, pivotal for ecotourism, impact natural habitats and soils, both positively and negatively. Game drives, integral to the industry, bring tourists closer to wildlife, with ORD increasingly prevalent since 2000. While ORD offers unique wildlife encounters, it poses significant long-term harm to the environment, particularly the soil. Despite proven negative impacts, ongoing research seeks mitigation strategies for more sustainable game drives. This presentation focuses on highlighting these issues and emphasizes research efforts towards mitigating the negative impacts, aligning with UN Sustainable Development Goals, notably 'Responsible consumption and production' (12), 'Climate action' (13), 'Life on land' (15), and 'Partnerships for the goals' (17). Addressing soil governance in ecotourism contributes to broader sustainability objectives outlined by the United Nations.

#### 3.05 133724 - Industry, Policy and Science: Working Together for Meaningful Scaling of Soil Assessment and Climate Mitigation

**SOIL CONSERVATION WITHIN THE CAP: TWO DECADES OF PUBLIC SPENDING FOR SOIL CONSERVATION IN SPAIN.**

M. VAN OUDENHOVE<sup>1</sup>, P. PEREZ CUTILLAS<sup>2</sup>, C. BOIX FAYOS<sup>1</sup>

<sup>1</sup> Soil and water conservation research group, CEBAS-CSIC (National Research Council), Murcia, SPAIN

<sup>2</sup> Department of Geography, University of Murcia, Murcia, SPAIN

Measures for soil conservation were structured during two decades along the Rural Development Programs (RDPs) developed by the 17 Spanish Autonomous Communities (hereafter regions) following the European Common Agricultural Policy's (CAP) guidelines.

Besides the accuracy and detail of published regional statistics, a global picture of the spatial and temporal distribution of public spending at the regional level and the drivers for the allocation of resources is lacking. After two decades of implementation of public spending for soil conservation this work aims to analyse spatial and temporal distribution of direct and indirect measures for soil conservation applied within the Rural Development Programs in Spain, as well as the correlation with soil condition at a national level.

The methodological approach consisted in (i) a recollection (data mining) and inventory creation of agri-environmental and forestry measures aimed at soil conservation published by the Ministry of Agriculture; (ii) a spatial and temporal analysis of the measures' progress, and (iii) a preliminary exploration to the potential relations between the selected measures and soil condition, land use and socio-economic factors by using multivariate statistics. It was observed that public spending in RDPs decreased over the 3 programming periods, whilst public spending in measures for soil conservation increased. Also, distribution varied over the regions. Distribution of data revealed similarities among regions, as Principal Component Analysis showed clustering. Canonical Correlation Analysis results allowed to correlate patterns of public investment with other sets of variables. Erosive states in particular was found to be strongly correlated to public investment distribution, highlighting the importance of measures for soil conservation within RDPs, which act as a tool for regions and farmers to access finance and apply them where it is needed. It seems that the CAP's second pillar was during two decades a very effective tool for soil conservation policies in Spain. From 2023 onwards, all new rural development actions will be incorporated into national CAP strategic plans.

### 3.05 133724 - Industry, Policy and Science: Working Together for Meaningful Scaling of Soil Assessment and Climate Mitigation

#### DECARBONISING THE DEFENCE: EXPLORING SOIL-BASED SOLUTIONS FOR CLIMATE MITIGATION ON MILITARY SITES

C.F. ZANI<sup>1</sup>, A.S. BARNEZE<sup>1,2</sup>, D.A.C. MANNING<sup>1</sup>

<sup>1</sup> Newcastle University, School of Natural and Environmental Sciences, Newcastle upon Tyne, UNITED KINGDOM

<sup>2</sup> Centre for Ecology & Hydrology, Lancaster, UNITED KINGDOM

Record-breaking temperatures occur annually globally, coinciding with rising greenhouse gas (GHG) concentrations in the Earth's atmosphere. Immediate actions for cutting emissions and potentially advancing carbon (C) capture are required from all individuals and sectors, including energy, transport, agriculture, industry, and the military. A pioneering collaboration between Newcastle University and the UK's Ministry of Defence (MoD) has initiated a groundbreaking scientific project to decarbonise the UK's Royal Air Force (RAF) on military premises. The VITAL Living Lab project at RAF Leeming base conducts experiments, including one targeting C emission mitigation through soil C capture. In this context, there is a pressing need to assess "Frontier-technologies" such as the addition of crushed rock (Enhanced Rock Weathering-ERW) and biochar. This extends beyond C capture potential to also encompass broader benefits/impacts on soil health (chemical, physical and biological aspects), aboveground vegetation, leachates, and GHG emission. A mesocosm experiment was established combining different land uses: urban (garden and grass areas) and agriculture (conventional and organic agricultural systems), with the application of crushed rock and/or biochar to explore their individual and interactive effect on CO<sub>2</sub> fluxes, aboveground nutrient and potential trace metal uptake, and alkalinity, cations and anions efflux. Intact soil cores were extracted from the 0-0.45 m depth in 2023. Preliminary findings reveal notable changes in alkalinity (analysed using titration) likely associated with soil monoliths treated with crushed rock, which also alters the balance of anions and cations (analysed through inductively coupled plasma-optical emission spectrometry-ICP-OES). Changes in CO<sub>2</sub> flux (analysed by a portable gas analyser) do not appear to be influenced by crushed rock or biochar application but rather by different land uses and management systems. As one of the largest landowners in the UK, with an estate encompassing nearly equal to 2% of the country, the MoD stands to benefit from initiatives such as these, offering potential evidence of their ability to positively contribute to C removal from the atmosphere utilising military-owned lands.

<sup>5</sup> University of Pécs, Dept. of Earth Sciences, HUNGARY

Climate change, population growth, urbanisation and shrinking areas of arable land may increase the need for alternative and sustainable solutions to produce food in the future. Urban agriculture has many different forms, which can greatly contribute to the food security of the continuously increasing urban population. Therefore, a resilient urban planning should include the mapping and environmental assessment of unused or abandoned urban areas and green spaces to establish urban gardens, rooftop farming, vertical farming systems, community gardens and school gardens, parks, and green areas for recreation to design new and complete urban ecosystems. Furthermore, the environmental status and regional differences of soil conditions in these urban areas will determine future land use and environmental remediation strategies. This new development requires community participation and an inclusive approach to stakeholder management from the political decision makers. We must therefore strive to raise awareness of the importance of soil in urban environments, thereby promoting green, optimal urban design and management of natural resources. Soil conservation in urban and peri urban environments is a part of a resilient urban metabolism, based on total recycling, remediation of biodiversity and community participation supported by local and microregional green business models, which are both environmentally and economically viable. Therefore, urban planning practitioners need a strategic tool to transform the results of environmental and socio-economic assessments into urban actions, which must be integrated in the urban ecosystem planning process. The future is likely to include a combination of different ways for city dwellers to obtain their food. It is not to be expected that cities can grow all the food their citizens need, arable farming, wheat fields and potato fields will still be needed. But urban agriculture, as part of the sharing economy, can enhance the multifunctional use of land, combining food production with social inclusion, educational opportunities, and improved quality of life. We have therefore developed a multifunctional urban policy model focussed on organic urban agriculture with particular emphasis on regenerative soil management, development of green infrastructures, capacity building through practice-based formal and non-formal education programmes and support of local sustainable business initiatives to create new employment opportunities.

### 3.06 133726 - Potential of Soil Archives to Answer Management Questions Today

#### THE CREA SOIL ARCHIVE, A NATIONAL COLLECTION FOR ITALY. EXPOSING A TOOL TO ACCESS PHYSICAL SAMPLE AND DIGITAL DATA

G. L'ABATE, A. LACHI

CREA, Agriculture and Environment, Firenze (FI), ITALY

“The Archive’s soil specimens are invaluable time capsules for assessing temporal changes in soil properties” Physical samples are a basic element for reference, study, and experimentation in research. There is an urgent need for better integrating these physical objects into the digital research data ecosystem, both in a global and in an interdisciplinary context to support scientific reuse.

The CREA collection, located at the Experimental Farm of Fagna, Scarperia (FI), stores specimens and associated metadata. Part of collected samples was recently received and are temporarily stored unordered. It covers all major agricultural and forestry soil landscapes in Italy for organic and mineral horizons. Parameters include water impedance, rooting depth, stoniness, Coarse fraction, particle size, pH, organic carbon, and total carbonates, World Reference Base classification.

With the present work, a tool was developed to expose both metadata, digital research data, displacement to support FAIR principles. The tool was developed by means of Ms Power BI. The original local Ms Access database was stored on the cloud and connected to the tool to allow automatic updates. Geographic and semantic queries are graphically implemented through drop-down menus and pie charts on administrative units; Soil districts; European Environments; Land use; WRB; and Project.

The tool expose data collected by 13 different projects from 1986 to 2017. Contains 13,231 analyzed observations (pedological profiles, minipits, or augerings) for a total of 33,523 samples. Soil properties resulted in ranging for Clay: 0.1-93.5 (29.9 average); Sand: 0.0-99.4 (17.9), pH (water): 3.9-9.7 (7.5); Organic carbon: 0.0-53.4 (7.8); Total carbonates: 0.0-91.4 (5.5) for the whole dataset. Textural composition of every Reference Soil Group (24 out of 32) is presented as Bar Histogram. A navigation panel allows to preview the site location and storing collocation.

Although samples access is restricted, data and storing displacement are exposed to support use of the data and specimen's reuse. The developed tool represents a first attempt to expose both metadata, soil data and filtering capabilities.

### 3.07 133729 - Nitrogen Use Efficiency as Influenced by the Microbiome

**COMPOSITIONAL SHIFTS AND ASSEMBLY IN RHIZOSPHERE-ASSOCIATED FUNGAL MICROBIOTA THROUGHOUT THE LIFE CYCLE OF HIGH NITROGEN USE EFFICIENCY RICE UNDER INCREASED NITROGEN FERTILIZATION**

H. DONG

Liaoning Academy of Agricultural Sciences, Shenyang, CHINA

Soil fungal microbiomes facilitate a range of beneficial functions for their host plants, and rhizosphere fungal community composition, richness, and diversity affect plant growth and development, and crop yield. Therefore, exploring the community structure and assembly of the rhizosphere fungal microbiome and its relationship with soil biochemical properties are fundamental to elucidating how rice plants benefit from their fungal symbionts. In this study, soil samples were collected at the seedling, tillering, heading, and ripening stages of high nitrogen use efficiency rice variety, subjected to three levels of nitrogen fertilization. Plant growth demonstrates a substantial influence on fungal community composition and diversity. From the tillering to the ripening stage, the fungal communities were governed by homogenizing dispersal and dispersal limitation. The prevalence of Glomeromycota, the beneficial fungi, was considerably higher during the heading stage compared to the three other growth stages. This increase in abundance was strongly associated with increased levels of soil nutrients and enhanced activity of nitrogen acquisition enzymes. This strategy may be developed by rice grown in flooded soil to recruit beneficial fungi in the rhizosphere to meet high nitrogen demands. Our study findings contribute to elucidating the influence of plant development and nitrogen fertilization on the structure and composition of the fungal community as well as its relationship with soil key soil nutrient content and nitrogen-related enzyme activities. They also illustrate how a shift in the fungal community mediates and reflects the effects of nitrogen fertilization input in rice agroecosystems. These findings provide new insights into the effects of changes in nitrogen application in rice rhizosphere at different growth stages on fungal communities and soil biochemical characteristics.

## 3. Soil governance

### 3.08 133775 - Soil governance: building on stake-holders interactions and involvement for a sustainable management of soils

**JOIN THE SOIL CARBON INTERNATIONAL RESEARCH CONSORTIUM !**

S. REYNDERS

INRAE, Paris, FRANCE

Join the soil carbon community!

The Soil Carbon International Research Consortium (IRC) was launched during Soil Mission Week in Madrid. It is supported by ORCaSa - a three-year Horizon Europe initiative -, and its 5 regional nodes. Hand in hand with the 4p1000 Initiative, the Soil Carbon IRC covers all soils: agriculture lands, forests, pastures, wetlands, urban areas, etc. You can already join the Soil Carbon IRC! Depending on your expertise and type of involvement, you will be part of one of the three colleges (researchers, funders, and users), and included in the regional node corresponding to your location.

Targeted services delivered by the Soil Carbon IRC:

#### 1. Harmonisation MRV framework

You can be part of an international community truly committed to raise awareness and develop scientific knowledge on how to measure, report and verify soil carbon stock changes by contributing to an internationally harmonised Monitoring, Reporting, and Verification (MRV) framework

#### 2. Open access knowledge platform

You can access and contribute to a knowledge platform driving you to:- scientific evidence through meta-analysis and reviews- description of best practices from verified sources- interactive mapping of data (for instance, easy visualisation of carbon stock and its evolution) - initiatives, projects, and a large network of stakeholders.

#### 3. Research alignment and calls

You can contribute to an aligned Strategic Research and Innovation Agenda (SRIA) that will consider all types of land use in each region to ensure that soils play a role in soil health and innovation for climate change mitigation and adaptation. In addition, you will access to funds designed to facilitate international collaboration between projects. The Soil Carbon IRC will propose calls dedicated to the implementation of the SRIA and negotiate them with international funders.

## 3. Soil governance

### 3.08 133775 - Soil governance: building on stake-holders interactions and involvement for a sustainable management of soils

**PRIME FARMLAND SOILS ARE UNIQUELY VALUABLE FOR THEIR ECOSYSTEM SERVICES, BUT ALSO UNIQUELY VULNERABLE TO UNPRECEDENTED LAND TAKE AND SOIL SEALING**

L. PEAKE

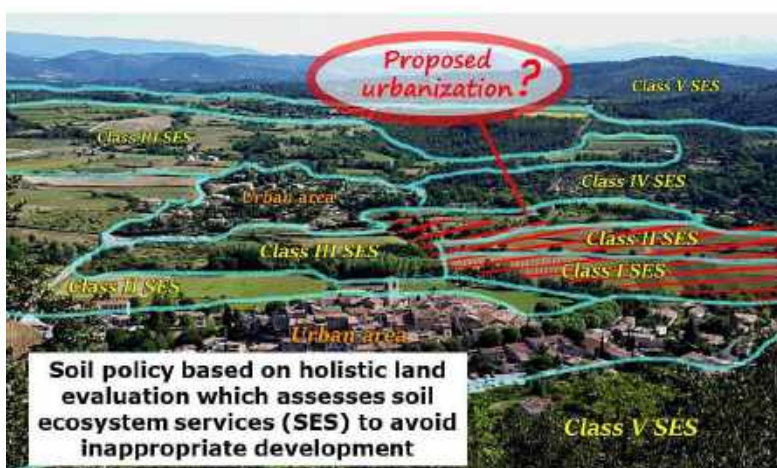

University of East Anglia, NORWICH, UNITED KINGDOM

Resource-rich soil, often referred to as prime farmland, provides optimal food and fibre, and a high degree of less tangible soil ecosystem services (SES), e.g. the storage and filtration of water, a genetic reservoir, carbon sequestration and the ability to incorporate biological waste. However, spreading urbanisation and infrastructure incurs land take and irreversible soil sealing, the most extreme form of soil degradation, which largely eradicates in situ SES. The result is further ecological loss and diminution of our resilience in the face of climate change, e.g. flood and drought mitigation. Since high-grade soils typically provide more SES than any other type of land, their sealing will have the greatest environmental impact.

Yet it is precisely such land that is often at most risk of development. Its proximity to urban centres makes it accessible and close to infrastructure, and it is cheaper to develop than brownfield land. Escalating land prices encourage farmers to sell, often to pay off debts. In the 20th century, agriculture was intensified by technology, fossil fuels and government incentives to maximise production. Now that the focus has shifted to pollution, climate change and ecology, agriculture is increasingly pilloried as an enemy of Nature. Consequently, agricultural land is often seen as having less intrinsic value than natural ecosystems. Furthermore, soil does not invoke the emotive responses associated with wildlife or landscape and its loss often goes unnoticed.

There is an urgent need to prioritise prime farmland preservation (PFP), as well as conserving natural ecosystems. Development needs to be more innovative in its use of space, but also directed at brownfield sites, low-grade soils and other marginal land of low landscape or ecological value. Fewer than a third of the world's countries have policies to discourage the loss of prime farmland and, of these, just a handful have stringently enforced laws to this effect. PFP deserves to become one of the highest priority global soil governance issues.

The SERENA Project (EJP SOIL) aims to improve the effectiveness of European environmental policies, and in particular those on soil health, through the analysis of soil threats and soil-based ecosystem services in European agricultural landscapes. The need for good agro-management practices and techniques to contribute to the improvement of soil health and to mitigate the effects of and adapt to anticipated global change scenarios have been widely recognized. The predicted effects of global changes make it necessary to properly inform stakeholders about risks under future scenarios. To contribute to the improvement of soil health and to mitigate and adapt to the effects of global changes, it is important that people are made aware of the benefits of sustainable cropping systems and the implementation of beneficial for the soil agro-management practices and techniques. With information taken from literature and in collaboration with stakeholders, this study focuses on defining the relevant scenarios for agricultural soils. The main drivers of change considered are climate change, demographic trends, changes in land use/land cover as well as land management. Stakeholders have been asked to identify potential mitigation entry points and have been offered the possibility to share their opinions and expertise on the outcome of the scenario analysis and the resulting implications for soil health and ecosystem services. The results indicate that further consideration must be given to how best to raise awareness among stakeholders on aspects of soil health. Here especially, the importance of soil threats and soil ecosystem services in maintaining soil health should be acknowledged. The scenario co-creation process with stakeholders plays a key role in evaluating the effectiveness of soil related policies in striving to achieve national and global environmental targets, including Agenda 2030 and its Sustainable Development Goals, the provisions given in the Rio Conventions, in the European Green Deal, and the proposals contained in the new EU Soil Law.

The small island of Montecristo, one of seven islands in the Tuscan Archipelago of Italy's Tyrrhenian Sea, is a natural reserve since 1971 and it has been awarded in 1988 by the Council of Europe with the European Diploma of Protected Areas. It is included in the National Park of Tuscan Archipelago since 1996. State Forestry Corps (CFS) administrated the Protected Area until 2016, then and to date it is managed by Carabinieri Biodiversity Office of Follonica. In the past, the CFS has successfully managed several LIFE Nature projects for the conservation of both species and habitats of EU relevance. However, limited attention has been paid in relation to soil protection and to its ecosystems services. Therefore, the aim of this research is to map soil units via conventional soil surveys, laboratory analyses and GIS approach in order to provide useful soil guidelines for local land planning strategies. The soil mapping of the island required an intensive level of field investigation and sampling based on survey fieldwork due to the challenging environmental setting. The spatial distribution and variability of the most extensive soil types were reproduced in GIS and presented in a pedo-landscape map, with a descriptive legend based on World Reference Base classification. Five RSGs have been identified: Leptosol, Regosol, Cambisol, Umbrisol, Kastanozem. Several soil types were resulted highly affected by soil erosion processes. We applied a GIS based analysis using the RUSLE model to estimate annual soil loss on pixel level (25 m<sup>2</sup>) and to assess the spatial distribution of soil erosion in the study area, following several methodological improvements of the new JRC modelling assessments. This knowledge might be very useful for stake-holders to prepare the area and to identify the hotspots for erosion and for SOC preservation that might need intervention measures. In fact, soil erosion can affect SOC content and that is of great importance because of global environmental concerns.

How do soil scientists perceive and experience soils? They use a wide variety of devices and tools, such as microscopes, laboratory equipment and field campaigns, and they summarize their knowledge through publications, graphs, and tables. Approaching soils with this academic perspective is likely to cause scientists to have different relationships with soils than people without soil science training. Humans have relationships with soils, and in addition to the science-based ones, these relationships can be personal, artistic, cultural, sensorial and more. Clearly, soils matter at many levels since people and communities can feel a deep connection with the soil of their homeland, as a source of identity, sustenance and a sense of place and belonging. What we proposed during the Wageningen Soil Conference was to let soil scientists discover the diversity in ways that soils can be experienced and perceived. During these event we took participants beyond the scientific perspective in an informal and relaxed space where we engaged with soils in unexpected and creative ways. Seventeen 'stations' were dedicated to experiencing colors, smells, tastes, textures, sounds, visuals, emotions and feelings peculiar to soils. Each station was organized by either a scientist or an artist that was present to encourage discussions, conversations and sharing of stories to inspire to experience new soil perspectives. One of the goals of this exercise was to expand the, often narrow, view of soil scientists on soils and let them discover other dimensions which can allow them to better connect with society and inspire them to share their work and knowledge about soil. This event was just the beginning of our collaboration towards experiencing soil perspectives and in the future more events using the same or a similar format for different stakeholder groups (non-soil scientist, general public) are going to be organized. During the conference we will share our concept, experiences and reflection with a broader group of soil scientists.

##### A CHANGE IN THE APPROACH TO PROTECTING AGRICULTURAL LAND IN POLAND

K. KOLINSKI

Adam Mickiewicz University, Poznan, POLAND

Apart from the obvious benefits, Poland's constant development also has negative consequences. One of them is the constant loss of agricultural land, which is being transformed into urbanized land. This situation is a consequence of the country's inappropriate spatial policy. The development of buildings in Poland is carried out in a chaotic manner. As a remedy, it was decided to introduce a new act on spatial planning. According to the author, the act will significantly inhibit the uncontrolled development of buildings. Thanks to the changes, agricultural land will be better protected and its loss should be stopped. The aim of the poster is to present the current changes in agricultural land and to present potential instruments that inhibit these processes.

**Keywords:** development, agricultural land, spatial chaos, loss of agricultural land

<sup>5</sup> Vytautas Magnus University Agriculture Academy, Kaunas, LITHUANIA

<sup>6</sup> University of Wyoming, Laramie, USA

The experiment was established in Skierniewice (central Poland) on sandy loam Luvisol, which received mineral fertilizers (CaNPK). The treatment included: control; manure; legumes; and manure with legumes. Soil samples from A horizon were collected during the 2022 mid-growing season and analyzed for total organic carbon; plant available water, the fractional composition of humic substances (HS), and spectroscopic properties of SOM and isolated humin fraction (HUM). Soil moisture, soil temperature, and CO<sub>2</sub> emissions were measured in the field during the 2022 and 2023 growing seasons.

The greatest impact on SOM content was observed in plots where manure had been applied. The fractional composition of HS revealed that the transformation of organic matter under fertilization with manure led to significant increases in the humic acids/fulvic acids ratio compared to the control, while the application of legumes caused a decrease in HUM vs. manure alone. Changes in the spectroscopic properties of HUM, and an increase in absorbance and fluorescence emission in legume-applied soil were detected.

Thermochemolysis and gas chromatography/mass spectrometry (TC-GC/MS) showed no general order for the relative abundance of compound classes carbohydrates, lipids, and lignin building blocks. Manure enriched HUM with lipids relative to the control whereas HUM in legume treatments had more lignins than the others. Most striking was the carbohydrate enrichment in the combination of manure and legumes.

Changes in the amounts and properties of SOM influenced water holding capacity. Manure fertilization significantly increased plant available water, while legumes alone decreased.

Based on the two years of monitoring, CO<sub>2</sub> emissions were affected by soil temperature only.

The results confirmed the beneficial effect of long-term organic fertilization on carbon dioxide sequestration. Furthermore, long-term different soil management practices not only altered the SOM contents and resulting chemical and physical properties but surprisingly also the chemical composition of HUM, which is considered as particularly stable and a long-term sink of atmospheric carbon.

The research was financed by EJP SOIL program, NCBR project EJPSOIL/I/78/SOMPACS/2022.

### REGENERATIVE AGRICULTURE : A MODEL TO EMULATE

R. RAMESH, D.P. SINGH

Higher Education Government of H.P, Shimla, INDIA

The regenerative agriculture is a dynamic system which webs all aspects of agriculture-which grow, enhance, exchange, distribute and consume goods and services. This system has holistic principles which restore soil and ecosystem health and addresses inequity and leaves our land, water, and climate in better shape for future generations (UN sustainable development). The customary and indigenous practices in India symbolize the bond between man and nature needs to be revived. The regenerative agriculture pattern which existed traditionally in India was based on the experiences of generations that focus on improving soil health, increasing biodiversity, and restoring ecosystems. It involves practices like minimal ploughing, crop rotation, and the use of organic fertilizers. It addresses soil degradation caused by intensive farming, enhances soil's ability to store carbon dioxide, and helps mitigate climate change by turning agricultural lands into carbon sinks. The key practices include reducing soil disturbance, rotating crops to improve biodiversity, using natural fertilizers, and managing grazing patterns to prevent soil degradation. Benefits include improved crop yields, enhanced soil health, reduced emissions, increased carbon sequestration, and greater resilience against climate change impacts. Himachal Pradesh is a small State in India 90 percent of its population live in rural area and 70 per cent are directly dependent on agriculture for their livelihood. Under the natural farming system, 3 to 12 crops are cultivated together on the same area. This study is undertaken to document the regenerative agriculture in India with its focus on Himachal Pradesh and regenerative farming practices which contribute to combat climate change in multiple ways; as agro-forestry and multi- cropping, often involve the cultivation of diverse crop species. There is a diversity of customs and traditions which results in vividness in the conservation practices.

The study intends to give a model based on success stories of the farmers and that of the State based on customary practices. This study will also incorporate the lived experiences of farmers.

### BIO-TILLAGE: A NEW PERSPECTIVE FOR SUSTAINABLE AGRICULTURE

X. PENG, Z.B. ZHANG

Institute of Soil Science, Nanjing, CHINA

For sustainable agricultural production, we propose bio-tillage, which is defined as improving soil structure with plant roots to boost the growth of crops. Cover crops with thick and deep roots can be used for bio-tillage since they can effectively improve soil structure and water and air conductivity by forming biopores (root channels), which provide space with the least resistance and a high level of oxygen and nutrients to promote root growth. The effect of bio-tillage on crop yields varies with climate conditions and management practices. An effective bio-tillage cover crop should have thick and deep roots with rapid root growth rates, rapid decomposition of remnant roots, and good adaption to climate and soil constraints. Planting cover crops in a timely manner and eliminating them at a suitable stage with a roller-crimper can benefit bio-tillage.

The bio-pores, created by cover crop roots, are cylindrical, continuous, and stable and facilitate the transport of air and water. The soil around biopores also affects plant growth by its rich nutrients. The behavior of roots encountering biopores is impacted by soil strength, oxygen concentration, biopore characteristics, and crop species. For example, the effect of biopores on crop growth depends on biopore size. The smaller biopores (<2 mm) promoted plant growth, but the larger biopores did not (>2 mm), which was mainly related to the degree of contact between root and soil in biopores. The limited understanding of ideal biopore architecture for root growth, more effective bio-tillage cover crop species, and field management of bio-tillage, needs to be addressed before a wide application of bio-tillage.

### CAN SMARTPHONE APPLICATIONS REVOLUTIONISE HOW WE MEASURE AGGREGATE STABILITY?

K. MUNISATH<sup>1</sup>, S. HAEFELE<sup>1</sup>, A. GREGORY<sup>1</sup>, N. OSTLE<sup>2</sup>

<sup>1</sup> Rothamsted Research, Harpenden, UNITED KINGDOM

<sup>2</sup> Lancaster University, Lancaster University, UNITED KINGDOM

Aggregate stability describes the ability of soil aggregates to remain stable against external forces such as rapid wetting and raindrop impact. Stable aggregates can improve soil structure, water holding capacity, and protect organic matter. Aggregate stability is therefore an important physical indicator of soil health. Current methods to measure aggregate stability often involve disrupting soil aggregates in distilled water. These tests are time consuming, require specialised equipment and are usually done in laboratories.

The Soil Aggregate Stability (SLAKES) smartphone application, developed by the University of Sydney, Australia, quantifies aggregate stability by measuring how quickly soil aggregates disintegrate once submerged in water. The SLAKES application requires three soil aggregates between 2-15 mm in diameter to be placed in a petri dish. Water is added and the SLAKES app provides a measurement of aggregate stability within 10 minutes.

To determine the sensitivity of the SLAKES app, we compared its aggregate stability measurements with that of the established "Le Bissonnais" method. Soil samples of different texture were taken from fields under fallow, permanent grass, and continuous arable cropping management at two experimental sites on different soil types. The results of the SLAKES app were similar to the results achieved with the standard "Le Bissonnais" method. The SLAKES app was able to differentiate between different managements on clayey soil but it was less sensitive when tested with sandy soil. Despite this, the SLAKES app is a legitimate method to measure aggregate stability. The app offers a simple, fast, and cheap alternative to standard laboratory methods, allowing land managers and non-scientists to actively test the quality of their soils.

<sup>2</sup> University of Padova - Department of Agronomy, Food, Natural Resources, Animals and Environment, Padova, ITALY

<sup>3</sup> University of Bologna - Department of Agricultural and Food Sciences, Bologna, ITALY

<sup>4</sup> University of Georgia - Crop and Soil Sciences Department, Athens, USA

Water-extractable organic carbon (WEOC) fractions are reliable and sensitive indicators for monitoring soil organic carbon and assessing the effectiveness of soil policies. However, determining WEOC pools is a time-consuming process. The aim of this study is to validate new methodologies for the fast determination of cold (CWC) and hot (HWC) water-soluble carbon, using high-temperature combustion and visible and near-infrared (VNIR) spectroscopy.

100 topsoil samples were collected from three long-term experiments in 'L. Toniolo' farm (Legnaro) on four different types of soil. Total organic carbon (TOC), CWC and HWC were analyzed at temperatures ranging from 200 to 600°C. VNIR spectral data were collected in laboratory from bulk soil and modeled using PLSR and cubist. Fourier Transform Infrared (FTIR) analysis was used to provide molecular information on bulk soil samples, CWC and HWC residues before and after heating.

Significant correlations ( $0.7 < r < 0.9$ ) were observed between CWC500, HWC300-400 and TOC300-400-500-600 in sandy, clay and peaty soils. PCA plot showed that CWC500 grouped with HWC pools and clay. Weak relationships ( $0.4 < r < 0.55$ ) were found for OC pools at 200°C, and between TOC, CWC and HWC in silty-loam soil. CWC300-500 and HWC300-500 exhibited higher sensitivity to texture and applied treatments. Before heating, the signal intensity of FTIR spectra was stronger in HWC than CWC. Most of the spectra presented bands associated with carbonyls, carboxylates, aromatics and carbonates. HWC300-400 and CWC300-400 residues underwent structural changes due to decarboxylation and condensation reactions. PLSR model performed better with respect to WEOC ( $r^2 = 0.66$  vs  $0.60$  and  $RPD = 1.7$  vs  $1.38$ , on average). Even more promising results were obtained for TOC content ( $r^2 = 0.93$  and  $RPD = 3.98$ , on average).

These initial findings indicate the potential for utilizing rapid techniques to quantify water-soluble carbon. Further analyses are imperative to implement proximal and remote sensing techniques.

Project funded by the European Union - NextGenerationEU, under the National Recovery and Resilience Plan (NRRP)

## 4. Soil health in achieving the Sustainable Development Goals 4.02 124990 - Towards harmonized soil health monitoring. Novel methods and perspectives and scientific, institutional, and societal challenges

### ACCOUNTING FOR SOIL HEALTH - CORPORATE SUSTAINABILITY REPORTING PERSPECTIVES

N. PAWSEY

Charles Sturt University, Albury, AUSTRALIA

Recent years have seen significant growth in sustainability reporting disclosures by corporate agribusiness entities. These trends have been stimulated through growing interest in sustainable agricultural investments and facilitated by the advancement of a number of international sustainability reporting initiatives including the European Union's Corporate Sustainability Directive and the International Sustainability Standards Board's climate and sustainability-related disclosures projects. These developments, however, have largely overlooked soil health and the significance of soil-related risks.

This project sought to understand the potential usefulness of soil-related disclosures to agri-investors and identify relevant means of advancing soil reporting by corporate agribusinesses. This is an important area of development given the impact of corporate agribusiness activities on soil health and increasing agri-investor exposure to soil-related risks.

A mixed-method research approach was deployed. This included data gleaned through an archival review of current annual report and other disclosure practices by corporate agribusiness entities and in-depth interviews with agri-investors and senior corporate agribusiness managers.

Results from the analysis of archival data identified few existing examples of comprehensive soil health information by corporate agribusinesses. Interviewees acknowledged the importance of soil health in maintaining agricultural productivity. There was a strong backing for the focus on enhancing soil reporting, including the disclosure of soil-related risks, strategies, metrics, and objectives. However, in recognition of the diverse and complex nature of soils, respondents acknowledged the challenge of reaching a consensus on standardised soil metrics. Should soil reporting advance, there was a preference for presenting soil-related information in a simple, concise manner, using terms and benchmarking approaches familiar to investors. This information on soils should be linked to other environmental-related matters and the financial ramifications associated with soil-related risks and opportunities should be clear. Additionally, any information conveyed to investors should be aligned with the types of information already utilised by agribusinesses for their internal management purposes. Doing so should help to minimise the reporting burden on reporting entities.

In the Mediterranean region, and in particular in the Near East and North Africa Mediterranean (NENA) countries, there is urgent need to enhance availability and use of soil data and information (SDI) and define harmonized methodologies to realize standardized soil information systems (SIS) as enabling conditions to monitor and improve soil health and support policies to achieve land degradation neutrality (LDN) and other Sustainable Development Goals. In the framework of the PRIMA-funded SOILS4MED project, all the countries involved are collaborating to create a country-owned standardized soil information systems (NSIS) to collect and manage harmonized SDI. Some NENA countries involved in the project, such as Tunisia, have various SDI collected across many decades since the mid-1900s, but often stored in non-digital format, poorly accessible, yet not standardized and harmonized. The NSIS will facilitate the management, update, visualization and use of the data. It will include existing soil point data and maps, and laboratory data, that will allow to produce soil quality, indicators, soil fertility, soil constraints, soil degradation and land capability maps. The NSIS, in Tunisia, will be first used to update the agricultural map, of primary importance for rural development plans, and secondarily to implement models and pedotransfer functions to calculate erosion rates and risk, and physical properties (e.g field capacity, erodibility, water infiltration, proneness to compaction, and salinization), fundamental for crop performance evaluation and improvement, and for mitigating of environmental degradation and restoration planning. The NSIS will also allow assessing and monitoring the efficiency and sustainability of land uses and management practices. The NSIS will implement in use cases embedded in Soil Living Labs (LL) established in Tunisia. A use case is the connected flows of actions defining the interactions between agricultural actors and NSIS, as well as other relevant data and tools, to achieve specific objectives. .

<sup>3</sup> Geographical Institute, Research Centre for Astronomy and Earth Sciences, Budapest, HUNGARY

The available literary data suggest the general applicability and benefits of the Matrix-assisted laser desorption/ionization (MALDI) time-of-flight (TOF) mass spectrometry (MS) in the field of microbiological identification including food quality and safety, and the clinical field. Since microorganisms are present in large numbers in the soil, our study aimed to examine the protein composition of the soil in a long-term detritus manipulation experiment on luvisols. The experimental sites were previously conducted with the following treatment in an oak wood forest. Double Wood, double litter, no litter, no woods, and no input. Soil samples were collected from the 0–5 cm layer in mineral soil twenty-three years after the treatments were established in the early autumn period. Different pre-digestion treatments were used to extract the protein content of soil samples was performed. The filtrates were then analysed by a MALDI-TOF MS. 1 µL of the sample was dropped onto a slide, and after drying, 1 µL of 70% formic acid was 6 of 14 added. Finally, it was sealed with 1 µL a-HCCA (a-cyano-4-hydroxycinnamic acid in 50% acetonitrile and 2.5% trifluoroacetic acid) matrix. The measured mass spectrum of the preparations was in the range of 100–1200 Da. A peak list was created from each spectrum, and then these peak lists were averaged per treatment. During the evaluation, we calculated with normalized intensity values, that is, the intensity values belonging to each point were divided back by the intensity value of the base peak. A cluster analysis was then performed on the normalized data. It can be concluded that the NI and NL treatments were significantly different from the other litter treatments and from the Control. The spectra of the DL and DW treatments and the Co and NR treatments showed close similarity in the different extraction methods.α

Soils play a crucial role in ecosystem functioning that provides multiple ecosystem services making human livelihood possible and environmental sustainability. The soils of the Mediterranean region (MR), particularly in the Near East and North Africa, are degraded due to prolonged unsustainable management and effects of climate change. In NENA region, soils are weakly developed, naturally low in organic carbon, and vulnerable to degradation processes widespread in the region (e.g. erosion, salinization). The amount of fertile arable land is continuously decreasing and increasingly contaminated. The improvement of soil management to achieve land degradation neutrality urgently needs a regional soil health assessment framework with comprehensive, relevant indicators and measuring methods. However, soil health indicators and methodologies for soil sampling and analysis may differ across countries, requiring harmonization. The PRIMA-funded SOILS4MED project develops conceptual frameworks to define quantifiable indicators of soil ecosystem services, soil quality and soil health adapted to the environmental conditions, soil types, and stakeholder needs. The approach is inspired to that adopted in Europe by the EJP Soil project, the LUCAS programme, and by FAO/GSP, and will be mostly based on data that are available in each country. The development of health indicators using various soil properties require to establish threshold values to define the soil is healthy or not healthy and to decide upon the weight of each property in the assessment of soil health, which may vary depending on local environmental conditions, policy objectives, and stakeholder perception. This might be a challenge at the scale of the studied MR as pedoclimatic and socio-ecological conditions are highly variable and soil management systems. The project will implement Living Lab-embedded use cases that are connected flows of actions defining the interactions between agricultural actors and country-own soil information, as well as other relevant data and tools, to achieve specific objectives. The Living Lab approach with explicit use case implementation will harmonize and test the soil health assessment framework with multi-level stakeholders.

##### TOWARDS ZERO POLLUTION AND IMPROVEMENT OF FERTILIZER QUALITY AND SAFETY: STANDARDIZED HEAVY METAL ANALYSIS

S. USTINOV<sup>1</sup>, V. SAYNES SANTILLAN<sup>1</sup>, H. RODRIGUES<sup>1</sup>

<sup>1</sup> Food and Agriculture Organization of the United Nations, Rome, ITALY

<sup>2</sup> Thornton Laboratory, Tampa, USA

Heavy metal content, particularly cadmium, copper and uranium in some of the raw materials used to manufacture phosphate fertilizers creates severe and difficult-to-reverse health problems for soils, crops, products, animals, and people. This poses a significant challenge to achieving the objectives of the One Health approach. The evaluation of fertilizer quality and safety is an essential step in moving toward a healthier and more sustainable use of mineral fertilizers, especially those containing phosphorus, because of their relevance in the productivity of agricultural systems. Given this scenario, the FAO-Global Soil Partnership is acting toward safer and sustainable use of fertilizers and eliminating soil pollution through the collaboration of the International Network on Soil Pollution (INSOP) and the International Network on Soil Fertility and Fertilizers (INSOILFER). In joint efforts, the two networks are working on evaluating and monitoring heavy metal content in phosphate fertilizers. Laboratory analyses are a primary step in assessing the quality of fertilizers that have significant impacts on soil quality. This work presents the process of harmonizing the standard operating procedure (SOP) for determining the heavy metal content in phosphate fertilizers. The SOP was developed through extensive collaboration with soil laboratories around the world, who shared their analytical procedures with the two networks of the Global Soil Partnership.

### THE RECSOIL INITIATIVE CONTRIBUTION TOWARDS LAND DEGRADATION NEUTRALITY AND SOIL HEALTH

C. OLIVERA, C. FERRO, M. BROWN, N. RODRIGUEZ EUGENIO

Food and Agriculture Organization of the United Nations, Rome, ITALY

Because soil organic carbon (SOC) is a key factor for soil health and land restoration, SOC stocks are one of the three metrics currently used to assess land degradation within Sustainable Development Goal (SDG) Indicator 15.3.1. Therefore, long and short-term development and investment decisions addressing the evaluation, prevention and restoration of degraded lands under the Land Degradation Neutrality (LDN) framework of the United Nations Convention to Combat Desertification (UNCCD) require integrated strategies to increase SOC stocks. The RECSOIL initiative for recarbonizing global soils provides a method to increase and monitor soil organic carbon stocks, making RECSOIL a valuable tool in achieving LDN targets.

While enhancing the implementation of the LDN framework, site-specific strategies to recarbonize soils are also capable of improving ecosystem services through enhanced soil health. RECSOIL promotes the adoption of sustainable soil management adapted to the local context, which ensures that soils have “the ability to sustain the productivity, diversity, and environmental services of terrestrial ecosystems” according to the definition of soil health by the Intergovernmental Technical Panel on Soils (ITPS, 2020). A healthy soil with a high SOC stock is usually more resilient and contributes to climate change mitigation and adaptation and to biodiversity objectives, as per the other Rio Conventions on climate change and on biological diversity (UNFCCC and CBD, respectively). SOC is also recognized as major topic in the Koronivia Joint Work on Agriculture (KJWA).

Here we present the RECSOIL initiative and toolkit for soil recarbonization monitoring, sustainable management, and decision support, highlighting their advantages in terms of a sound and sustainable implementation of the LDN framework. The aim is to share experiences, highlight barriers for implementation and receive feedback on the overall usefulness of the RECSOIL approach for LDN. Potential contributions to the implementation of the other Rio Conventions will be also discussed in pursuit of increased impact.

<sup>2</sup> Greenotec ASBL, Les Isnes, BELGIUM

<sup>3</sup> UCLouvain - Earth and Life Institute - Agronomy (ELIA) - Sytra, Louvain-la-Neuve, BELGIUM

Climate change, especially through the frequency of extreme climatic events like heavy rain, directly impacts soils, one of the most important components for sustaining agro-ecosystems. Intensive farming practices can also significantly affect soils, leading to a decrease in organic matter content, a loss of biodiversity, and heightened susceptibility to erosion. Recognizing these challenges, some farmers are adopting innovative soil management practices to protect or restore agricultural soil fertility in its three components: biological, physical, and chemical.

A new measurement protocol, the QuantiSlakeTest (QST), has been developed to assess soil structural stability. The QST is a low-tech method that continuously measures the disintegration of a soil sample submerged in water. Initial applications of QST in Belgian long-term experiments have confirmed the benefits of reduced tillage on soil structural stability and shown the advantages of this novel approach (Vanwindekens & Hardy, 2023).

Based on these promising findings in controlled conditions, the QST was implemented in real farms through three projects led by researchers or advisors from a support organization of the Walloon agricultural sector. The three case studies aimed to compare the impact of practices related to (i) the establishment and management of intercropping cover, (ii) the diversity of technical choices of farms engaged in conservation agriculture, and (iii) soil management in sugar beet cultivation.

Overall, the results from the three case studies confirm the relevance of the QST, even in contrasting pedoclimatic conditions at a regional scale. Specific findings highlight (i) that there is lower soil structural stability in fields that are tilled for sowing or/and destroying canopy of cover crops and (ii) the added value of temporary grassland in crop rotation. Our approach has further potential for implementing the QST in regional or national soil monitoring networks.

### INTRODUCING A NATION-WIDE AGRICULTURAL SOIL MONITORING IN SLOVENIA

A. GERLUSNIK<sup>1</sup>, B. VRSCAJ<sup>1,2</sup>

<sup>1</sup> Agriculture Institute of Slovenia, Department of Agricultural Ecology and Natural Resources (DAENR), Ljubljana, SLOVENIA

<sup>2</sup> Faculty of Environmental Protection, Velenje, SLOVENIA

In 2022, several paragraphs were added to the Slovenian Agriculture Act, which oblige the Ministry of Agriculture, Forestry and Food (MAFF) to finance regular monitoring of soil condition. The law defines soil parameters, analysis methods and a hierarchical structure of institutions responsible for the annual monitoring of agricultural soils. In 2022, MAFF initiated a five-year pilot project to develop a new nationwide Agricultural Soil Monitoring Programme (ASMP). The Agricultural Institute of Slovenia (AIS), the leading national agricultural research institute, was commissioned to organise and manage eight regional agricultural advisory services. After initial seminars on the correct and uniform soil sampling technique, soil samples were taken at 250 locations to a depth of 30 cm. The resulting 560 samples were analysed for a number of soil parameters: texture, acidity, nutrient and SOM content, CEC and heavy metals as well as organic pollutants. At the same time, the harmonisation and standardisation of laboratory analyses was carried out in national laboratories. In Slovenia, the predominant land uses are arable lands and meadows. On 161 sampled arable lands, the mean soil acidity was measured at pH 6. The soil here shows a plant-available phosphorous content of 15.7 g/100 g and a potassium content of 21.2 g/100 g. Additionally, the average soil organic matter is noted to be 3.6%. In contrast, on 70 sampled meadows, while sharing the same average soil acidity of pH 6 as arable lands, exhibit significantly different nutrient levels. The phosphorous content in meadow soils is much lower at 5.9 g/100 g, and the potassium content is 15.7 g/100 g. However, meadows have higher soil organic matter content, averaging at 6.5%. The first development and testing phase of the ASMP has been completed. The ASMP will be further expanded and refined. The knowledge gained will contribute to the fine-tuning of the system. If necessary, the ASMP will be adapted to the requirements of the recently discussed EU Soil Monitoring Directive.

### ASSESSMENT OF P MINERALIZATION FROM POULTRY MANURE, ORGANO-MINERAL FERTILIZER AND COMPOST THROUGH AN INCUBATION EXPERIMENT

V. TAKATA, A. DEL PINO, G. ARRARTE, L. ROGEL, M. FAGUNDEZ, B. ROMANO

Facultad de Agronomía, Montevideo, URUGUAY

This study was aimed to evaluate different strategies processing poultry manure, in order to offer environmental acceptable solutions to its disposal for the poultry industry of Uruguay, producing P rich soil amendments. The mineralization of organic amendments in the soil can be affected by the sources of organic materials and their physical form. We evaluated P availability after the addition of poultry manure, organo-mineral fertilizer, washed solids, compost with MEN (native efficient microorganism), compost without MEN and pelletized, to a sandy soil. The incubation experiment under controlled conditions (temperature and humidity for 13 weeks) was completely randomized, with 2 doses per material and 3 replicates. The soil was sampled four times along the incubation. In other experiment microbial respiration was measured, calculating cumulative C-CO<sub>2</sub> release and daily respiration rate. The organo-mineral fertilizers were obtained by Quick Wash through acidification of manure with sulfuric or oxalic acid. The liquid was separated from the solid and the P was precipitated with Ca(OH)<sub>2</sub> from the acidified liquid. Two precipitates were obtained: sulfuric acid (PPS) and oxalic acid precipitate (PPO). The by-product called washed solid was obtained from sulfuric (WSS) or oxalic acid (WSO) treatment. The composts were obtained from different treatments of poultry manure: compost (CC), compost with MEN (CMEN) and pelletized (CPE). All treatments increased CO<sub>2</sub> production compared to control. WSS and WSO showed a greater increase, while CC, CMEN and CPE showed lower respiration rates. All of materials increased the soil available P from the 15 days sampling, maintaining the increase compared to the control (12 to 41 mg P kg<sup>-1</sup>) for at least 90 days. WSS presented the smallest increases, probably because most of the P is in organic form, while CPE presented the greatest increases. The results suggest that all the poultry manure derived amendments were effective to supply readily available P to plants. The calculated P efficiency rates were in a narrow range in all materials, excepting WSS.

### PHOSPHORUS USE AND BALANCE IN FIELD CROPS OF ARGENTINA

F.O. GARCIA<sup>1</sup>, M.F. GONZALEZ SANJUAN<sup>2</sup>, E. CIARLO<sup>2,3</sup>, N.I. REUSSI CALVO<sup>4</sup>

<sup>1</sup> Consultant, Balcarce, ARGENTINA

<sup>2</sup> Fertilizar AC, Buenos Aires, ARGENTINA

<sup>3</sup> Faculty of Agronomy (UBA), Buenos Aires, ARGENTINA

<sup>4</sup> CONICET-FCA (UNMDP), Balcarce, ARGENTINA

Argentina is a world leading producer of field crops ranking sixth as cereals producer and fourth as oilseed crop producer. Main field crops are soybean, maize, wheat, sunflower, sorghum, and barley. Grain production progressively increased in the last 30 years. The six main crops yearly averaged an area of 18 million ha and a production of 40 million t in the period 1993-1995 and boosted to 37 million ha and 137 million t in the period 2019-2021. The Pampas and Chaco regions encompass most of the area under field crop production. Originally, soils of these regions presented sufficient phosphorus (P) levels, and P deficient soils were circumscribed to the eastern and southeastern areas.

Fertilizer use has been low through mid 1990's, but it increased steadily since then; it averaged 577 thousand t fertilizer product per year in the 1993-1995 period augmenting to 5.2 million t per year in the 2019-2021 period. Annual consumption of P fertilizers increased from 43.5 thousand t P in 1993-95 to 378.3 thousand t P in 2019-21. Sources other than fertilizers are scarcely use in Argentina.

Partial P balances (PPB, removal/application ratio) for field crops went from 4.9 in 1993-1995 to 1.3 in 2019-21. Analysis of P use by the three main field crops in the last twelve years (2010-2021) shows PPB close to neutral values in wheat (0.8-1.0) and maize (1.1-1.5), but still negative in soybean (1.4-2.2). Partial P productivity was of 229-283, 424-567, and 309-477 kg grain per kg applied P for wheat, maize, and soybean, respectively.

As result of negative P balances, recent soil surveys have shown sharp decreases in soil extractable P levels in most of the Pampas and Chaco regions. P balances should be improved through increased use of P fertilizers, manure, and/or other sources, especially in cropping systems dominated by soybean which is the crop that usually receives the lowest P fertilizer rates and shows the most negative P balances.

**EFFECTIVENESS OF TREATING MANURE WITH ALUM, GYPSUM, AND EPSOM SALT TO REDUCE PHOSPHORUS LOSSES UNDER SIMULATED SNOWMELT FLOODING.**

S. INDRARATNE<sup>1</sup>, I. AMARAKOON<sup>2</sup>, M. ADELEKUN<sup>1</sup>, D. KUMARAGAMAGE<sup>1</sup>, N. CASSON<sup>3</sup>, D. GOLTZ<sup>4</sup>

<sup>1</sup> The University of Winnipeg, Department of Environmental Studies and Sciences, Winnipeg, CANADA

<sup>2</sup> University of Manitoba, Department of Soil Science, Winnipeg, CANADA

<sup>3</sup> The University of Winnipeg, Department of Geography, Winnipeg, CANADA

<sup>4</sup> The University of Winnipeg, Department of Chemistry, Winnipeg, CANADA

The recurrent use of animal manure on land has raised environmental alarms, especially with the increased concentration of animal production. Phosphorus (P) losses from lands during the snowmelt period contribute to water quality parameters. The impact of treating liquid swine manure with P-sorbing chemicals to mitigate P losses has not been thoroughly explored. This research investigated the effect of manure treatments on the release of P from soil under spring snowmelt conditions. An incubation study used intact soil columns collected from a high-P (100 mg kg<sup>-1</sup>) and a low-P (6.4 mg kg<sup>-1</sup>) soil. Liquid manure was treated with alum, gypsum, or Epsom-salt and was added to intact soil columns. Treated- and untreated-manure-added soil columns were incubated for eight weeks at cool temperatures. Dissolved reactive P (DRP) concentrations in pore water and floodwater were measured weekly. At the end of the incubations, P fractions were measured after being sequentially separated. In low-P soil, the pore water DRP was 32 to 82% lower with the application of alum-treated manure than the untreated manure. The high-P soil had higher pore water DRP concentrations in all treatments than the low-P soils, with no significant differences among treatments. Surface water DRP concentrations were higher than pore water in all treatments in both soils. In both soils, significantly lower DRP concentrations in surface water were observed with the application of alum-treated manure (25 – 45%), compared to untreated manure. Analysis of the speciation of P in the soil after incubation revealed no significant differences among treatments in the low-P soil. However, in the high-P soil, lower levels of labile P species and higher levels of non-labile P species were observed in the alum-treated manure compared to untreated manure. Treating manure with alum before applying to agricultural soils significantly reduced DRP mobility to surface water, in both low-P and high-P soils and increased the non-labile species in high-P soil.

### INTRICATE INFLUENCES OF LONG-TERM BIOCHAR ON THE PHOSPHORUS TRANSFORMATION ASSOCIATED WITH IRON AND SULFUR IN RHIZOSPHERE

S. WANG, Y. WANG

Institute of Soil Science, Chinese Academy of Sciences, Nanjing, CHINA

The effects of long-term biochar application on soil phosphorus (P) diffusion, resupply process, the flux across the root-soil interface and its availability in the rhizosphere of rice (*Oryza sativa* L) remain unclear. We used high-resolution dialysis (HR-Peeper), diffusive gradients in thin films (DGT), laser ablation-inductively coupled plasma mass spectrometry, and planar optode sensor techniques to characterize, in-situ, the 1D and 2D heterogeneity and dynamics of rhizosphere soil P, iron (Fe), sulfur (S), dissolved oxygen and pH in a paddy soil, after 10 years of biochar application. Both the field and greenhouse pot experiments demonstrated that biochar addition notably decreased the soluble/labile P and Fe concentrations in rice rhizosphere (vs. no biochar addition; CK) based on the results of Peeper, DGT, and two-dimensional imaging of labile P fluxes. Furthermore, DGT-induced fluxes in the soil/sediment (DIFS) model and sediment P release risk index (SPRRI) further indicated that biochar addition decreased the diffusion and resupply capacity of P from soil solid to the solution, thereby decreasing the P release risk to the environment. This decrease under biochar treatments via changed redox status of Fe and S caused by the lower dissolved oxygen in rhizosphere soil, and increased soil pH induced precipitating of soluble inorganic P into insoluble P forms, such as calcium-bound and residual P that are unavailable for crop uptake. The in-situ study on the biogeochemical reactions of P in the rice rhizosphere may provide a new and direct perspective to better evaluate the biochar addition and potential benefits to agricultural soils.

## 4. Soil health in achieving the Sustainable Development Goals 4.03 125012 - Matching food security and environmental goals: phosphorus, a key global element

### CONTRIBUTION OF FOREST PLANTATIONS TO SOIL PHOSPHORUS RESERVES

A.P. GIANNINI<sup>1</sup>, S. RESTOVICH<sup>1</sup>, A. LUPI<sup>2</sup>, P. FERRERE<sup>3</sup>, M.J. BERIBE<sup>1</sup>

<sup>1</sup> Estación Experimental Agropecuaria INTA (Instituto Nacional de Tecnología Agropecuaria), Pergamino, Buenos Aires, ARGENTINA

<sup>2</sup> Instituto de Suelos, CIRN, INTA, Castelar, Buenos Aires, ARGENTINA

<sup>3</sup> Agencia de Extensión Rural, INTA, 9 de Julio, Buenos Aires, ARGENTINA

Forest plantations represent a productive alternative in Argentinian Pampas region and little is known about how their use impacts on phosphorus (P) cycle in long-term. In this context, understand how these plantations regulate the functions of the ecosystem and in particular their impact on soil total P (TP) reserves is essential to maintain soil productive capacity, make sustainable use at scale of stand or basin and contribute to mitigate climate change. Understanding the mechanisms underlying P availability is important to predict forest productivity in a changing environment, particularly with agricultural history. The aim was to evaluate the TP reserves in poplar plantations (*Populus* spp) with different ages and in a continuous agriculture system with more than 40 years. The study was carried out in the Pampas region, Argentina, through a completely randomized design with 3 repetitions on an entic Hapludol soil from the Saforcada series. Treatments were: 1) Poplar stand 1: 9-year-old plantation; 2) Poplar stand 2: 19-year-old plantation and 3) an agricultural site. Soil samples were obtained, from which the concentration of TP and bulk density (DAP) were measured. Since DAP showed differences between treatments, we calculated TP values at same soil mass. The TP mean reserves at 0-100 cm were  $1714 \pm 89$  ppm,  $2370 \pm 105$  ppm and  $2318 \pm 152$  ppm for agricultural site, poplar stand 1 and poplar stand 2, respectively. The forest plantation increased TP reserves by 39.6 and 42%, after 9 and 19 years of plantation, respectively, compared with agriculture site (Kruskal-Wallis test;  $p < 0.07$ ). We hypothesize that this increase was due to the absence of grain extraction and the mitigation of runoff losses. Plantation of fast-growing forest species produced significant changes in TP reserves, presenting a greater content of TP under poplar plantation in comparison with agriculture. Forest plantations represent an alternative productive which reduce nutrients exports and support the input of organic matter into the soil, contributing to the sustainability of agroecosystems.

<sup>3</sup> Faculty of Land and Food Systems, The University of British Columbia, Vancouver, CANADA

<sup>4</sup> Faculty of Land and Food Systems, The University of British Columbia, Vancouver, CANADA

Phosphorus (P) loss from agricultural land through runoff is a major risk to the environment, which can result in eutrophication and water quality degradation. The objectives of our study were to: (1) identify environmental P risk classes using critical thresholds for P saturation index (PSI) and water extractable P (Pw); and (2) evaluate the identified environmental P risk classes against the agronomic performance of silage corn. We used 424 composite soil samples collected between 2018 and 2021 in corn fields with contrasting soil properties within the Fraser Valley, Canada. Environmental critical values of 10.8% for PSI and 4.1 mg/kg for Pw were established, and four environmental P risk classes namely low, moderate, high, and very high risk classes were defined. Soils in the low risk class (PSI = 0-6.6%, Pw = 0-2.2 mg/kg) showed the least risk of P loss but had the lowest corn dry matter (DM) yield = 13.7 mg/ha, far below the provincial optimum. In the high (PSI = 10.8-24.3%; Pw = 4.1-10.3 mg/kg) and very high (PSI > 24.3% and Pw > 10.3 mg/kg) risk classes, soils had excessive P concentrations, but corn DM yield did not increase. However, our results showed that soils in the moderate risk class (PSI = 6.6-10.8%, Pw = 2.2-4.1 mg/kg) have adequate soil P to optimize corn DM yield with minimal risk of P loss to the environment. Using PSI as an indicator of environmental risk, this work provides a robust and integrated criterion to monitor and assess P risk in silage corn systems in the Fraser Valley.

**Keywords:** critical P saturation index, optimum silage corn yield, P loss, water extractable P

### CABINDA PHOSPHATE ROCK AS AN EFFECTIVE SOURCE OF PHOSPHORUS TO IMPROVE YIELDS IN ANGOLA AND SURROUNDING COUNTRIES IN AFRICA

L.I. PROCHNOW<sup>1</sup>, M. MARTINS<sup>2</sup>, R. NEWBOLD<sup>3</sup>, L. REED<sup>4</sup>

<sup>1</sup> Plant Nutrition Science & Technology, Piracicaba, BRAZIL

<sup>2</sup> Agronomic Institute of Angola, Huambo, ANGOLA

<sup>3</sup> Minbos, Soul Rock, Barcelone, SPAIN

<sup>4</sup> Minbos, Soul Rock, Perth, AUSTRALIA

Minbos is a company developing the Cabinda Phosphate Rock (PR) from Angola and will soon start producing Prosper Primeiro (Trademarks of Minbos), a natural phosphate rock (PR) that will be the first fertilizer to be produced in the country. Since 2017 the company funded agronomic research at various levels (laboratory, greenhouse and field trials) through IFDC-USA, NPCT-Brazil and IIA-Angola. The field experiment outlines were designed to compare sources of P and the control with no P added at regular rates of P<sub>2</sub>O<sub>5</sub> applied in Angola. The sources tested are a standard water-soluble P (WSP) source, MAP or TSP, the PR and the PR with additional low rates of WSP. On average, the results of all trials show that the PR per se substantially increased the yields of all crops by at least 80% and presented a RAE in average of 85% (65% to 100%). When applied with additional low rates of WSP the yields were the same to the WSP source by itself. The effectiveness of a PR varies with several factors, the most positive being PR high reactivity, soil pH < 5.6, crops > two months and rainfall > 500 mm/year. The Cabinda PR has medium to high reactivity and the conditions in most of Angola are suitable for its use. Also, good quality PR can with time present higher residual effect as related to WSP sources. Angola currently uses very low amounts of fertilizer (about 120.000 tons), all imported at high cost, and the crop yields are in average very low. Besides producing the Cabinda PR in Angola Minbos will import fertilizers and produce different blends. Based on the agronomic results so far the vision is that smallholder farmers (Grow to Eat) will use only the Cabinda PR as a source of P, while more technical farmers (Grow to Sell and Grow to Export) will be using this PR plus small additional rates of WSP.

### SYNERGISTIC EFFECT OF RICE MILL WASTE AND POULTRY DROPPING ON SOIL PROPERTIES, DEGRADATION OF HEAVY METALS AND GROWTH OF ONIONS (*ALLIUM CEPA*)

M. ANIKWE<sup>1</sup>, E. ONYEFULUCHI<sup>1</sup>

<sup>1</sup> Enugu State University of Science and Technology, Department of Agronomy and Ecological Management, Enugu, NIGERIA

<sup>2</sup> Enugu State University of Science and Technology, Department of Agronomy and Ecological Management, Enugu, NIGERIA

A two-year greenhouse study investigated the combined effect of rice mill waste and poultry droppings on sandy loam soil properties, heavy metal content, and onion growth. Different application rates of rice mill waste (15, 25, 35, and 45 tons/ha) and a fixed rate of poultry droppings (10 tons/ha) were tested in an RCBD design with four blocks. The soil was analyzed for pH, organic carbon (SOC), nitrogen (N), available phosphorus (Av. P), and heavy metal content (Al, Fe, B, and Zn) at the start and end of the experiment. The highest application rate (45 tons/ha) increased the average soil pH from 5.13 (control) to 5.55. In both seasons, SOC content ranged from 0.75% (control) to 1.41% (45 tons/ha). Total N in the soil ranged from 0.19% (control) to 0.69% (45 tons/ha). The control plots had 4.71 Cmol/kg soil Av. P, whereas the 45 tons/ha rate had 5.78 Cmol/kg. The 45 tons/ha treatment reduced ( $P=0.05$ ) soil heavy metal content compared to the control by 65% (Al), 79% (Fe), 94% (B), and 58% (Zn) in both growing seasons. The 45 tons/ha treatment resulted in the highest onion plant height (75.7 cm) and the heaviest onion bulbs (69.6 g - 98 g) compared to the control (57.1 g - 57.6 g). The study suggests that applying rice mill waste and poultry droppings can enhance soil fertility, health, and productivity, improving plant growth and yield.

### THE EFFECT EVALUATION OF COMPOST SURFACE APPLICATION AS MULCH ON THE SOIL PROPERTIES

B. BADALÍKOVÁ<sup>1</sup>, J. PRUDIL<sup>1,2</sup>, J. LANG<sup>1</sup>, P. BURG<sup>3</sup>

<sup>1</sup> Agricultural Research, Ltd., Troubsko, CZECH REPUBLIC

<sup>2</sup> Mendel University in Brno, Faculty of AgriSciences, Brno, CZECH REPUBLIC

<sup>3</sup> Mendel University in Brno, Faculty of Horticulture, Lednice, CZECH REPUBLIC

The application of organic mulching materials is a sustainable agricultural practice with significant potential. Utilizing compost as a surface mulch can enhance soil water management, alleviate water stress in cultivated plants, suppress weed growth, reduce soil erosion, preserve soil moisture, and regulate temperature. In this study, conducted at two distinct locations (A and B) with varying growing conditions, the impact of compost applied as surface mulch on soil properties was evaluated.

Both locations featured cambium modal eubasic soil, skeletal less, with up to 25% skeleton admixture, and a depth ranging from deep to medium-deep (up to 0.30 m). Site A was a plain area, while site B had sloping terrain with a 5–7° slope, making it susceptible to erosion. Compost was applied annually at location A, post-harvest, at a rate of 30 t.ha<sup>-1</sup>. At location B, compost was applied as a surface mulch without incorporation in February, on frozen soil, at a one-time rate of 200 t.ha<sup>-1</sup>. Stable, mature compost with specified parameters was uniformly applied across the fertilized plot. Crops at location A followed prescribed sowing procedures, while only maize was cultivated at location B. The experiment compared two variants: a control variant (without compost) and variant 2 with compost application.

Results indicated positive impacts of compost surface application on soil consolidation, structure, and moisture at both locations. Location B exhibited favorable effects in terms of water erosion. However, the compost application showed a partially negative impact on soil compaction in the second year at both sites. Chemical properties showed a noticeable difference only in the HA/FA ratio, which was lower in variant 2 with compost at both locations. Overall, this study highlights the potential benefits and some challenges associated with the application of compost as a surface mulch in different agricultural settings.

**DIGESTATE AND MANURE APPLICATION IN THE KOHLRABI PRODUCTION: THE EFFECTS ON TOTAL AND MINERAL N, TOTAL AND HOT WATER-EXTRACTABLE C CONTENT IN SOIL**

D. KOVACEVIC, M. MANOJLOVIC, R. CABILOVSKI, K. PETKOVIC, M. STRBAC, M. VIJUK

University of Novi Sad Faculty of Agriculture, Dositeja Obradovica 8 square, NOVI SAD, SERBIA

Digestate is the residues of the anaerobic decomposition of organic materials from biogas plants. In Serbia, there are ~30 biogas plants, and it is necessary to find their application. The content of organic matter in soil decreases, due to insufficient application of organic fertilizers. Our previous research showed positive effect of digestates on the yield of kohlrabi, and with application equal to 100 kg N ha<sup>-1</sup>, the permitted amounts of PTEs according to Serbian regulations, was not overloaded. This research aimed to examine the effect of digestate and manure application on total and mineral N, total and hot water-extractable C (HWEC) content in the soil after kohlrabi harvest.

The experiment was conducted during three growing seasons (2019-2020) on the fields in the vicinity of Novi Sad, Serbia. The experiment was set up as randomized block design. The treatments were: Control – without fertilization (Ø); Solid digestate – 100 kg N ha<sup>-1</sup> (SD1) and 200 kg N ha<sup>-1</sup> (SD2); Liquid digestate – 100 kg N ha<sup>-1</sup> (LD1) and 200 kg N ha<sup>-1</sup> (LD2); Manure – 100 kg N ha<sup>-1</sup> (M1) and 200 kg N ha<sup>-1</sup> (M2); Standard fertilization (NPK) was 100 kg N ha<sup>-1</sup>, 80 kg P<sub>2</sub>O<sub>5</sub> and 100 kg K<sub>2</sub>O.

Total N was increased with the application of M2, M1, LD2 and NPK treatment compared to control. Application of NPK, LD2, LD1, M2, and M1 treatments increased mineral N (NH<sub>4</sub>+NO<sub>3</sub>) compared to the control. The growing season was a significant factor affecting the NH<sub>4</sub>-N in the soil, while the NO<sub>3</sub>-N was affected by both fertilization and the growing season. Compared to the control, the HWEC in the soil was increased with the application of SD2, SD1 and LD2. The results indicate that the application of liquid digestate can increase total and mineral N in the soil more than solid digestate. In addition, the application of organic fertilizers increased the HWEC in the soil, suggesting that they are easily degradable.

### COMPARATIVE EVALUATION OF THE PROPERTIES OF SOIL ORGANIC AMENDMENTS PRODUCED FROM BIOWASTE RECYCLING

D. VONA, N. COLATORTI, E. LOFFREDO

Università degli Studi di Bari Aldo Moro - Dipartimento di Scienze del Suolo, della Pianta e degli Alimenti, Bari, ITALY

Intensive agriculture and invasive cultivation practices contribute to the progressive decline of the organic reserve of the soil. To address this issue and the related widespread soil pollution, the use as soil amendments of C-rich products and byproducts of technological treatments of biowaste can represent a sustainable solution. In addition to improving overall soil fertility, these materials significantly enhance the efficiency of the soil in retaining pollutants, thus limiting their leaching and the contamination of the food chain. This study, as part of a PRIN 2022 PNRR Project (P20223YAYP) funded by NextGeneration-EU M4C2, is focused on the characterization of some organic materials obtained from both processed and untreated agri-food waste, such as a solid digestate (DG) from mixed feedstock, DG-derived compost (CP) and vermicompost (VC), a wood biochar (BC) from forest trees, ground olive stones (OS) and pistachio shells (PS). Basic characterization evidenced the alkaline reaction of DG, CP, VC and, especially, BC and the acidic nature of OS and PS, while the highest EC values were measured for DG and PS. Attenuated total reflectance Fourier transform infrared (FTIR-ATR) spectroscopy together with Raman spectroscopy were used to investigate functional groups of the raw and processed materials, aiming to: i) identify the main biomolecular classes (featured lignin and lignocellulosic functional groups, hybrid inorganic clays and moieties and complex polysaccharide bulk); and ii) detect the chemical maturation state after treatments. These preliminary investigations pave the way for a pure and concrete perspective of nature-based and low-cost solutions, so all materials studied can be in principle useful tools for soil pollution control.

### PYROLYSIS OF TUNISIAN PINEWOOD INTO SUSTAINABLE BIOMATERIALS AND ITS PERFORMANCE IN CALCAREOUS SOIL

A. MAAOUI <sup>1</sup>, R. CHAGTMI <sup>1</sup>, R. KHIARI <sup>2</sup>, H. ZEMNI <sup>2</sup>, A. BEN HASSEN TRABELSI <sup>1</sup>

<sup>1</sup> Research and Technology Centre of Energy- Technopark Borj-Cédria- Tunisia, Hammam-Lif, TUNISIA

<sup>2</sup> Laboratory of Molecular Physiology of Plants- Center of Biotechnology of Borj Cedria (CBBC)- Tunisia, Hammam-Lif, TUNISIA

Agroforest biomass is an abundant, renewable and ecofriendly source for chemicals and energy production. Pinewood (PW) is seen as potential forest biomass generated annually with a great quantity in the Mediterranean region and in particular in Tunisia. This study aims to evaluate the Tunisian PW potential for conversion into solid biochar through slow pyrolysis and its effect on some calcareous soil properties. The PW and their obtained biochar were characterized in terms of proximate and ultimate analyses, thermogravimetric behavior, FTIR spectroscopy, X-ray diffraction, pH, Electrical Conductivity (EC) and surface morphology. Then, the pyrolysis runs were performed in a laboratory scale fixed-bed batch pyrolyzer at 500°C as final pyrolysis temperature, 10°C/min as heating rate, 1h (PW500-1) and 2h (PW500-2) as residence time. A three months pot experiments in a greenhouse using the produced biochars (PW500-1 and PW500-2) were conducted at the rates of 0, 2 and 4g/Kg soil.

The obtained results showed that the biochar generated have a high Carbon content (~80 wt%) and surface area (323 m<sup>2</sup>/g). The addition of carbon-rich biochars increased the total Organic Carbon (TOC), total nitrogen (TN), pH and EC values. However, there was a decrease in C/N ratios indicating the acceleration of mineralization of the treated soil. The variation in soil properties increased with increasing biochar application rates.

The findings reveal the potential of PW as biomass for biochar production with high quality through pyrolysis, as well as the performance of its application as an amendment to agricultural calcareous soil.

<sup>3</sup> Department of Chemistry, Biology and Biotechnology, University of Perugia, Perugia, ITALY

<sup>4</sup> Department of Pharmaceutical Sciences, University of Perugia, Perugia, ITALY

Biorefinery is defined as the sustainable transformation of biomass in bioenergy and bio-based products, such as biostimulants and biofertilizers, bio-polymers and bioactive molecules. The olive oil mill by-products represent a significant fraction of agro-industrial waste and can be valorized through a biorefinery approach, which aligns with ecological transition and circular economy.

The study addressed the anaerobic treatment of different residual biomass from the olive-oil chain: olive pomace (OP), olive mill wastewaters (OMWW), OP after the recovery of nanoscaled lignin and protein hydrolysates, and OMWW after the extraction of bioactive molecules. A digestate from the anaerobic treatment of livestock and agro-industrial by-products was used as inoculum (control). The mixtures used in the experimentation consisted of 75% of inoculum and 25% of each previously mentioned biomass. A batch experiment was carried out in 50 mL bioreactors under mesophilic conditions (37 °C) and monitored for 30 days. Biogas production was assessed volumetrically and cylindrical bottles were used as gasometers. Results indicated that treated OP and treated OMWW did not negatively affect the biogas production compared to the control and the raw olive oil mill by-products (OP and OMWW) during the batch test. These findings underscore the potential of the biorefinery system for the final disposal of olive oil mill waste materials to recover valuable substances and renewable energy generation. Ongoing studies are evaluating the agricultural quality of the residual digestates, before and after their co-composting.

In conclusion, biorefinery serves as a cutting-edge approach to repurpose these by-products, reducing their volume, meanwhile generating high-value-added products that can be reused as biofertilizers.

## 4. Soil health in achieving the Sustainable Development Goals 4.04 131145 - Dynamics and functions of soil organic matter under new and traditional amendments

### IMPROVING BIOCHAR AMENDMENTS DERIVED FROM FIBER SLUDGE BY LOADING NITROGEN SOURCED FROM LIQUID ORGANIC FERTILIZERS

V. HETMANENKO, J. NIKAMA

Natural Resources Institute Finland - Departments: Bioeconomy and environment; Natural resources, HELSINKI, FINLAND

Nutrient surpluses in combination with fertilizer-related emissions and maintenance of soil organic matter levels have brought enhanced efficiency fertilizers (EEFs) to the forefront of modern agriculture. Fiber sludge (pulp and paper mill sludge) has great prospects of becoming a matrix for EEFs production due to its strong sorption power, especially after pyrolysis, and considering the high content of organic carbon and lime in it. Physisorption analysis of the biochars derived from fiber sludge showed a higher surface specific area ( $m^2/g$ ) of low-nutrient fiber compared to raw mixed sludge. Mass losses of mixed sludge during slow pyrolysis at 450–550 C were two times lower than the low-nutrient fiber.

N-loading experiment with liquid side streams (pig slurry, tannery wastewater, and biogas effluent) at the char:solution ratio 1:10 and original pH proved the dependence of  $NH_4^+$  adsorption by chars on the particle size distribution within the applied range (0.25–1 mm). The highest  $NH_4-N$  content was found in particles  $<0.25$  mm in solutions char : tannery wastewater corresponding initial content in liquid side streams. Biochar derived from low-nutrient fiber exhibited the highest N adsorption capacity with  $NH_4-N$  content of  $2.62 \pm 0.30$  % in the dry sample.

Carbon content in N-enriched biochars produced varied from  $41.3 \pm 8.7$  % in mixed sludge to  $72.8 \pm 6.5$  % in low-nutrient fiber.

Clay-textured soil was incubated with N-enriched biochars at an application rate of 5 t ha<sup>-1</sup> with the following rain simulation which represents typical rains in Finland. Amending soil with N-enriched biochars resulted in higher soil pH values. The mobilization and transport of soil particles can have negative agronomic and environmental effects. In laboratory experiment, we observed decreased turbidity in percolated water from biochar-amended soil sourced from fiber sludge compared to untreated soil. The addition of recalcitrant carbon introduced with biochar application would also be beneficial considering the carbon sequestration.

Soil health is a major issue for crops and human health, as it supports plant and animal productivity and maintains ecosystem quality. In recent decades, the use of green cover in fruit orchards has gained importance. The objective of the use of green covers is to maintain and improve soil quality. These covers can increase organic matter and nutrient content, reduce erosion, contribute to balance the water balance, hydrological cycle and even soil biodiversity. Therefore, this work was focused on evaluating the effect on the soil of the use of cover crops based on grasses, legumes, crucifers, and a mixture of various flowering species in soils dedicated to the cultivation of persimmon (*Diospyros kaki*, Thumb) in the Ribera Alta Valenciana (East Spain). In total, ten orchards were studied: two sown with the different plant covers, five with spontaneous covers and three without covers in which an herbicide treatment was carried out for weed control. Soil samples were obtained by systematic sampling at a total of 71 sites within 15 cm depth. Soil respiration was measured in the field and pH, electrical conductivity, organic carbon, organic matter (SOM), and enzyme activities (EA), as well biomass carbon (BC) were determined in the laboratory. Preliminary results showed that some of the cover crops such as legume mixture, flower mixture and spontaneous cover increased SOM, respiration, BC, and some AE values (ex. hydrolases). In the conditions of our experiment the use of cover crops is a recommended practice to improve soil quality in persimmon cultivation.

<sup>2</sup> Department of Geology, Kangwon National University, Chuncheon, SOUTH KOREA

Biochar is an efficient method for carbon neutrality and is recognized as one of the negative emissions technologies proposed by the IPCC. It is known that treating biochar on agricultural land can improve crop yields, improve soil properties, reduce salt accumulation, and reduce greenhouse gas emission. Many countries, including South Korea, are making efforts to achieve carbon neutrality through the utilization of biochar. In South Korea, the main sources of biochar are wood pellets and rice husks, and various initiatives are underway to utilize livestock manure, given the continuous increase in its production. However, there is still a lack of prior research on the types of biochar and the utilization rate of biochar by cultivated crops. In this study, pot experiments were conducted to determine the optimal application rates for cabbage and radish using three types of biochar. The application rates were set at 1 t/ha, 2 t/ha, 4 t/ha, and 8 t/ha, and two different soils with varying levels of organic matter content (25.5 g/kg, 8.5 g/kg) were used. There was no significant difference in yield changes of radish and cabbage according to biochar treatment up to the 4t/ha treatment group. However, from 8 t/ha, there was a decrease in yield due to biochar treatment, which is believed to be because a large amount of biochar inhibited the movement of nutrients in the soil. Soil properties such as pH, OM, and CEC increased with biochar treatment increased. Through this study, it has been confirmed that adhering to the appropriate biochar application rates can be a crucial consideration for enhancing crop productivity, improving soil characteristics, and promoting sustainable agriculture. Therefore, it is suggested that future research should involve long-term field experiments to monitor changes in soil properties and crop productivity.

### THE INFLUENCE OF LONG-TERM USE OF RYE AND CORN MONOCULTURES AND DIFFERENT FERTILIZATION ON THE SPECTROSCOPIC PROPERTIES OF SOIL ORGANIC MATTER

L MIELNIK<sup>1</sup>, J WEBER<sup>2</sup>, V BOGUZAS<sup>3</sup>, M PODLASINSKI<sup>1</sup>, A KOCOWICZ<sup>2</sup>

<sup>1</sup> West Pomeranian University of Technology in Szczecin, Szczecin, POLAND

<sup>2</sup> Wrocław University of Environmental and Life Sciences, Wrocław, POLAND

<sup>3</sup> Vytautas Magnus University Agriculture Academy, Kaunas, LITHUANIA

The aim of the investigation was to determine the influence of different soil management on the properties of humin – the most stable fraction of soil organic matter.

The research deal with loam cambisol located at the long-term field experiment established in 1967 on the Norekiskes plots of the Experimental Station of the Vytautas Magnus University, Agriculture Academy, Kaunas, Lithuania. The experiment included plots with two cultivation variants: rye monoculture and corn monoculture. Three fertilization variants were used for each crop: no fertilization (control), NPK fertilization, NPK fertilization with manure and legumes (NPK\_MAN\_LEG). Soil samples were collected from A horizon and examined for soil texture, total organic carbon (TOC), and total nitrogen (TN). The obtained results indicate that 54-year use of manure with legumes under corn monoculture resulted in an increase in TOC by 70% and TN by 48%. In the case of rye monoculture, no significant changes in TOC content were observed, while NPK-MAN\_LEG fertilization resulted in a slight increase in TN.

Humin was obtained after discarding humic and fulvic acid, and digesting the mineral fraction in an HF-HCl mixture. The obtained humin was purified by dialysis, and then freeze-dried. To analyse the optical properties absorption spectra in the UV-Vis range and fluorescence spectra (synchronously scanned SSF and three-dimensional EEM matrix spectra) were recorded.

Comparing with results of our other investigation, the studied humin indicated relatively lower complexity of the molecular structure and a more aliphatic character. Their structure also showed specific aromatic systems with a not very extensive network of conjugated bonds. The NPK in both crops resulted in an increase in absorbance in the short-wave part of the absorption spectra, while the NPK\_MAN\_LEG resulted in a decrease in absorbance compared to the control. In the case of fluorescence spectra, an opposite tendency of changes in its intensity was observed.

The research was financed by EJP SOIL program, NCBR project EJPSOIL/I/78/SOMPACS/2022.

**FOSTERING SOIL ORGANIC MATTER DYNAMICS AND PLANT GROWTH: A COMPREHENSIVE STUDY ON THE SOIL ORGANIC AMENDMENT POTENTIAL OF PÁLINKA SPENT WASH THROUGH COMPOSTING**

L.R. BORGES SILVA, L. KARDOS

Hungarian University of Agriculture and Life Sciences, GÖDÖLLO, HUNGARY

The Pálinka distillery industry in Hungary generates significant organic waste, particularly 'spent wash' also called 'mash'. This post-distillation residue poses environmental challenges due to its high organic load, low pH, and recalcitrant compounds. This research addresses the need for a sustainable solution by focusing on composting to transform Pálinka spent wash into stable organic matter and neutralize phytotoxic substances. The study targets initial challenges—acidic pH, high moisture content, and elevated copper levels—through aerobic composting. In a lab-scale experiment, the spent wash was composted with wood chips and additives like diatomaceous earth, wood ash, vinasse, coconut fiber, andesite, calcium sulfate, ready-manure compost, and carbon. Two breathable drum composters were used, one with mash mixed solely with wood chips and the other combining wood chips with finished cow manure compost as an inoculum. Comprehensive analyses, including germination and enzyme activity tests, confirmed the unsuitability of the Pálinka mash for plant growth without being composted. Evaluating the ready-mash compost using various plants demonstrated its potential to enhance soil organic matter (SOM) levels, promote nutrient cycling, and improve soil structure. The study also addressed environmental risk factors, emphasizing composting's role in food safety. High copper levels in Pálinka spent wash were effectively reduced through composting, especially with ready-manure compost and diatomaceous earth. Wood ash, diatomaceous earth, and ready-manure compost emerged as effective treatments, showcasing nutrient supply and water retention. Stable organic matter formation, crucial for soil fertility, increased significantly, especially with ready-manure compost. Pálinka spent wash compost plays a pivotal role in nutrient cycling, converting organic nutrients into plant-available forms. Enhanced SOM positively impacts soil health, promoting efficient nutrient uptake and sustainable soil management. This research underscores the urgent need to address environmental and health risks associated with Pálinka spent wash, highlighting its untapped potential as a soil amendment for sustainable agriculture. Composting offers an innovative waste management approach for traditional industries, contributing to environmental protection and supporting sustainable agricultural practices.

**ASSESSING THE IMPACT OF SUSTAINABLE LAND MANAGEMENT ON MITIGATING DESERTIFICATION AND IMPROVING SOIL PROPERTIES IN MEDITERRANEAN SEMI-ARID ECOSYSTEMS: A CASE STUDY FROM SOUTHERN PORTUGAL**

H.K. ISHAQ, E. GRILLI, M. MASTROCICCO, R. MARZAIOLI, F.A. RUTIGLIANO, S. CASTALDI

DISTABIF, University of Campania Luigi Vanvitelli, Caserta, ITALY

The European Mediterranean region currently faces a significant risk of desertification, mainly due to unsustainable land management practices and accelerating climate risks. This study, integral to the LIFE16 CCA/IT/000011 Desert Adapt project, seeks to assess the ability of a Sustainable Land Management (SLM) approach, employing adaptation measures and nature-based solutions to improve ecosystem services. The specific focus is on the introduction of Rotational Grazing (RG) as a sustainable approach to counteract land degradation in conventional grazing (CG) areas in southern Portugal. After five years of implementing, we conducted a follow-up comprehensive assessment of soil amelioration, comparing results with nearby conventional grazing systems. Our evaluation included physicochemical and biological properties of the soil. Notably, soil carbon (C) emerged as a pivotal variable, exhibiting significant correlations with total nitrogen (TN), cation exchange capacity (CEC), water-holding capacity (WHC), and essential biological metrics such as fungal and microbial biomass. Remarkably, RG, particularly when implemented without tillage, led to significant improvements in overall soil health. Total Organic Carbon (TOC) observed a remarkable increase of 118.9%, while TN recorded a noteworthy improvement of 119.3%. Additionally, WHC demonstrated an improvement of 27.6%, and CEC increased by 57.5%. Biological parameters also showed significant improvements, with microbial biomass increased by 44.2%, and fungal biomass by 84.7%. Beyond the soil-focused outcomes, our study unveiled broader benefits. The sustainable management practices, including RG, were found to enhance grass productivity while concurrently reducing dependence on external feed, thus promoting a more resilient and self-sustaining farming system. The findings of this study exhibit the relevance of adaptive sustainable management to enhance soil carbon and related ecosystem services and revert land degradation. Such strategies are key for the environmental, social and economic sustainability of Mediterranean areas under desertification and climatic risk.

<sup>6</sup> Agroscope, Zurich, SWITZERLAND

The loss of soil organic matter (SOM) from cropland soils hinders the provision of ecosystem services and contributes to climate change. In parallel, the nitrogen use efficiency (NUE) of fertilizers has barely improved in the last decades. Besides being a promising negative emission technology, increasing SOM in croplands is advocated as a solution to limit N losses to the environment because of its role in regulating the N cycle. Unfortunately, our ability to manage SOM remains limited by knowledge gaps about the impacts of soil input stoichiometry on microbial metabolism that, indeed, drives the C stabilization pathways in SOM. The system is further complicated by the feedbacks of the amount and quality of SOM on the same microbial processes that result in the stabilization of inputs into SOM.

The MaCaN project aims at identifying the optimum fertilization practices for croplands to increase SOM and NUE of organic and mineral fertilizers. We take advantage of a long-term field trial established since 1976 in Switzerland with several types of organic amendments (OA) and different levels of mineral N fertilization (minN). As OA have induced a gradient of SOM over the years, the specific effects of SOM content on C stabilization and NUE is addressed by implementing, in the original plots, subplots that did not receive OA. The impacts of treatments on the preferential stabilization pathways of organic matter inputs is assessed using Py-GC/MS to determine the ratio of microbial-to-plant derived SOM. The effect of SOM and minN levels on the proportion of fresh organic matter residues that have been stabilized in SOM fractions is addressed by the differences in isotopic signatures between maize biomass and the SOM. Finally, microbial processes driving the stabilization of C and N in SOM and the distribution of N among the soil-crop system will be assessed using <sup>15</sup>N-labeled mineral fertilizer. The project will highlight the interconnectedness of three functions, namely C storage, nutrient retention and food production.

### INCREASING MICROBIAL FUNCTIONAL DIVERSITY AND ORGANIC MATTER STABILITY IN MOUNTAIN SOILS CAUSED BY TREELINE SHIFTS

S. SUSHKO<sup>1</sup>, K. IVASHCHENKO<sup>1</sup>, A. KOMAROVA<sup>1</sup>, A. YUDINA<sup>2</sup>, E. ELSUKOVA<sup>3</sup>, N. ANANYEVA<sup>1</sup>

<sup>1</sup> Institute of Physicochemical and Biological Problems in Soil Science, Pushchino, RUSSIA

<sup>2</sup> V.V. Dokuchaev Soil Science Institute, Moscow, RUSSIA

<sup>3</sup> Saint Petersburg State University, Saint Petersburg, RUSSIA

In the mountains, modern climate change is rapidly shifting the treeline on the meadows. This can affect soil microbial activity and the redistribution of soil organic matter (SOM) between its particulate (POM) and mineral-associated (MAOM) fractions. Decomposing more recalcitrant plant residues, such as forest litter, requires a wide variety of enzymes. Consequently, the treeline shifts may increase both the ability of soil microorganisms to metabolize diverse organic substrates (i.e., microbial functional diversity) and the accumulation of their degradation compounds in the MAOM fraction. To test this hypothesis, we chosen six forest-meadow ecotones on reserved and grazed slopes in the Northwest Caucasus of Russia. All slopes were of north-eastern exposure, steepness of 25-30 degrees, and had nonalkaline soil parent materials. Along each ecotone, plant material (above-ground herbaceous biomass, forest litter) and soil samples from the upper 0-10 cm layer were collected in 0.5 × 0.5 m plots in forest, treeline and meadow. Plant recalcitrance was determined by aromaticity index based on CP/MAS 13C-NMR analysis results. Microbial functional diversity was measured using the MicroResp™ technique and expressed as Shannon-Wiener index (Hclpp). MAOM was determined by wet sieving through 53 μm cells. From meadows to forests, plant residue recalcitrance increased, as evidenced by aromaticity index increasing from 0.21 to 0.25 (on average for both land uses). A similar average upward trend was found for Hclpp index (from 2.45 to 2.49) and MAOM portion (from 17% to 35%). This confirms our hypothesis that the tree expansion into meadows increases microbial functional diversity and SOM stability.

The study was supported by Russian Science Foundation 22-74-10124.

### ANTHROPOGENIC SOIL MANAGEMENT PRACTICES IN RESTORING AND MANAGING SOIL QUALITY AND CARBON SEQUESTRATION POTENTIAL

M. VILKIENE, I. MOCKEVICIENE

Lithuanian Research Centre for Agriculture and Forestry, Kedainiai dist., LITHUANIA

Anthropogenic soil management is one of the most noticeable indicators of human activities that either contribute to soil degradation or soil improvement. These problems are further compounded by intensive agricultural usage and largely attributed to soil degradation concerning a decline in soil organic content, soil erosion, water contamination, and loss of biodiversity. The selection of sustainable agricultural practices is crucial to maintaining soil qualitative parameters and optimizing carbon sequestration potential, as well as developing an effective strategy for ensuring sustainable agriculture. This study aimed to achieve the following objectives: (1) to analyze the alterations in SOC and other parameters caused by the various anthropogenic management practices in acid soil; (2) to find out whether management-induced changes are large enough to have the potential to reduce soil degradation and improve SOC sequestration and soil quality.

The study was based on comparing different chemical indicators data from 3 long-term experiments, conducted in the Western part of Lithuania. Changes in soil properties during more than 20 years (1999-2022) were identified. The most common soil management practices applied in Lithuania such as liming, manuring, residue maintenance, and tillage have been selected for analysis. Changes in soil parameters, carbon sequestration potential, mean effect size, and resistance indices were examined and compared. Considering the soil quality determinant indices, applied agricultural practices ranked as follows: manuring > residue management > reduced tillage > liming. Manuring and residue maintenance showed a greater SOC content accumulation potential with the mean effect size of 0.02 – 0.28 and the increase varied from 1.89% to 32.89%. The lowest soil resistance indices values were obtained for low level of nutrients (N and P), organic carbon, pH, and Zn, showing that these properties, compared with the others, are more sensitive to applied agricultural practices. All these findings provide information for promoting better soil management, soil protection, land use planning, and planning remedial measures, especially in the most affected areas.

**Keywords:** soil reclamation, liming, manuring, tillage, agricultural practices

### FACTORS INFLUENCING ORGANIC CARBON STOCKS IN FOREST SOILS OF THE CZECH REPUBLIC

L. BORUVKA <sup>1</sup>, V. SRAMEK <sup>2</sup>, K. NEUDERTOVA-HELLEBRANDOVA <sup>2</sup>, V. FADRHONSOVA <sup>2</sup>, L. PAVLU <sup>1</sup>, O. DRABEK <sup>1</sup>, V. TEJNECKY <sup>1</sup>, R. VASAT <sup>1</sup>, R. NOVOTNY <sup>2</sup>, E. CIENCIALA <sup>3</sup>

<sup>3</sup> IFER Institute of Forest Ecosystem Research Ltd., Jilove u Prahy, CZECH REPUBLIC

Forest soils represent a very important pool of soil organic carbon (SOC) and proper management of these soils can thus mitigate climate change. In this research, we analyzed factor influencing the SOC stocks in temperate forests at national scale of the Czech Republic. We used data from the aggregated database of forest soils of the Czech Republic, containing standardized soil properties compiled from several national-scale soil surveys done in the years 2000-2020, including results from several thousands of sampling sites. The effects of principal drivers on SOC stocks were studied separately for forest floor horizons (F+H), mineral topsoil (0-30 cm), and deeper mineral layers (30-80 cm), and for the whole soil profiles.

Tree species composition, altitude and forest vegetation zones were found to be the most important drivers of forest SOC stocks. Generally, the total carbon stocks are higher under deciduous forests than under the coniferous ones. Under coniferous forests, the contribution of forest floor (F+H) to the total SOC stock to the depth of 30 cm is higher than under broadleaved and mixed forests. Nevertheless, the mineral part of the profiles is still the most important SOC pool. Bigger accumulation of SOC in soil profiles is related to lower temperatures and higher precipitation at higher altitudes, and lower pH reducing the decomposition rate. The strongest effect of pH on SOC accumulation was found in forest floor. The high SOC stock is generally connected also with lower organic matter quality indicated by higher C/N ratio. Some differences between soil classes were also shown: the highest SOC stocks were in Podzols and Histosols, the lowest in Leptosols, Stagnosols, Technosols and Cambisols Arenic.

### REGULATING SOIL CARBON STOICHIOMETRY AND STORAGE: THE ROLE OF METAL CONTAMINATION AND CLIMATE CHANGE

C. VERGARA CID<sup>1</sup>, N. SÁNCHEZ<sup>1,2</sup>, S. DRABESCH<sup>2</sup>, E. BLAGODATSKAYA<sup>3</sup>, S. KÜMMEL<sup>4</sup>, E.M. MUEHE<sup>1,2</sup>

Soil carbon and nutrient stoichiometry are critical indicators for the quality and quantity of soil organic matter, reflecting the relationships between nutrient mineralization and immobilization. High metal inputs adversely affect soil health by impacting nutrient availability, microbial growth and activity. Future climatic conditions can enhance organic matter decomposition/mineralization rates and render nutrients and metals more mobile in soils. Consequently, the coupling of metal contamination and climate change may impact carbon dynamics more severely than either single factor. Although many studies have focused on a single factor, the study of combined factors remains underexplored. To investigate whether, to which degree and how the coupled effects of metal contamination and climate change affect carbon and nutrient cycling, we cross-factorially incubated an agricultural soil with either background or elevated heavy metals (+760 mg/kg Zn, +0.4 mg/kg Cd, and +1.5 mg/kg Pb) under today's or future climatic conditions (according to IPCC RCP 8.5: +4° C, lower soil moisture and +400 ppmv CO<sub>2</sub>). Future climatic conditions significantly increased Pb and Zn availabilities in the contaminated soil. However, the impact of climate change alone or coupled with metals on carbon cycling and stoichiometry was negligible compared to metal contamination alone. Metal inputs triggered severe stress on soil microorganisms, as observed by reduced microbial biomass, lower carbon hydrolytic enzyme activity, and a doubled metabolic quotient relative to non-metal amended soils. This indicates that microorganisms allocated more energy on maintaining to cope with metal stress rather than to growth. This higher energy demand under metal stress produced shifts in carbon stoichiometry as observed in lower C:N ratios and a strong stoichiometric imbalance for carbon and nitrogen compared to the homeostatic response in the background soil. The outcomes of this study show how an environmental stressor such as heavy metals can overcome the effects of climate change, producing a decoupling of C and N cycling. This may lead to long-term decreases in C and N storage in soils.

### BIOCONTROL POTENTIAL OF RHODOTORULA YEAST STRAINS FROM POLLUTED ENVIRONMENTS AGAINST MYCOTOXIGENIC FUNGI

V.M. CORBU<sup>1</sup>, O. CSUTAK<sup>1,2</sup>

<sup>1</sup> University of Bucharest, Faculty of Biology, Department of Genetics, Bucharest, ROMANIA

<sup>2</sup> University of Bucharest, Research Institute of the University of Bucharest (ICUB), Bucharest, ROMANIA

Agricultural crops are frequently affected by bacterial and fungi phytopathogens with negative impact on plants, animals and humans. The current antimicrobial strategies involve excessive use of chemical pesticides with low biodegradability which causes the decrease of soil quality. The antimicrobial activity of yeasts, natural competitors of phytopathogens, represents an important basis for the development of ecological antifungal products essentials for the transition to sustainable agricultural practices.

Three *Rhodotorula* strains isolated from polluted environments from Romania, *R. mucilaginosa* CMGB-G1, *R. mucilaginosa* CMGB188 and *R. glutinis* CMGB189, were tested for their ability to inhibit mycelial growth of seven fungal strains belonging to *Botrytis cinerea*, *Rhizoctonia solani*, *Aspergillus ochraceus* and *Aspergillus flavus*. The results showed that regardless of the type of culture medium used for cultivation (Sabouraud Agar, Potato Dextrose Agar and Yeast-Sucrose Agar), all yeasts reduced by up to 30% the growth of the fungal mycelium, the most sensitive strain being *A. ochraceus* for which complete inhibition of growth was observed in the presence of *R. mucilaginosa* CMGB-G1, followed by *A. flavus* strains. Among the main mechanisms of antimicrobial action described for *Rhodotorula* strains, the production of carotenoids and rhodotorulic acid stand out, and their production being influenced by the use of alternative sources of nitrogen or carbon. In order to determine the mechanism of antifungal activity, the *Rhodotorula* strains were cultivated on YPG medium, (glucose as a carbon source, peptone/ yeast extract as organic nitrogen source) and on Rhd-urea medium (sucrose as carbon source, urea as organic nitrogen source). The results revealed that for *R. glutinis* CMGB 189, the mechanism of action is based on both the synthesis of carotenoids and rhodotorulic acid, while for *R. mucilaginosa* most probably relies on carotenoid synthesis.

In conclusion, the present work allowed the characterization of three *Rhodotorula* strains with significant antifungal abilities, as promising biocontrol agents for protecting crops with minimum impact on the quality of agricultural soil.

### EFFECTS OF A MEGAFIRE ON THE ARBUSCULAR MYCORRHIZAL FUNGAL COMMUNITY AND PARAMETERS IN THE BRAZILIAN CERRADO ECOSYSTEM

J. MOURA <sup>1</sup>, L. .C. LOPES FILHO <sup>2</sup>, R. .F. SOUZA <sup>2</sup>, S. DUTRA E SILVA <sup>1</sup>

<sup>1</sup> Univ. of Goiás, Graduate Stud. in Soc., Technol. & Environ. Sci., Anapolis, BRAZIL

<sup>2</sup> Evangelical College of Goianésia, Sedmo. Soil Res. Group, Ecol. & Dynamics of Organic Matter, Goianésia, BRAZIL

The biggest fire event in the history of the Cerrado, suspected as arson, occurred in the Chapada dos Veadeiros National Park in October 10, 2017, destroying about 66,000 ha. The Chapada dos Veadeiros National Park was created in 1961 and comprises an area of 240,614 ha, and in 2001 was declared a Natural World Heritage Site by UNESCO. This study aimed to evaluate the effects of a megafire on the AMF community in Cerrado soils, by measuring parameters such as spore density, easily extractable glomalin (EEG), and the rate of successful root colonization, comparing burned and unburned areas in five commonly found phytophysiognomies in the region. Study area: Chapada dos Veadeiros National Park, Goiás, Brazil. This site suffered the biggest fire in its history on October 10, 2017, with an affected area of 66,000 ha. Materials and methods: We analyzed AMF spore density, roots' mycorrhizal colonization rate, easily extractable glomalin (EEG), as well as the AMF genera present. These parameters were evaluated in burned and unburned areas of five common hytophysiognomies of the region. Main results: Fire presence immediately affected the mycorrhizal community parameters in Cerrado soils, which tended to increase afterwards. The presence of AMF genera did not differ between burned and unburned areas, with *Acaulospora*, *Claroideglomus*, *Diversispora*, *Glomus*, *Funneliformis*, *Sclerocystis*, and *Gigaspora* being present. The recovery of AMF community conditions in the Cerrado after fire events could also be observed in the mycorrhizal parameters evaluated, as the values of spore density, roots' mycorrhizal colonization rate, and EEG were similar in the burned and unburned areas. Research highlights: AMF diversity, and especially their community parameters, show great recovery after fire events, since they are crucial in processes like nutrient cycling and soil aggregation.

Figure 1. Arbuscular mycorrhizal fungi spore density (A, D, G, J, K), roots mycorrhizal colonization (B, E, H, I, L, N), and easily extractable glomalin content (C, F, I, O) in Cerrado soils in burned and unburned plots during five sampling dates (1, 3, 5, 9 and 17 months after sampling). Small letters indicate significant differences for sites without fire; capital letters for sites with fire.

### IMPACT OF LONG-TERM FERTILIZATION ON THE DIVERSITY AND GLOMALIN PRODUCTION OF THE ARBUSCULAR MYCORRHIZAL FUNGI

T. TAKÁCS, P. JUHÁSZ, S. PABAR, A. MAKÓ, B. KELEMEN, I. CSERESNYÉS, A. FÜZY

Institute for Soil Sciences, HUN-REN Centre for Agricultural Research, Budapest, HUNGARY

Arbuscular mycorrhizal (AM) fungi are key indicators of soil health. Glomalin produced by the AMF hyphae helps the formation of soil aggregates, it improves soil structure, water-holding capacity and it is a significant part of soil organic matter.

The effect of soil management on glomalin (Easily Extracted Glomalin-Related Soil Protein; EE-GRSP) has been examined at sites of NPK fertilization [160 kg ha<sup>-1</sup> N (NH<sub>4</sub>NO<sub>3</sub>), 80 kg ha<sup>-1</sup> P (P<sub>2</sub>O<sub>5</sub>), 80 kg ha<sup>-1</sup> K (K<sub>2</sub>O)] long-term field experiment with and without farmyard manure treatments in Haplic Chernozem soil (Martonvásár; Hungary). Soil physicochemical properties were measured, the AM fungal colonization and community composition were determined.

Highly positive correlations were detected between various physicochemical soil properties (humus and nitrogen content, dissolved organic carbon and macroaggregate stability) and the EE-GRSP. The EE-GRSP was inversely related with pH. The topsoil glomalin ranged from 0.37 mg/g soil to 0.77 mg/g soil. The highest soil glomalin contents were found in the N-fertilized plots.

The rate of AMF colonization responded mainly to plant nutrition status and plant requirements and this plant-mediated effect appears to be present in the case of AMF colonization. The AMF diversity and abundance were decreased by both mineral and organic fertilization. Nitrogen trials reduced drastically the abundance of *Funneliformis mosseae*, which was a dominant indigenous AMF species in control plots. *Rhizophagus intraradices* was also abundant species in the soils, it was significantly declined by NPK trials. *Septoglomus* sp. is a good indicator species, that was eliminated by long-term N fertilization.

Agricultural land use optimization contributes to yield and soil security. The synthesis of our data could result in a land use effect assessment considering the quantity of soil glomalin. Glomalin can be a universal indicator of land use change effects on soil C and soil health.

The research was funded by the Hungarian Research Network (SA-26/2021) and the Sustainable Development and Technologies National Programme of the Hungarian Academy of Sciences (FFT NP FTA).

**MICRO-MAPPING OF BACTERIA IN AN EXTREMELY ACIDIC ENVIRONMENT BY MEANS OF THIN SECTIONS, DIFFERENT LIGHT SOURCES, AND IMAGE ANALYSIS**

M. .D.C. GUTIÉRREZ CASTORENA<sup>1</sup>, E.V. GUTIERREZ CASTORENA<sup>2</sup>, T. GONZALEZ VARGAS<sup>1</sup>, C.A. ORTIZ SOLORIO<sup>1</sup>

<sup>1</sup> Programa de Edafología, Campus Montecillo, Colegio de Postgraduados, Texcoco, MEXICO

<sup>2</sup> Facultad de Agronomía, Universidad Autónoma de Nuevo León,, Escobedo, Nuevo león, MEXICO

In environmental remediation, the application of calcium carbonate to pyrite-rich mine tailings is a common practice. However, little is known about how the process of neutralisation and soil formation occurs in situ and at the micron scale, where bacteria are thought to play a fundamental role. The aim of the present research was to map at the microscopic scale to determine the distribution and quantification of bacteria in the mine waste and in different plantations. The study was carried out in Zimapán, Hidalgo, Mexico, where the mining activity started 100 years ago, so that the tailings, with a high content of pyrite, have different degrees of alteration and extreme conditions of acidity. Some of the tailings have been under vegetation cover for 30 years with different plant species. Bulk samples (0-10 and 10-20 cm depth) for laboratory analysis and undisturbed samples for micromorphological description were collected from each plantation (rhizospheric zone) and tailings. High-resolution images (5.3, 2.6, and 0.25  $\mu\text{m}$ ) of the entire thin section were taken using different objectives (2 $\times$ , 10 $\times$ , and 20 $\times$ ) and four light sources. Brightness values (RGB) were obtained for each component: PPL (aggregates and organic matter), oblique incident OIL (pyrite and goethite crystals), XPL (CaCO<sub>3</sub> and gypsum) and fluorescence LF (bacteria), to generate thematic maps. Spatial operators were used for image analysis and map quality. The results indicate that under extremely acidic conditions and up to neutral conditions, bacteria are associated with pyrite to form biofilm-like structures. They also occur on calcite in fissures or dissolution features. The transition between oxidation and dissolution develops metastable minerals such as goethite and gypsum. The distributions and relationships of bacteria with other mine tailings components vary with their degree of alteration between minerals, aggregates, and organic matter. Thematic maps and the quantification of each of the components and bacterial colonies with sulfate-bearing minerals in the tailings mine were facilitated by the different types of light and brightness values.

### LYSIS OF SOIL MICROBIAL CELLS BY CO<sub>2</sub> OR N<sub>2</sub> HIGH PRESSURIZATION COMPARED WITH CHLOROFORM FUMIGATION

S. PALIAGA, V.A. LAUDICINA, L. BADALUCCO

Department of Agricultural, Food and Forest Sciences, University of Paler, Palermo, ITALY

The classical chloroform fumigation-incubation (CFI) and fumigation-extraction (CFE) methods are nowadays among the most used for determining soil microbial biomass, although the chloroform lysing of microbial cells is not always complete. Here, we have tested a physical method, used for sterilizing foods but never in soil, based on N<sub>2</sub> or CO<sub>2</sub> high pressurization (N<sub>2</sub>HP or CO<sub>2</sub>HP, respectively) to cause microbial cell lysis. The N<sub>2</sub>HP and CO<sub>2</sub>HP were tested on two soils differing for their organic matter content, one agricultural (AGR) and one forest (FOR), and firstly were compared with the CFI. The CO<sub>2</sub> extra-flush from both soils during 10-d incubation by N<sub>2</sub>HP was lower than that by CFI method, whereas that by CO<sub>2</sub>HP was greater. Then, the lysis by CO<sub>2</sub>HP was compared with that by the CFE method by varying CO<sub>2</sub> pressure and duration. The CO<sub>2</sub>HP, at proper conditions, was more efficient than CFE method to cause the lysis of soil microbial cells. Moreover, both CO<sub>2</sub> pressure value and duration were important in increasing the extractable organic C compared to the CFE. The most successful combination of high CO<sub>2</sub> pressure and duration was 4.13 MPa and 32 h. However, we cannot exclude that CO<sub>2</sub>HP might have caused the release of soil organic C not ascribable to living organic matter. Further studies using <sup>13</sup>C and/or <sup>15</sup>N-labeled microbial cells should assess the release of abiotic organic C.

### ACTIVITY OF THE SOIL MICROBIOME IN A HUNDRED-YEAR FERTILIZATION EXPERIMENT UNDER SPRING BARLEY OR WINTER TRITICALE IN CROP ROTATION

M. FRAC<sup>1</sup>, K. OSZUST<sup>1</sup>, E. HEWELKE<sup>2</sup>, A. PERZANOWSKA<sup>2</sup>, J. WEBER<sup>3</sup>

<sup>1</sup> Institute of Agrophysics, Polish Academy of Sciences, Lublin, POLAND

<sup>2</sup> Warsaw University of Life Sciences - SGGW, Warsaw, POLAND

<sup>3</sup> Wrocław University of Environmental and Life Sciences, Wrocław, POLAND

The research was carried out based on a field experiment established by the WULS-SGGW research station in Skierniewice (Poland, 51.965° N, 20.160° E) in 1921. The study included soil samples taken from a depth of 0-20 cm under wheat cultivated in crop rotation for 100 years. Various fertilization treatments were used within the experiment, including CaNPK mineral fertilization, CaNPK mineral fertilization used together with organic fertilization in the form of manure and the same treatments, but with the use of legumes every five years in crop rotation.

The research of soil microbiome activity included determination of soil enzymatic activity, biodiversity indicators and the metabolic profile of soil microbiota using Biolog Ecoplates.

As a result of the conducted research, significant differences were observed in the activities of beta-glucosidase and protease, while the activities of dehydrogenases, urease and phosphatase did not differ significantly between the treatments.

Based on the analysis of the results, it was shown that metabolic biodiversity indicators differed significantly between the treatments, which indicates various activity within the soil microbiota in individual fertilization systems. The highest substrate richness and Shannon indices were found in both treatments with manure, and the highest overall activity, measured by the AWCD and the ENS indices were determined for treatment with manure and legumes.

In the treatment with mineral fertilization, N-Acetyl-D-Glucosamine, Tween80, D-Xylose and L-Phenylalanine stimulated the growth of microorganisms at the highest level, while in the treatment with legumes, this effect was visible for Phenylethylamine. In the treatment with manure and legumes, the highest values were observed for L-Alanine and Tween 40. However, D-Mannitol was one of the compounds that were used by microbial communities to the greatest extent in all fertilization systems, and the lowest soil microbial growth was observed on 2-Hydroxy Benzoic Acid.

This work was supported by The National Centre for Research and Development in Poland in frame of the project EJP SOIL, Project SOMPACS, contract number EJPSOIL/I/78/SOMPACS/2022.

### THE USE OF MICROBES TO ENHANCE THE GROWTH, PATHOGEN RESISTANCE, AND STORAGE CONDITIONS OF MICROGREENS

G. PERTILE<sup>1</sup>, D. BARANSKA<sup>1</sup>, J. PANEK<sup>1</sup>, K. TURNAU<sup>2</sup>, S. ROZALSKA<sup>3</sup>, M. FRAC<sup>1</sup>

<sup>1</sup> Institute of Agrophysics, Polish Academy of Sciences, Lublin, POLAND

<sup>2</sup> Institute of Environmental Sciences, Jagiellonian University in Kraków, Krakow, POLAND

<sup>3</sup> University of Lodz, Faculty of Biology and Environmental Protection, Department of Industrial Microbiology and Biotechn, Lodz, POLAND

The cultivation of microgreens began in the mid-90s in the USA, and the term “microgreens” has been used since 1998. However, in recent year vertical and urban farming of such plants is increasing. Cultivation of microgreens has started to become important due to their enriched nutritional composition beneficial to humans (vitamins, minerals, fibres, antioxidants, macro-, micro-elements, carotenoids, ascorbic acid, phyloquinone, and phenolic compounds).

The constant market demand for this product has highlighted problems: the yield, storage conditions, quality, safety, resistance, and shelf-life of microgreens. The choice of growth substrate can significantly influence nutritional quality, yield, and dry matter.

The aims of our research will be to improve and optimise the cultivation and storage conditions, yield, quality, safety, and resistance and try to increase the self-shelf period through the application of an adequate bio-stimulated microbes. In fact, by improving the soil microbiome we can suppress disease, improve abiotic resistance, make microgreens resistant. In our study we would like to be able to study the application of beneficial microbes, such as *Bacillus subtilis*, AMF or endophytic fungi on four different microgreens such as coriander (*Coriandrum sativum* L.), basil (*O. basilicum*), radish (*Raphanus sativus* L.), and beetroot (*Beta vulgaris*). The study will include of different fields of research with studying and understanding the microgreens-microbiome interaction to improve production in different cultivation media and understanding the microgreens-microbiome interaction and how it can interact and improve the safety, quality and shelf-life of microgreens.

The results we would obtain from all these different sectors will allow us to understand and explore how the colonization of microgreen plants by the microbial community occurs and how beneficial microbes can improve the organoleptic characteristics of the plants. Knowing these characteristics in depth will allow us to improve the yield, quality, resistance to pathogens, and shelf-life of microgreens.

This work was supported by The National Centre for Research and Development within the framework of the program OPUS-23, contract number 2022/45/B/NZ9/04254.

### EFFECTS OF LOWER ATMOSPHERIC PRESSURE ON ACTIVITY AND DIVERSITY OF SOIL MICROORGANISMS

P. ILLMER<sup>1</sup>, A. MEUL<sup>1</sup>, S. LEMBO<sup>1,2</sup>, B. EL OMARI<sup>2</sup>, G. NIEDRIST<sup>2</sup>, N. PRAEG<sup>1</sup>, M. DAINESE<sup>3</sup>

<sup>1</sup> Department of Microbiology, Universität Innsbruck, INNSBRUCK, AUSTRIA

<sup>2</sup> Institute for Alpine Environment, EURAC Research, Bolzano, ITALY

<sup>3</sup> Department of Biotechnology, University of Verona, Verona, ITALY

Climate change is affecting the composition and functioning of ecosystems across the globe. In alpine ecosystems, species are confronted with new conditions, requiring them to either adjust their life strategies to higher temperatures or migrate to higher elevations to match their thermal preferences. Species moving to higher elevations encounter lower atmospheric pressure alongside unaltered temperatures. The reduced air pressure influences crucial physical parameters such as vapor pressure deficit, gas diffusivity, and CO<sub>2</sub> partial pressure. While the effects of these parameters on plants are well established, little is known about the consequences of moderate atmospheric pressure reduction on free living and plant associated soil microorganisms.

Thus, one of the main goals of the international UPSHIFT project is to assess how soil microorganisms react to lower air pressure in terms of diversity, functional traits, and biomass production. For that purpose, we set up a gradient design by incubating soil-plant mesocosms under lowered air pressures that simulate four elevational levels (260, 1500, 2500, and 4000 m a.s.l.) in hypobaric chambers (terraXcube) while temperature, humidity, gas composition and solar radiation are kept constant at conditions of 1500 m. For each simulated scenario, the reaction of common microbial test strains as well as the effect on soil microbial diversity from both the bulk and rhizosphere soil of three test plants were investigated.

Our results indicate significant effects of pressure reduction on soil microorganisms. We observed a plant-specific alteration of microbial biomass and activity within the rhizosphere fraction. A significant decrease in microbial diversity and richness occurred at lower pressures, corresponding to higher elevations. Importantly, we could confirm that the effects observed in the rhizobiomes were not a consequence of altered plant growth. Our results clearly point out that air pressure reduction, as a facet of climate change, affects soil microorganisms, thus contradicts conventional knowledge and so needs significantly more attention and additional research.

**NOT ONLY THE AMPLITUDE BUT ALSO THE FREQUENCY OF ABIOTIC STRESSORS AFFECTS SOIL MICROBIAL ACTIVITY AND DIVERSITY**

P. ILLMER, T. ALTENBURGER, N. PRAEG

Department of Microbiology, Universität Innsbruck, INNSBRUCK, AUSTRIA

It is well established that climate change is leading to an increased occurrence of extreme weather events such as droughts, floods and temperature extremes. It is also acknowledged that (soil) microorganisms are impacted in activity and diversity by these extreme occurrences. Typically, a clear correlation exists between the intensity of stress and the biological response, whether linear or non-linear. However, since not only the amplitude but also the frequency of disturbances undergoes changes, our objective was to investigate whether and to what extent the frequency of a disturbance, indicating the occurrence rate of an abiotic stress factor, influences the activity and diversity of soil microorganisms.

We conducted experiments with incubated soil to observe the response of soil microorganisms to alterations in two stress factors: temperature and pH. We manipulated the intensity of the disruptive factors, represented by the stress temperature and pH magnitude and also the frequency of disturbances, described by the rate of changes over time. Subsequently, we analyzed the impacts on microbial abundance, activity and diversity by counting colony forming units, measuring enzyme activities and amplicon-sequencing the V3-V4 region of the 16S rRNA gene, respectively.

Both stressors led to significant changes in microbial abundances and activities as well as prokaryotic community compositions. The rise in temperatures led to a shift in the predominant phyla in the soil, shifting from Proteobacteria to Bacillota (formerly Firmicutes). Moderate temperature stress first caused an increase in microbial diversity before a significant reduction was observed at higher temperatures. The varying frequency of a stressor resulted in significant changes, except when the amplitude was too high. This observed pattern was true for both, temperature and pH variations. Overall, we could prove that microbial diversity was significantly affected by both the amplitude and the frequency of a stress factor. Obviously microbial diversity is a complex regulated variable with reactions that are not yet understood, emphasizing the need for further research.

<sup>4</sup> Universität Innsbruck, Department of Ecology, Innsbruck, AUSTRIA

DNA metabarcoding has become standard for characterizing soil microbial diversity. However, to emphasize the interconnectedness of soil, animals, and plants microbiota within the soil ecosystem, suggesting a “OneSoilMicrobiota” concept, methodological advances are needed to efficiently compare microbial communities from matrices typified by contrasting physical and biochemical properties.

Here, we quantified differences in soil ecosystem microbiota between a selection of terrestrial organisms, including above-ground vertebrates, soil invertebrates as well as bulk and rhizosphere soil. Five DNA extraction kits were used to identify a single protocol for processing all samples from the soil ecosystem. As existing pipelines and protocols lack controls for bias in DNA extraction, amplification, and sequencing, we tested the usefulness of a mock community added to a sub-set of these samples before DNA extraction to act as such a control.

From the comparison of five DNA extraction kits commonly used to study soil, feces and invertebrates, we showed that NucleoSpin Soil (Macherey-Nagel; MNS) and QIAamp Fast DNA Stool Mini (Qiagen) extraction kits were associated with the highest and lowest alpha and beta diversity estimates across the different sample types, respectively. The stable performance across sample types indicates that MNS efficiently captures both the composition and diversity of microbial communities found in the terrestrial samples considered in this study, and is in our view recommended for any large-scale ecological study on microbial communities. Our results demonstrate further that an appropriate mock community added directly to a sample before extraction can function as an effective positive control with negligible effect on alpha and beta diversity estimates. The experimental procedures presented here lower methodological variability essential for ecosystem-level microbial diversity studies.

<sup>1</sup> Institute of Biological Research - Department of Experimental and Applied Biology, Iasi, ROMANIA

<sup>2</sup> University of Palermo - Dipartimento Scienze Agrarie, Alimentari e Forestali, Palermo, ITALY

<sup>3</sup> University of Palermo - Dipartimento Scienze Agrarie, Alimentari e Forestali, Palermo, ITALY

The research on soil health is considered of crucial importance as a target objective of the Horizon Europe Program on the EU agenda for the period 2021-2027. To have a comprehensive biochemical characterization of the soil, a soil enzymatic profile is needed, according to the activities of enzymes involved in the bio-geo-chemical cycles of the main elements (C, N, P).

A soil enzymatic assay was conducted in eight benchmark soils (Chernozem, Gleysol, Luvisol and Lithosol) belonging to eight forestry ecosystems from Eastern and Northern Romania, along an elevational transect that encompasses Vaslui county (Lunca Veche; Badeana), Iasi county (Probotă, Ezăreni and Barnova), Neamț county (Vanatori and Manastirea Neamț) and Suceava county (Voronet).

Catalase, dehydrogenase, invertase, urease, acid and alkaline phosphatases were investigated in soil samples related to the abundance and metabolic activity of soil microbes, the biological oxidation of SOM, soil fertility and the soil health. These enzymes were assayed using titrimetric and spectrophotometric methods. The soil enzymatic activities correlated with the morpho-descriptive, physical and chemical soil properties respond to different soils during seasonal dynamic. The redoximorphic processes in the whole soil profile, the climate and the altitude, as restrictive ecological indicators highlighted the lowest dehydrogenase and urease activities in Lithosol of spruce forest Voronet, Luvisol of mixed forest Vanatori and Luvisol of fir forest Manastirea Neamț in seasonal dynamics. The lowest acid phosphatase activity was found in Gleysol of ash forest Probotă and Chernozem of acacia forest Lunca Veche. Opposite to acid phosphatase and mainly produced by soil microbes, the highest alkaline phosphatase activity was found in Gleysol of ash forest Probotă and Chernozem of acacia forest Lunca Veche, correlated with less humified organic matter.

These data highlight the conservative and equilibrium role of the forests on soil microbiome in terms of influence of climatic factors compared to other ecosystems, the enzymatic profile of forestry soils providing the functional indicators with an essential role for the sustainable forest management.

### BIOCRUSTS FAVOR SOIL AGGREGATE STABILITY IN SITES WITH IMPACT OF SUBSISTENCE HUMAN ACTIVITIES IN A TROPICAL MEXICAN DRYLAND

J. SOSA-QUINTERO, A. TORRES GUTIÉRREZ, H. GODINEZ-ÁLVAREZ

Universidad Nacional Autónoma de México, FES Iztacala, Unidad de Biotecnología y Prototipos, Laboratorio de Ecología, Estado de México, MEXICO

Biological soil crusts or biocrusts are edaphic communities composed of cyanobacteria, lichens, and bryophytes in the uppermost few centimeters of surface soil in drylands. Biocrusts act as ecological indicators in erosive processes because they can promote the soil aggregate stability and retain soil. In Mexico, biocrusts are an important component of the temperate and tropical drylands. The study of these communities is recent and their role in preventing soil erosion has not been evaluated. Within the Tehuacán-Cuicatlán Biosphere Reserve, Puebla, in tropical dryland, the subsistence activities have modified the original vegetation. We described the type of human activities at the sites, soil characteristics, taxonomic composition, and cover of biocrusts, as well as the participation of biocrusts in the stability of aggregates. In the study area, there are four sites with different types of management: a site with an irrigation canal for agriculture, a site with trampling by livestock, a ravine with a garbage dump, and a conserved site (without evidence of management). The soils in the four sites are similar: sandy soils, with a pH of 7 to 7.8 and, apparent density between 1.4 and 1.7 g/cm<sup>3</sup>. The percent of soil aggregates was similar between sites; trampling site 38%, ravine site 30%, conserved site 29%, and irrigation site 27%. Biocrusts are composed of 32 species including cyanobacteria, lichens, and bryophytes. The biocrust cover was similar between the four conditions. However, cover in taxonomic groups differed between sites. Therefore, the impact of the activities is modifying the specific cover of the taxonomic groups. In each site, the biocrusts had a specific composition and cover of taxonomic groups. The impact is favoring a greater cover of lichens in sites with livestock, cyanobacteria in ravines, and bryophytes in irrigation and trampling sites. Thus, the impact of subsistence human activities may be modifying the biocrusts cover, and the functional role of each taxonomic group is favoring the aggregate stability.

<sup>2</sup> Institute of Biology Leiden, Leiden University, Leiden, THE NETHERLANDS

<sup>3</sup> Mycology and Microbiology Center, University of Tartu, Tartu, ESTONIA

Afforestation and forest restoration are seen as key factors to mitigate climate change and biodiversity loss given that forests host a major part of the species pool. In Denmark, most of the areas intended for afforestation are former cropland, and their agricultural legacies (high nutrient availability, altered soil biota structure, and function) constrain the development of forest-adapted species, tree growth and stability, ecosystem functions, and biodiversity.

The central hypothesis of Silva Nova is that inoculation of former arable land with soil (including microbiome, fauna, and seeds/rhizomes of understory vegetation) from old forests will improve productivity and more rapidly restore forest-adapted communities. The project will test this hypothesis by 1) evaluating temporal and spatial responses in biomass production, soil biota and soil functions to afforestation in existing chronosequences and sites with increasing distance to other forests; 2) quantifying the effects of inoculation methods regarding donor, amount and application mode to different soil types and tree species through mesocosm experiments; 3) expanding knowledge of inoculation methods from mesocosm to new and existing field-scale experiments; 4) incorporating the landscape context into guidelines and tools for spatially explicit prioritization of areas for promoting dispersal.

Our methodologies link results from state-of-the-art eDNA analyses for above and below-ground microbiome characterization (bacteria, fungi and insects) to vegetation analyses, forest structure (LiDAR), in-situ and laboratory measurements of soil functions (e.g. greenhouse gasses and soil metabolic activity) and soil and plant chemical properties. Silva Nova aims to resolve barriers to successful restoration and develop landscape-scale afforestation strategies that optimize productivity and biodiversity while generating knowledge on the trees, ground vegetation, soil fauna, and microbiome nexus and its effects. Silva Nova is a collaborative effort between the universities of Copenhagen (DK), Leiden (NL) and Tartu (EE), that received a six-year grant from the Novo Nordisk Foundation.

### LAND USE AND BACTERIAL COMMUNITY: AN OVERVIEW ANALYSIS OF BACTERIAL DIVERSITY IN ANDISOLS OF SOUTHERN CHILE

L. LAGOS-PAILLA, B. HENRIQUEZ-CAURAPAN, S. VALLE

Universidad Austral de Chile, Instituto de Ingeniería Agrarias y Suelos. Centro de Investigación en Suelos Volcánicos, Valdivia, CHILE

Chilean volcanic ash soils (Andisols) can be found between Linares (35 51 S-71 36 W) and Puerto Montt (41 28 S -72 56 W). These soils, which are important for the economy of southern Chile, and support the bulk of agricultural and forestry production, can be found as young Andisols (e.g. Acrudoxic Hapludand), well developed Andisols (e.g. Typic or Duric Hapludand), Nadi Soils (e.g. Duric Histic Placaquands) and soils developed from old volcanic ashes such as Ultisols. Andisols exhibit very specific particle properties like variable charge, high phosphate retention and consequently low P availability for plants, low bulk density, large air and water holding capacity. These soil attributes, which are unique and differentiate Andisols from other soil types, are related to the high amount of organic matter and the presence of allophane in these soils. Despite their importance, the interplay between soil factors, bacteria, and land use change (forest, grassland, wetland) in Andisols remains poorly understood. Our analysis of physical, chemical, and bacterial community data across these land uses revealed the complex interactions that shape microbial populations in Andisols. Genomic DNA extracted from soil samples were analyzed by PCR-DGGE and quantitative PCR and metabarcoding of the 16S rRNA gene using the Illumina MiSeq platform. Preliminary, our results have shown that pH, organic matter, bulk density and gravimetric water content have a significant influence on bacterial communities. Moreover, Proteobacteria phyla was the most abundant taxa in the selected soils followed by the phyla Firmicutes, Acidobacteria, Actinobacteria, Verrucomicrobia and Chloroflexi. Our data contributes to understanding the bacterial communities, which are also relevant considering the change in land use and the potential consequences of climate change in southern Chile, including an increase in soil temperature and reduction in rainfall, on water and temperature dynamics as well as bacterial activity in these soils.

**Keywords:** Bacterial community, Land use change, Andisol

<sup>4</sup> Caravella, s.r.o., Tupolevova, Bratislava, SLOVAK REPUBLIC

Paddy soils are highly managed agricultural soils showing unique ecological features. Alternating dry and wet conditions during the growing cycle can promote changes in prokaryotic diversity, soil functioning and nutrient dynamics; particularly carbon and nitrogen cycling, which is intimately related to the soil fertility status and environmental issues. Given the importance of rice cultivation for food provision worldwide, assessing the taxonomic diversity responses to soil management practice becomes decisive for adopting proper sustainable measures. Aim of the present research was to investigate compositional shifts in soil bacterial diversity in a rice-cultivated silty clay loam slightly alkaline Mediterranean soil managed with compost amendment. The experimental design was set-up in a paddy field located in Southern Italy, where rice crop (*Oryza sativa* L. var Karnak) was cultivated over an area covering 250 ha. Experimental plots (~1 ha each, 3-time replicated) were randomly arranged to compare a conventionally managed soil and a soil amended (8 t/ha) with composted municipal solid waste. Surface (10-20 cm) soil samples were taken at five sampling times to investigate immediate vs short- and long-term responses: before the start of the trial (bare and wet soil), 2 days after the compost amendment (bare and dry soil), and then 6 (rice crop and flooding), 17 (rice crop and flooding) and 62 (wet soil) weeks after compost addition. Soil-extracted DNA was amplified with tagged primers targeting the V1-V4 hyper-variable region of 16S rDNA and sequenced by MinION platform (Oxford Nanopore Technologies). Prokaryotic soil communities were largely (> 50%) dominated by oligotrophic Chloroflexi and then Firmicutes and Actinobacteria. The taxonomic assignment evidenced that the compost addition brought about a marked albeit not-persistent increase in copiotrophic Firmicutes (class Bacilli) (2 days after the treatment). Whereas no differences between treatments in major phyla were noticed at following times; thus suggesting that, besides ephemeral compositional changes due to compost-derived substrates and nutrients, soil type and properties created ecological conditions conducive to a resilient bacterial community.

<sup>7</sup> Crop Research Institute, CZECH REPUBLIC

<sup>8</sup> Czech University of Life Sciences, CZECH REPUBLIC

<sup>9</sup> Crop Research Institute, CZECH REPUBLIC

Relict charcoal hearths were studied to assess their impact on biodiversity and soil properties. Their old age reaching several hundred years represents unusual experimental conditions for prediction of charcoal-biochar influence not only on local environmental conditions but also on the stability and recycling of carbon, which has consequences for agriculture and climate change. Ten sites differing in forest type, soil conditions and estimated age of charcoal hearths were selected.

At each site, a phytocoenological relevé was performed and a soil probe was dug at both the hearth and control plot about 25-50 m away. A total of 10 pairs were sampled per site. Soil samples were dried and sieved to measure pH(H<sub>2</sub>O), Al<sup>3+</sup>, Mn<sup>2+</sup>, Fe<sup>3+</sup>, Ca<sup>2+</sup>, Mg<sup>2+</sup>, K<sup>+</sup>, Na<sup>+</sup>, Cox, total N, C, and S contents. Infrared spectroscopy was used to assess organic matter quality and thin sections were used to analyze soil mineralogical composition. Total soil DNA was extracted and amplified with primers for 16S rRNA gene (prokaryotes) and 18S rRNA gene (micro-eukaryotes). Amplicon sequencing was done using Illumina platform and analyzed by Usearch v11.0.667.

PCA revealed large differences between hearths and respective controls in vegetation cover. Soil analyses revealed an increase in pH, CEC and BS mainly in FH horizons, a greater effect was manifested in acidic habitats. Hearths were also enriched in Cox and organic matter had a different composition. Taxonomic composition of prokaryotic (Bacteria and Archaea) communities differed significantly in charcoal hearths compared to controls in all soil horizons. Diversity of prokaryotic communities was significantly increased by charcoal residues at hearths. In the NMDS plots prokaryotic communities at FH horizons appeared the least separated from the other communities of either hearths or controls but the difference was still significant at the  $p < 0.001$ .

In conclusion, biodiversity of soil was significantly higher in charcoal hearths possibly reflecting changed soil conditions particularly increased soil pH and basic cations.

### SOIL MICROBIOME INFLUENCE ON WHEAT AND MAIZE BIOMASS RESPONSES TO DROUGHT STRESS

C. GARZON LADINO, M. DELGADO BAQUERIZO, S. CASTEJON

Instituto de Recursos Naturales y Agrobiología de Sevilla (IRNAS), Seville, SPAIN

Drought stress is challenging food security and agriculture sustainability under climate change scenario. Soil microbiomes are critical for supporting the future of crop production, yet little is known about how changes in soil microbes can influence the capacity of crops to produce food. In this study, we conducted a greenhouse experiment to investigate the growth responses of two major cereal crops, wheat (*Triticum* sp.) and maize (*Zea* sp.), to different microbial inoculums under contrasting drought conditions. Drought reduced crop biomass in both wheat and maize. Moreover, we found that soil microbiomes can regulate the responses of crop growth to drought events.

This study contributes insights into the adaptive strategies of wheat and maize under drought stress and this knowledge is essential for sustainable agriculture, ensuring global food security in the face of climate change.

Dune ecosystems are among the most vulnerable regions to climate change worldwide. However, studies on how crossing critical aridity thresholds influences the microbiome of these ecosystems remain scarce. These microbes play a pivotal role in shaping terrestrial ecosystem traits and functions.

In this study, we collected 1.4-meter sediment cores at 5-cm intervals from deserts in Xinjiang, China, in two study sites before and after crossing a previously described aridity threshold. We conducted a comprehensive analysis of community diversity and spatial structure, in light of the changes in environmental heterogeneity and autocorrelation, further exploring the community's differential sensitivity to fluctuations and evidence of state transitions under various states.

The results demonstrate that microbial communities in sand dunes before and after crossing aridity thresholds exhibit distinct vertical ecological niche differentiation patterns under spatial effects. This includes variations in their beta diversity, rarity mode, assembly process, topological properties, and the stability of their networks. This offers new insights into the possible evidence of microbial community state transitions and potential mechanisms in deserts crossing aridity thresholds.

<sup>4</sup> CREA - Research Center for Agriculture and Environment, FLORENCE, ITALY

Soil biodiversity plays a crucial role in sustaining the ecosystem services and agricultural practices influence the biomass, activity, and diversity of soil microbes, as well as microbial-mediated functions. Here, we aim to assess how the biomass of soil microbial communities, encompassing total, bacterial and fungal components, is affected across a gradient of long-term intensity-gradient of agricultural practices under contrasting climatic conditions at a continental scale. We conducted this experiment using plots with different agricultural practices in eight diverse locations across Europe.

Our findings underscore a pronounced influence of agricultural practices on soil microbial biomass, as estimated by fatty acids. We found notable reductions in bacterial and fungal biomasses as agricultural practices intensified. Besides, bacterial biomass was more susceptible to these perturbations compared to fungal biomass. In response to varying degrees of agricultural practices intensity, soil nitrogen content and pH levels emerge as the main drivers shaping microbial biomass. Furthermore, we observed a significant correlation between soil microbial biomass and nitrogen content, which outweighed the influence of carbon content in all examined soils. This underscores the pivotal role of nitrogen availability in modulating soil microbial biomass and highlights its significance in shaping soil health and fertility.

To conclude, this study advances our understanding of the nuanced impacts of diverse agricultural practices on soil physicochemical properties and their effects on microbial biomass. In this respect, promoting sustainable agriculture practices could foster soil health and resilience to better sustain ecosystem services under a climate change scenario.

### SOIL MICROBIAL DIVERSITY IN MEDITERRANEAN OAK FOREST ECOSYSTEMS SUBJECTED TO UNGULATE GRAZING

S. ZAMBON, A. FIRRINCIELI, A. GALLO, R. MARABOTTINI, S. MARINARI, M. PETRUCCIOLI

Department for Innovation in Biological, Agro-food and Forest systems (DIBAF) - University of Tuscia, Via S. Camillo de, Viterbo, ITALY

This study is part of the PNRR Biodiversity research project, developed within the national network established in order to study how climate change and anthropogenic activities impact the biodiversity in the different ecosystem compartments (soil and vegetation).

The specific research aims of this research are i) understanding the ecological responses of soil microbial community (SMC) to forest environmental change due to ungulate grazing; ii) evaluating the effect of forest grazing on SMC functional and genetic diversity; iii) assessing the impact of forest fenced on C storage and N recycling.

The study was conducted at the natural reserve of Castelporziano (Rome). The experimental area named Campo di Rota is an oak forest grown in soil developed in ancient dune and consists of 12 ha fenced forest and 12 ha unfenced. For statistical relevance, both areas were divided into 9 plots using QGIS. The core sampling was conducted taking the soil in the centre of each plot, under a bushy area, and in a clearing. Then the soil was sieved (2mm) and split in 3 parts to store in different conditions: dry at room temperature for physical-chemical-biochemical analysis, 4°C for the microbiological analysis, and -20°C to preserve the DNA for the metagenomic analysis.

The preliminary analysis of soil (core sampling at 0-10 cm, 10-30 cm, and 30-50 cm) at the qualitative level -chemical-physical analysis, and qPCR assay targeting 16S/18S rRNA genes- show no substantial differences between the two areas under study i.e. fenced vs unfenced. For such reasons, the qualitative analysis - biochemicals and metagenomics analysis- can be used to evaluate how different strategies of forest management have an impact on the soil microbial community and soil biogeochemical cycles in a territory highly sensitive to the effects of forest grazing.

As the global population surges towards 9.8 billion by 2050, the strain on Earth's finite resources intensifies, demanding nearly three times the planet's available natural resources to sustain our current lifestyles. The alarming population growth and environmental degradation have led to a global crisis, threatening our future development and survival. By 2030, one of the primary aims of the United Nations Sustainable Development Goals is to significantly reduce waste generation by prioritizing prevention strategies, implementing reduction techniques, and actively promoting recycling and reuse practices. Management of degradable biowaste and food waste becomes paramount, signalling excessive consumption and necessitating immediate attention through dedicated policies, alongside investments in technology and infrastructure. The thermochemical processing technology for rapid conversion of degradable solid waste into an organic fertilizer is an innovative degradable solid waste management strategy pioneered and patented (No 321857) by the Kerala Agricultural University, harnessing principles of green chemistry. This technology utilizes renewable feedstock and employs thermochemical degradation with specific reagents to rapidly transform waste into thermochemical digestate fertilizer (TDF). TDF, rich in labile carbon, serves as an efficient carbon and energy source for beneficial soil microbes, enhancing their population in soil and facilitating efficient nutrient acquisition by plant roots. Inclusion of the highly beneficial root endophyte, *Piriformospora indica*, with TDF enhanced its proliferation. In a tomato field experiment employing soil test-based fertilizer application, along with *P. indica*-inoculated TDF, results demonstrated a 19.09% increase in the number of fruits per plant and a 24.34% higher fruit yield per plant as compared to conventional fertilizer treatment. Application of TDF, along with such beneficial microbes, served to reduce the external input of inorganic fertilizers by enhancement in nutrient uptake and translocation as evidenced by specific nitrate and phosphate transporters in tomato plants. The reliance on the recycling of degradable solid waste and the efficient crop nutrition derived from the endophytic fungi associated soil organic amendment are an impetus to the concept of circular economy.

### MEDIUM-SIZED HERBIVORES' EXCRETA HAS A SIGNIFICANT IMPACT ON SOIL BIOTA IN A MEDITERRANEAN FOREST ECOSYSTEM

S. PEN-MOURATOV, D. PEN

The Steinhardt Museum of Natural History, Israel National Center for Biodiversity Studies, Tel Aviv University, Tel-Aviv, ISRAEL

Herbivores' fecal depositions are an important source of essential chemicals, such as phosphorus and nitrogen, for soil organisms. The impact of nutrient cycling through feces and urine on soil ecosystems has been well-studied for large herbivores; however, reports on the effects of smaller herbivores' excreta on the soil biota are scarce. To fill this gap, we determined the impact of feces deposition of the Indian crested porcupine (*Hystrix indica*) on the abundance, structure and diversity of the colony-forming units of fungi and bacteria and free-living nematode communities in Israel's Mediterranean region during the annual dry and wet seasons. Results confirmed our assumption that medium-sized herbivores can also have a significant impact on soil communities and their habitats. Fecal deposits of the Indian crested porcupine were found to exert various effects on the observed soil properties, and mainly on the abundance of soil biota. In accordance with earlier findings, we showed that soil properties and the observed external environmental factors have a seasonal effect on the abundance of soil microorganisms and free-living nematodes. Environmental indices confirmed that nutrient supply through the porcupine's urine and feces can have different (stimulatory or inhibitory) impacts on the abundance of the soil communities, affecting the abundance and structure of the colony-forming units of fungi and bacteria and free-living nematode communities during the observed months and seasons of the year.

**Keywords:** herbivores,feces,soil biota,soil microorganisms,free-living nematodes

The studies on agriculture's impact on soil have become very important since they can provide new knowledge for better human and environmental health and protection and for improving agriculture quality. Nematofauna and soil structure were chosen to assess the effects of agricultural practices on soil. The research, which had been underway for almost 20 years, at the time of the research, involved 5 single succession cultivation systems: 1) annual rotation of Italian ryegrass and Zea mays; 2) 3-year rotation of Italian ryegrass + corn – (barley + corn) – (grain corn); 3) 3-year rotation of Italian ryegrass + corn and alternate grass (every six years); 4) permanent grass; and 5) grain maize monoculture. All systems were subjected to 2 levels of agronomic intensification, one optimal (input A) and one lower (input B) where the tillage was replaced by harrowing and the manure was reduced by 30%. The effects of the different cropping systems were compared on soil nematode community (trophic structure, biodiversity, maturity Index, ecological Indices) and soil physic parameters (structure or aggregate stability). Differences in nematode genera composition and distribution among the different agricultural systems were recorded. The Structural Stability Index (SSI) values indicate that the cropping systems had negative effects on the aggregate stability. Crop systems were found to be a significant source of variation, while differences between the two inputs of the same crop systems were more evident considering nematodes rather SSI. Chemical attributes did not seem able to show differences in the impact of the cropping systems with quite a high level of stress. Instead, nematode community parameters were able to underline differences even in those environmental soil conditions highly stressed, with similar management so that it is possible to consider it as an integrative bioindicator suitable for evaluating soil health and/or crop management. Data are linked to the potential ecosystem services provided by nematode communities recorded in the different systems.

### EFFECT OF PLANT DIVERSITY ON OCCURRENCE OF EPIGAEIC AND ENDOGAEIC ARTHROPOD MACRO AND MESOFAUNA IN OILSEED RAPE CROP

I. SMÝKALOVÁ<sup>1</sup>, M. SEIDENGLANZ<sup>1</sup>, L. BLAZEK<sup>1,2</sup>, P. HANAKOVA<sup>1</sup>, R. KUMAR<sup>1</sup>

<sup>1</sup> Agritec Plant Research s.r.o., Zemedelska 2520/16, 787 01 Sumperk, Czech Republic, Sumperk, CZECH REPUBLIC

<sup>2</sup> Palacky University Olomouc, Krizkovskeho 511/8, CZ-779 00 Olomouc, Czech Republic, Olomouc, CZECH REPUBLIC

During three seasons (2020/21, 2021/22, 2022/23) abundance, species richness and spatio-temporal distributions of epigaeic and endogaeic arthropod macro and mesofauna were assessed in winter oilseed rape (WOSR) crops that differed in plant diversity (WOSR monocrop vs. WOSR crops enriched with two different frost-susceptible accompanying plant mixtures; each plot with acreage 0.33 ha). WOSR monocrop has been a part of conventional crop rotation and both more diversified WOSR plots a part of more diversified crop rotation (catch crops and intercrops included). Both crop rotations have been managed at the same trial field in locality Rapotín (Czechia). Sampling was carried out with usage of several types of traps (pitfall, endogaeic and emergence traps). Across the monitoring area the traps were distributed in rectangular grid and emptied 1–2 times per week. In each of the seasons the monitoring activities were divided into two periods: 1) from September to November/December and from March/April –to July/August. Special interest was aimed at carabids (Carabidae), staphylinids (Staphylinidae), spiders (Linyphiidae a Lycosidae), Opilionida and Chilopoda as important predators of larval stages of WOSR insect pests and at Diplopoda, Isopoda, Collembola and earthworms (Annelida, Lumbricina) as indicators of good soil quality. In the last season the monitoring was supplemented with soil samples (0–10 and 10–20 cm) analysed with usage of Berlese-Tullgren funnel on occurrence of Enchytraeids and mites from suborders Oribatei, Pterostigmata, Meostigmata and Astigmata. In epigaeic Carabid fauna slightly higher abundance (insignificant) was recorded in WOSR monocrops in all three years, but species richness (42 against 34 species) and diversity were higher in more diversified WOSR. In more diversified WOSR plots epigaeic even endogaeic carabids, staphylinids and Collembola showed significantly lower tendency to aggregation than in monocrop (Spatial Analysis by Distance indices, SADIE). In more diversified WOSR plots epigaeic even endogaeic carabids and staphylinids showed stronger spatio-temporal association with distribution of Collembola, earthworms and diplopods (Quick Association Analysis).

### NEMATODES: THEIR ROLE AS ECOSYSTEM SERVICE PROVIDERS AND SOIL HEALTH BIO-INDICATORS

B. MANACHINI<sup>1</sup>, W. BERT<sup>2</sup>

<sup>1</sup> Department of Agricultural, Food and Forest Sciences (SAAF), University of Palermo, Palermo, ITALY

<sup>2</sup> Nematology Research Unit, Department of Biology, University of Ghent, Ghent, BELGIUM

Nematodes constitute a very abundant and diverse group of microfaunal organisms that provide various ecosystem services. They play an important role in the soil food web, contribute to soil structure and function, are involved in nutrient cycling and decomposition, and act as biological control agents. On the other hand, they are useful in measuring changes in soil function and status because they are globally distributed and occupy a wide range of habitats, and because they are representative of multiple trophic levels in the soil food web. Moreover, their rapid response to both physical and chemical disturbances makes them valuable for reflecting changes in terrestrial ecosystems. Not only the most common biodiversity indices are applied to this taxon, but also other specific indices based on taxonomic and functional diversity of nematodes and their ecological characteristics. An analysis of the nematode community makes it possible to measure dozens of indicators which provide diverse information, including on the soil fertility (nutrient flow-pathway of degradation of organic matter), the level of disturbance and the risk linked to plant-parasitic nematodes specific to crops or plants. Furthermore, a specific framework is available for selecting a targeted subset of nematode-based indices for diagnosing soil functioning in relation to its use. This presentation introduces the ecosystem functions of nematodes and their role as bioindicators. Key examples are highlighted, and the state of the art understanding of the correlation between nematodes and soil health is elucidated through Vos Viewer analysis. We additionally demonstrate the effective utilization of valuable nematodes bio-indicator tools, particularly emphasizing their application on online platforms. Finally, we highlight educational facets within environmental nematology.

**WHEAT-CLOVER INTERCROPPING CAN INDUCE POSITIVE PLANT-SOIL FEEDBACK WITH MINIMAL IMPACT ON SOIL PHYSICAL PROPERTIES.**

R. PICONE, A. ..S. HASSAN, P. ARFAIOLI, G. PIETRAMELLARA, S. ..I. PATHAN

University of Florence - Department of Agriculture, Food, Environment and Forestry, Florence, ITALY

Sustainable intensification of crop production plays a pivotal role in achieving food security while reducing negative environmental impacts. Based on their physiological complementarity, legume-cereal intercropping could be used to achieve this objective. However, its effects on plant performance, soil edaphic factors and microbial communities are still not fully elucidated. In this study, clover-soft wheat intercropping with an additive design under two N fertilization levels (normal vs reduced) was tested for its effect on crop performance and soil fertility in a one-year field trial. Different plant morphological parameters and yields were evaluated at two times to determine interspecies interactions. Physical properties of soil were evaluated along the profiles. Rhizosphere and bulk soil were sampled to determine their chemical and microbiological properties. A qPCR approach, starting from the total soil DNA, was used to quantify the abundance of microbial phylogenetic markers and functional genes (N and P cycling). Intercropping had limited effects on plant morphological parameters, but system performance was strongly increased (Land Equivalent Ratio > 1). A possible suppression of *Cuscuta* sp. infestation by wheat has also been observed. The physical properties of soil were not affected by the tested factors. Similarly, physicochemical properties were not significantly different between the two niches, except for soil humidity in one case. Fungi were the microbial group most affected by the plant species, as clover increased their abundance in the rhizosphere. The tested factors had different impacts on ammonia-oxidizing bacteria and diazotrophic prokaryotes. The limited effects of the tested factors might be due to high soil fertility. Reducing N fertilization by 30% in intercropping did not induce negative effects because of its positive Plant-Soil Feedback. Therefore, soil diazotrophs may regulate N availability for other microbial groups. Overall, the results indicate that wheat-clover intercropping can be a valid tool for the sustainable intensification of crop production in the Mediterranean climate and has great potential for ameliorating the ecological environment of soil microbial communities.

A prerequisite for the successful introduction of technologies involving the use of beneficial soil organisms (biopelletization, foliar application of algae) is knowledge of their effectiveness in agrosystems. Time-space biomonitoring of large groups of soil organisms such as N-fixing bacteria, mycorrhizal fungi and also algae can detect certain indicators of soil microbiome changes in the long term. The current assumption of consistent monitoring of changes in soil characteristics, including the soil microbiome in the rhizosphere, is influenced by several factors 1) soil characteristics; 2) composition of stands and weeding intensity; 3) frequency of use of legumes in crop rotations; 4) used agricultural technologies. The results of long-term monitoring of the surface layers of the soil horizon at several locations in northern Moravia (Šumperk region) in the Czech Republic pointed to two abundant representatives of soil algae, the genera Klebsormidium and Phormidium. Klebsormidium is a filamentous unbranched charophyte alga indicating changes in the soil environment by the occurrence and change of cell morphology. Phormidium is a filamentous unbranched cyanobacterium with the ability to fix atmospheric nitrogen through heterocysts. A diverse representation of algae was demonstrated in relation to different degrees of weeding, e.g. in caraway crops with herbicide applications. Soil cyanobacteria represent a great benefit in terms of soil properties, especially in relation to soil structure, erosion control and atmospheric nitrogen fixation, similar to their bacterial teammates. Cyanobacteria are also the source of several other elements and substances that in a complex support plant growth (e.g. phytohormones). The use of cyanobacteria for application on the leaf (Tolypothrix, Trichormus) supports controlled production and the possibility of regulating the content of some undesirable substances (toxins) that are applied to the ecosystem by cyanobacteria in natural soil conditions.

Agricultural practices are currently more than ever looking for alternative approaches to soil cultivation, diversification of crops, support the soil microbiome and targeted application of beneficial soil organisms. There are approaches for reducing the use of chemical fertilizers and pesticides, strengthening the tolerance of crops against (a)biotic stresses and improving soil conditions. For purposeful diversification in agroecosystems, a new seed encrustation technology is used to apply beneficial soil organisms (biopelletization) to the soil environment. The inclusion of legumes using biopellets as an accompanying component in crop rotation systems enrich the soil environment with atmospheric nitrogen due to symbiosis with rhizobia, but also with available forms of phosphorus due to the action of specific strains of arbuscular mycorrhizal fungi (*Rhizophagus irregularis*) with profit for the current and next crops. To effectively support the activity and encouragement of desired interactions among the applied organisms, it is necessary to know the soil parameters of the location where this new technology is being applied. The precise assessment of several basic and specific soil characteristics (physical soil parameters – retention water capacity, bulk density, humidity; chemical parameters – content of C, N, P, S, Mg, Ca, K, pH; biological parameters – soil organic matter, diversity and composition of soil microbial communities by sequencing and qPCR) enabled from a long-term perspective to specify the conditions for development of soil beneficial organisms. This is reflected in several monitored crop yield characteristics, including their resistance to dynamic climate changes. The multi-component mixture of crops that share the same location at the same time makes it possible to suppress effects such as susceptibility to fluctuations in the availability of water in the soil. Due to representation of peas in mixture, the main crop (cereals) achieves higher performance and better health. These considerations are supported by our results with the application of biopelletized peas with the aim of diversifying agroecosystems at locations within North Moravia (Šumperk region) in Czech Republic.

### CAN INCREASED ROOT DIVERSITY RETAIN MORE SOIL AND REDUCE SEDIMENT LOSS IN COVER CROP SYSTEMS?

C. MCBRIDE-SERRANO<sup>1</sup>, I. .C. DODD<sup>1</sup>, T. .S. GEORGE<sup>2</sup>, A. .J. KARLEY<sup>2</sup>, J. .N. QUINTON<sup>1</sup>

Agricultural systems need to strengthen their resilience to abiotic stress to mitigate climate change effects on agricultural production and environmental degradation. Increasing plant diversity can help build this resilience by improving ecosystem function through the more efficient use of resources in time and space. While much research has focused on the direct benefits of increased plant diversity for crop productivity, there is limited evidence on how diversity and species selection affect soil stabilisation. Knowledge is lacking in cover crop rhizosphere development, the root-soil interface, that can indicate the soil binding capacity of a plant reducing soil erodibility.

A winter field trial investigated the impact of cover crop diversity on rhizosphere development and soil erodibility by conducting overland flow simulations. Species (*Secale cereale*, *Brassica juncea*, *Vicia faba*) were chosen for their suitability to UK environmental conditions and were sown as single species and in all possible combinations. Results established that root biomass increased with cover crop diversity and was determined by the presence of *Vicia faba*. Rhizosphere formation was not affected by crop diversity and was greater in treatments containing *Secale cereale*. Overland flow simulations showed neither rhizosphere mass nor species diversity had an impact on soil erodibility, and the field variability of soil structural and hydraulic properties had a greater influence.

This work highlights the importance of species selection over diversity, and informs land managers about cropping practices to conserve soil function and restore agroecosystems.

### EFFECT OF CLOVER-WHEAT INTERCROPPING ON SOIL ENZYME ACTIVITIES AND ABUNDANCE OF MICROBIAL BETA-GLUCOSIDASE GENES

G. MARCHETTI, R. PICONE, A.S. HASSAN, P. ARFAIOLI, G. PIETRAMELLARA, S.I. PATHAN

University of Florence - Department of Agriculture, Food, Environment and Forestry, Firenze, ITALY

Current modern agriculture practices such as monocropping, high dosage of chemicals have negative impacts on soil health, biodiversity, and vulnerability to disease. These practices should be replaced by sustainable practices such as use of organic fertilizers, crop diversification etc. Intercropping is one of them that offers a promising alternative to conventional agriculture. It is an ancient agricultural technique in which two or more plant species are grown simultaneously in the same field. In a logic of sustainable development, legume-cereal intercropping has the benefit of maximizing the productivity and efficiency of the agroecosystem, improving the use of resources, and reducing external inputs. However, the ecological processes and mechanisms that regulate this cropping system are not yet fully understood.

The present study aims to evaluate the effect of legume-based intercropping on the edaphic factors and microbial biodiversity of rhizosphere and bulk soils. One year field trial was carried out to determine the short-term effect of wheat-clover intercropping under two levels of nitrogen fertilizers (normal vs reduced) on soil physicochemical properties, enzymatic activities and the abundance of functional genes linked to the cellobiose hydrolysis.

Soil physico-chemical properties did not have any significant impact of soil depth, management practices as well as fertilization treatments, except for soil moisture, which increased significantly in the cereal monoculture in response to reduced fertilizer rates.

Soils from monocultures and intercropped plots contained similar potential for microbial activity. Nonetheless, a significant effect of reduced fertilization and intercropping was observed on alkaline phosphatase activity.

The cultivation strategy and N fertilizer dosages had significant effects on the abundance of fungal and bacterial beta-glucosidase genes. Intercropping significantly increased the abundance of bacterial GH1 family genes in bulk soil, especially under reduced N fertilization. Fungal beta-glucosidase genes were more affected by cultivation strategy and N fertilization compared to bacterial genes especially in rhizosphere soil. Intercropping significantly increase the abundance of fungal genes both GH1 and GH3, especially under reduced N fertilization.

### EFFECT OF LIVING WINTER COVER CROPS ON PESTICIDE CONCENTRATIONS IN SOIL AND SOIL SOLUTION IN TEMPERATE AGRO-ECOSYSTEMS

N. VANDEVOORDE<sup>1</sup>, I. TURINE<sup>1</sup>, A. BLONDEL<sup>2</sup>, Y. AGNAN<sup>1</sup>

<sup>1</sup> Université Catholique de Louvain (UCLouvain), Louvain-la-Neuve, BELGIUM

<sup>2</sup> Centre wallon de Recherches agronomiques (CRA-W), Gembloux, BELGIUM

Throughout the growing season, fertiliser and pesticide applications take place mainly in spring and summer. However, the greatest risk of these chemicals leaching into the soil and water occurs in autumn and winter, when increased rainfall and reduced crop growth facilitate aquifer recharge. While avoiding the use of agrochemicals remains the optimal strategy to prevent soil and groundwater pollution, a number of practices can reduce the risks. As part of crop diversification strategies and in addition to their many other ecosystem services, the effectiveness of living winter cover crops (catch crops) in reducing nitrate leaching during this period is well documented in the scientific literature and has been widely advocated over the years. However, their comparable effect on pesticide leaching remains a generally under-explored area of research. This study aims to determine the potential extension of the removal capacity of catch crops to pesticides, by assessing the influence of a living winter cover crop on residual pesticide levels from the previous growing season in agricultural soils. To this end, we quantify the concentrations of 18 pesticides (9 herbicides, 6 fungicides, 1 insecticide, 2 safeners) in both soil and soil solution samples and compare their evolution over time under three conditions: (i) a winter catch crop (a multi-species cover crop); (ii) a winter cash crop (a winter cereal crop); and (iii) bare soil as a control modality. This comparison is carried out in 10-litre pots in a greenhouse. The cover crops are sown in early January 2024. Soil solution samples are collected three times between January and April 2024, using micro-rhizons (Rhizosphere®) and are analysed by LC-MS/MS for the quantification of pesticide and residue concentrations. Soil samples are collected according to the same schedule, extracted using QuEChERS and processed by LC-MS/MS. The experiment will be completed in April and aims to provide critical insights into the potential of living winter cover crops to mitigate pesticide leaching into agroecosystem soils and aquifers.

<sup>2</sup> CIRAD, MONTPELLIER, FRANCE

<sup>3</sup> AGROSAVIA C.I TIBAITATA, MOSQUERA, COLOMBIA

<sup>4</sup> AARHUS UNIVERSITY, AARHUS, DENMARK

The coffee crop is one of the most important farming systems for Colombia, allowing its economic development and recognition, as well as allowing the substitution of illicit crops, as occurred in the south of Meta department. However, due to the armed conflict in this region, research hadn't been carried out focused on estimating the effect of coffee production on soil microbial and enzymatic activity, and likewise, very little research generally considers the effect of the agronomic practices on these variables. Considering the above, 40 semi-structured surveys were conducted with coffee growers to identify their agronomic practices. Additionally, soil sampling was carried out in each of the farms, where the age and type of associated crop in each coffee crop were considered, taking at least three random samples from each of the coffee crops visited, for a total of 150 samples collected. To select the explanatory variables (agronomic practices) of greatest relevance concerning the response variables, a principal components analysis was carried out, which allowed redundant variables to be eliminated, and non-collinearity was also verified. Likewise, the farmer's perception of the identification of dry season, organic carbon, pH, soil particle size distribution, and acidity were selected as covariates. For the response variables, the enzymes related to the C, P, and S nutrient cycling (Beta-glucosidase, acid and alkali phosphatase, and arylsulfatase, respectively) and dehydrogenase were measured. We also recorded the cumulated microbial respiration and the basal respiration rate. To analyze the effect of explanatory variables and covariates, a partial redundancy analysis was used, which allowed us to identify that the covariates represented 23% of the variability in soil microbial and enzymatic activity, while the agronomic practices explained 33%. Finally, a statistically significant model ( $p < 0.001$ ) could be identified that managed to explain 27.2% of the variability between sites. The previous results allow us to infer the need to include the identification of the farmer's agronomic practices when evaluating the microorganisms' activity.

**Keywords:** Soil enzymes,Basal respiration,Explanatory variables,Partial redundancy analysis

### INFLUENCE OF INNOVATIVE AGRICULTURAL PRACTICES ON REDUCING PESTICIDE AND NITRATE TRANSFER IN MAIZE MONOCULTURE

Y. AGNAN <sup>1</sup>, L. ALLETTO <sup>2</sup>, L. BOITHIAS <sup>3</sup>, S. GIULIANO <sup>4</sup>, C. DESWARTE <sup>4</sup>, F. PERDRIEUX <sup>4</sup>, A. PELLETIER <sup>5</sup>

<sup>1</sup> Earth and Life Institute - UCLouvain, Louvain-la-Neuve, BELGIUM

<sup>2</sup> AGIR - Université Fédérale de Toulouse, Castanet-Tolosan, FRANCE

<sup>3</sup> Géosciences Environnement Toulouse, Toulouse, FRANCE

<sup>4</sup> INP-PURPAN, Seysses, FRANCE

<sup>5</sup> Chambre d Agriculture de l Ariège, Villeneuve-du-Paréage, FRANCE

Maize represents a third of the cultivated area in Ariège, southwestern France. Controlling pests requires the use of pesticides that are dispersed in soils and natural waters. However, some agricultural practices may modify their transfer into the environment: reduced tillage, organic amendment, pesticide application management. The objective of this study was to evaluate the influence of these innovative agricultural practices on the pesticide and nitrate transfer in irrigated maize monoculture by studying the soil solution for four consecutive years. On each study site, a reference modality was compared to: (1) a reduced tillage modality; (2) a reduced tillage modality with addition of organic matter; and (3) a localized pesticide application modality (i.e., herbicide application only on the maize rows to reduce the dose applied). In total, nitrates and 32 pesticides (including 16 herbicides, 3 insecticides, and 6 fungicides) were analyzed in soil solutions at 50 cm soil depth collected by suction cups. Pesticide concentrations showed a high variability within each molecule (with an average factor of 4000) and between the molecules measured (with an average factor of 1000). The highest concentrations (median concentration  $>1 \mu\text{g L}^{-1}$  and maximum of  $2331 \mu\text{g L}^{-1}$ ) was observed for S-metolachlor and its metabolites. The results did not show significant differences between the modalities in the experimental conditions tested. Using partial least square regression and decision trees, environmental variables such as organic carbon content, soil pH, and soil water stock, however, were dominant in controlling the transfer of pesticides by limiting or promoting their presence in the soil solution. The temporal factor was also a key factor, favoring the dissipation and/or degradation of molecules (in particular for S-metolachlor, glyphosate, and azoxystrobin), while the concentrations observed during the fallow period were relatively higher than those measured at the end of the previous culture. The trends observed were, however, largely dependent on the physicochemical properties of the molecules studied, controlling their dynamics in the environment.

**Keywords:** pesticides,transfer,soil,solution,practices

### REVEALING THE IMPACT OF COVER CROPS ON SOIL FUNCTIONALITY AND BIODIVERSITY IN APPLE ORCHARDS

R.R.T. NOTO <sup>1</sup>, M. MAVER <sup>2</sup>, R. TIZIANI <sup>1</sup>, E. TASKIN <sup>1</sup>, S. CESCO <sup>1</sup>, L. BORRUSO <sup>1</sup>, T. MIMMO <sup>1,2</sup>

<sup>1</sup> Faculty of Agricultural, Environmental and Food Sciences, Free University of Bolzano, Bolzano, ITALY

<sup>2</sup> Competence Centre for Plant Health, Free University of Bolzano, Bolzano, ITALY

Cover crops are a valuable food source for microorganisms and soil fauna, shaping key biogeochemical cycles in agricultural ecosystems and carbon (C) sequestration. The study aims to evaluate the impact on soil microbial functionality and biodiversity of two distinct cover crop mixtures (Hühnerauslauf, a mixture of low-growing grasses, and Südtirolmischung, which contains predominantly Leguminosae). In close cooperation with regional farmers, the study is carried out in six different apple orchards in South Tyrol, Italy, each characterized by differing agronomic practices. Soil samples are collected at two depths (topsoil: 0-30 cm, subsoil: 30-60 cm) three times a year (spring, summer, and fall). Soil microbial functionality is examined by measuring soil respiration and specific enzyme activity linked to the C cycle. As expected, the topsoil has higher respiration rates than the subsoil. Furthermore, results indicate that the time of sampling significantly affects soil respiration, implying that climatic or meteorological factors play a key role in influencing respiratory dynamics. The selected enzymes are currently being studied. This study can help us understand how cover crops affect soil biological functions and processes, which are essential to laying the foundation of agroecological strategies that promote C sequestration.

<sup>2</sup> Department of Agriculture, Food, Environment and Forestry, University of Florence, Florence, ITALY

Modern agriculture, characterized by its reliance on chemical inputs and non-renewable energy sources for high yields, is facing scrutiny due to its adverse impacts on public health and the environment. Recent revelations underscore the need to shift towards a more sustainable model incorporating ecological principles and ecosystem services, minimizing the use of chemicals and non-renewable energy. This alternative approach, termed agroecology, emphasizes the design of cropping systems to enhance both sustainability and production efficiency.

Adhering to agroecological principles involves adopting various practices with intercropping, crop rotations, cover cropping, green manure, reduced tillage, agroforestry. Among these practices, intercropping, cultivating multiple crops simultaneously on the same land, is particularly promising, as it offers substantial optimization of cropping systems through diversification. In these systems, legumes are a key functional group and highly valued for the agroecological services they provide.

The intercropped legume-cereal systems reduce interspecific competition by enhancing complementarity/facilitation processes thereby improving the exploitation of resources, which is, in turn, reflected in the increase in plant production corresponding to the greater efficiency of the agroecosystem. Plant production, including above- and belowground biomass, is positively correlated with microbial abundance and diversity. This microbial life is assumed to play a significant role in the availability and transfer of soil nutrients to plants as well as in plant health and soil fertility.

Despite the importance of these interactions, limited research has explored the functional and genetic diversity of soil microorganisms in intercropped legume-cereal systems. The intricate nature of both the soil microbiome and plant holobiont has created considerable uncertainty regarding how different crop species influence the shaping of soil microbial communities, particularly the bacterial and fungal microbiomes in legume-cereal intercropping. Therefore, the aim of this ongoing study is to determine the functional and genetic diversity of microbial communities inhabiting the soil, rhizosphere and plant compartments in legume-cereal intercropping.

The introduction of Urochloa grasses in rotation with maize is a viable option in tropical regions to mitigate nitrogen (N) losses from the soil as nitrous oxide (N<sub>2</sub>O). Urochloa grasses are known for their deep rooting ability and the improvement of soil properties as observed in permanent pastures. However, the specific impact of Urochloa grasses on soil health when introduced as a cover crop in rotation with maize is unknown. The main objective of this study was to evaluate the residual effect of Urochloa grasses on soil aggregation and soil macrofauna of the subsequent maize crop. The field trial was established in 2016 with the planting of nine Urochloa grass genotypes in 20 x 20 m plots (n=3), along with three control plots left as bare soil treatments. At the end of 2019, maize was introduced to half of each plot, resulting in a comparative analysis between permanent grasses, maize grown on previous grass plots and those on bare soil, alongside conventional maize treatments. Soil samples collected in 2023 from a 0-20 cm depth across the treatments revealed that permanent grasses significantly promote higher aggregate stability (mean weight diameter, mm), due to a higher proportion of macroaggregates (water-stable aggregates > 2mm). These results can be explained by the origin or formation pathway of soil aggregates, because in the treatments with permanent grasses a higher proportion of aggregates of root origin was obtained (about 15%). We found that soil aggregates in maize grown on previous grass treatments were more stable (42%) than those from conventional maize treatment. A total of 10 groups of soil macrofauna were identified, the most diverse groups were found in maize grown on a previous grass treatment, which were related to groups that live on the soil surface (Diplopoda, Symphyla and Diplura). Results from this study indicate that Urochloa grasses grown as cover crops could provide soil health benefits linked to soil structure and soil organic carbon sequestration.

### EXPLORING THE IMPACT OF REGENERATIVE AGRICULTURAL MANAGEMENT PRACTICES ON SOIL MICROBIOME COMPOSITION AND ACTIVITY

B. DI BIASE <sup>1</sup>, J. ROSE <sup>2</sup>, B. STEINKRAUS <sup>1</sup>, M. SCHAKS <sup>1</sup>, A. SPIESS <sup>1</sup>

<sup>1</sup> Soilytix GmbH, Hamburg, GERMANY

<sup>2</sup> Technische Universität Hamburg - Institut für Abwasserwirtschaft und Gewässerschutz, Hamburg, GERMANY

Increased concern over the rate of soil degradation and biodiversity loss within agroecosystems has prompted a shift from conventional to regenerative management practices. Cover cropping and shallow tilling are two practices widely associated with soil regeneration as opposed to leaving soil bare and conventional tilling. The soil microbiome is central to plant growth, soil fertility and overall agricultural sustainability. Its composition and activity are highly susceptible to shifts in management and serve as early stage indicator of soil health. However, empirical data characterizing soil microbial parameters in response to shifts in agricultural management practices remains scarce and disparate.

We assessed the taxonomic and functional composition of soil fungal and bacterial communities extracted from a sectioned homogenized plot subjected to shallow tilling and cover cropping, shallow tilling without cover cropping, conventional tilling and cover cropping, and conventional tilling without cover cropping. Extracellular enzyme activity was quantified to assess microbial activity. Soil sampling was repeated in June, August and September to assess seasonal variability. Targeted metagenomics sequencing of the V4 region of 16S-rDNA and the ITS1 region of ITS-rDNA was conducted to respectively identify soil bacterial and fungal community composition. Bacterial and fungal functions were assessed using FAPROTAX and FUNGuild respectively. Activity of  $\beta$ -glucosidase (BG), acid phosphatase (AP) and N-acetylglucosaminidase (NAG) was colorimetrically determined.

Thus far, metagenomics analysis of the first time point revealed shifts in microbial community composition and activity. Fungal alpha-diversity significantly increased when shallow tilling was applied rather than conventional tilling. However, fungal alpha-diversity was unchanged with respect to cover cropping, suggesting that tilling regime has a profound impact on fungal communities that cannot be remediated by cover cropping between growing seasons. BG, AP and NAG activity significantly increased when cover cropping was implemented rather than leaving soil bare. BG, AP and NAG activity was unchanged relative to tilling regime. Thus far our soil analysis might indicate that tilling and cover cropping affect soil health via distinct, non-trivial mechanisms.

### ENHANCING SUGARCANE HEALTH: SUSTAINABLE STRATEGIES FOR FUSARIUM CONTROL THROUGH CROP RESIDUE MANAGEMENT

L.C. LOPES FILHO <sup>1</sup>, L. .F. FERREIRA SILVA SANT'ANA <sup>2</sup>, M. HIDEKI ESAKI <sup>2</sup>, A. RUBIO NETO <sup>3</sup>, J. BELEM DE MOURA <sup>1</sup>

<sup>3</sup> Instuto Federal Goiano - Campus Rio Verde, Rio Verde, BRAZIL

The use of crop residue in sugarcane as a measure for controlling fungal diseases has proven to be an efficient and sustainable practice in agriculture. Fusarium wilt, caused by *Fusarium oxysporum*, is of significant importance in various sugarcane-producing regions worldwide and can cause serious damage to plantations. One of the major issues is the persistence of the pathogen in the soil. The fungus penetrates the roots and colonizes the vascular system, disrupting the proper flow of water and nutrients to the upper parts of the plant.

For the genomic DNA extraction process from soil samples, the DNeasy® PowerSoil® Pro Kit (Qiagen) was utilized, following the manufacturer's established protocol. Specific primers for the identification of *Fusarium oxysporum* were used for qPCR analyses. Three cultivation types were evaluated: reel and pivot with their respective irrigations, and non-irrigated cultivation. Regarding crop residue management, collection was assessed after 1 year, 2 years, and with no residue collection.

There were differences in the years evaluated for residue collection. The reel irrigation had the highest pathogen population in the first year, while non-irrigated and pivot had the highest population in the second year of residue collection. For the no-collection treatment, there was no difference in pathogen population. In terms of irrigation, within the first year, the reel had the highest pathogen population again. In the second year, it was precisely the reel that had a lower population, indicating that with 2 years of residue collection, the reel seems to have a greater impact on reducing the population of *Fusarium oxysporum* for sugarcane. For the year with no residue collection, the pivot had a higher pathogen population. In conclusion, this study underscores the nuanced impact of irrigation methods and residue collection timelines on pathogen populations, providing valuable insights for optimizing agricultural practices and promoting the long-term health and productivity of sugarcane plantations worldwide.

<sup>5</sup> Food and Wine Research Institute, Eszterházy Károly Catholic University, Eger, HUNGARY

Terroir, defined as a man-made ecosystem where the vine interacts with soil and climate, emphasizes the importance of understanding the specificities of the production environment for quality wine production. Global and local climatic variations significantly impact vine- growing areas, microclimates, and grape- and wine quality. Implemented in vineyards in Tokaj wine region with varying soil types (loamy, sandy loam, and clayey) and climatic conditions, the underrow cover experiments focus on soil biological effects and grapevine responses. Employing consistent grapevine varieties (*Vitis vinifera* L. convar Furmint) and rootstocks ('Richter 110' *Vitis berlandieri* × *V. rupestris*) ensures comparability for physiological measurements of vines, enabling the detection of terroir differences and effects induced by under-row covers. In our research, we examined the soil components of the wine terroir by physical, chemical, and biological measurements. The treatments used were Lucerne hay and underbelly wool as row cover. As a ground cover, mulch affects water retention, nutrient availability and microbial activity, influencing the expression of terroir. Based on our preliminary results, we determined that the enzyme tests related to the nutrient cycle in the soil (phosphatase, glucosidase) did not show any significant difference after the short time that had passed since the planting in the spring of 2023. In case of the FDA enzyme used as an indicator of biological activity, a higher activity value was observed in wool- covered treatments. In summary, studying the soil component of the wine terroir through research on soil covers like mulching offers insights into various aspects of vineyard management, ranging from water conservation and weed control to soil health and sustainable practices, ultimately influencing grape quality and wine characteristics in the unique terroir of Tokaj. Researching its effects aligns with the global trend toward sustainable agriculture and can provide evidence to support environmentally conscious viticultural practices. This multidisciplinary approach can help to preserve the current terroirs and identify new opportunities.

The rhizosphere is recognized as the environment with the highest biological activity on Earth's surface. This space is where root exudates converge with the rhizosphere microorganisms, taking advantage in the rapidly available source of carbon and energy utilized by millions of bacteria and fungi, many of which promote plant growth or enhance the nutritional characteristics of agrifood products, thereby increasing plant tolerance to various environmental stresses. This is crucial in a scenario dominated by climate change, which is negatively affecting agricultural production needed to sustain the growing global population. However, the coexistence of diverse groups of microorganisms in microbial communities generates a range of ecological relationships that can be synergistic, neutral, or even detrimental. Therefore, it is necessary to understand the compatibility between different microorganisms intended for use and their impact on native soil communities where they will be inoculated. This adds a higher degree of complexity, which must include a deep understanding about how other agricultural or environmental management alternatives can 'condition' the rhizosphere to favor plant establishment and growth, referred to as rhizosphere management or rhizosphere engineering. Here, we present the most relevant experiences and results obtained by our research group regarding the use of Plant Growth-Promoting (PGP) microorganisms, with a special focus on arbuscular mycorrhizal fungi (AMF), free-living yeasts, and bacteria, which have been isolated from a wide range of extreme environments in Chile (Atacama Desert, high mountains, contaminated soils, and Antarctica, among others). Emphasis will be placed on results demonstrating their benefits in environments dominated by toxic elements, drought, and salinity. Finally, we will discuss their projections in the current scenario of global climate crisis, including a comprehensive overview from their isolation in extreme environments, their characterization in plant growth promotion, and the feasibility of their use in consortia designed à la carte to be used as inoculants for different agricultural species.

### OVERCOMING BARRIERS TO THE ADOPTION OF INTERCROPPING IN THE UK

I. UWASE<sup>1</sup>, J. ALFORD<sup>2</sup>, J. HAMMOND<sup>1</sup>, M. THORSOE<sup>3</sup>, S. PATHAN<sup>4</sup>, T. SIZMUR<sup>1</sup>

<sup>1</sup> University of Reading, Reading, UNITED KINGDOM

<sup>2</sup> Soil Association, Bristol, UNITED KINGDOM

<sup>3</sup> Aarhus University, Aarhus, DENMARK

<sup>4</sup> University of Florence, Florence, ITALY

Conventional cropping deteriorates soil quality and reduces biodiversity. There is an urgent need for more sustainable yet productive systems. Intercropping involves growing two crops together, enhancing biodiversity and productivity. However, few UK arable farmers practice intercropping. We held a workshop with farmers and stakeholders to conduct a SWOT analysis of intercropping. The key strength identified was improving biodiversity and resilience. The main weakness was “the need to separate and market the product. The major threat was lack of knowledge. The main opportunity identified was “increasing in grain protein and reducing nitrogen use.

The LEGUMINOSE project aims to reduce the barriers to intercropping by conducting applied scientific research. 20 on farm trials are being established across the UK to compare legume/cereal intercropping with their respective monocultures. The overarching objectives of the trials are to determine whether intercropping could (i) reduce the use of pesticides by suppressing weeds, pests and pathogens and improving beneficial species; (ii) improve soil fertility by increasing belowground biomass and thus C sequestration and reduce GHG emissions and (iii) increase the yield of the main crop. Field trials have been established on the University of Reading research farm. Our preliminary data indicates that the land equivalent ratio generally decreases when applying nitrogen fertiliser to cereal/legume intercrops. However, applying a higher rate of nitrogen results in a greater land equivalent ratio than applying a low amount.

Our future trials will attribute intercropping yield benefit (land equivalent ratio) to nitrogen supply or other factors by combining wheat with legumes (faba beans, lupin and soybean). These trials will provide data for farmers to decide how much less nitrogen to apply to wheat intercropped with legumes while retaining premiums for grain protein content and maintaining biological nitrogen fixation. Measurements include crop yield and quality (e.g. N content of grain) and nitrogen losses through emissions and leaching. The poster provides the rationale for our trial designs for the purpose of obtaining peer feedback.

Department of Geography and Environmental Science

## Overcoming barriers to the adoption of intercropping in the UK

Tom Sizmur | Jerry Alford | John Hammond | Martin Thorsoe | Imelda Uwase | Shamina Imran Pathan

### Introduction

Intercropping is when two crops of different species are grown together in the same field at the same time. Intercropping can enhance biodiversity, maximise land productivity, and optimise biogeochemical cycles in agroecosystems. However, intercropping is adopted by very few UK arable farmers.

### Workshop outcomes

We held a workshop with UK conventional and organic farmers and other stakeholders to conduct a SWOT (Strengths, Weaknesses, Opportunities, and Threats) assessment of intercropping in the UK.

<p><b>Strength</b></p> <p><i>the opportunity to improve farm biodiversity and resilience</i></p>	<p><b>Weakness</b></p> <p><i>the need for separation and a market for the product</i></p>
<p><b>Opportunity</b></p> <p><i>an increase in grain protein content and a reduction in nitrogen use</i></p>	<p><b>Threat</b></p> <p><i>the lack of knowledge to get it right</i></p>

### The LEGUMINOSE project

The LEGUMINOSE project aims to reduce the barriers to intercropping by conducting applied scientific research. Twenty on-farm trials will be established across the UK to compare legume and cereal intercrop mixtures with their respective monocultures.

Contact information  
- Email: [tsizmur@reading.ac.uk](mailto:tsizmur@reading.ac.uk) | [www.reading.ac.uk/ges/](http://www.reading.ac.uk/ges/)

### Preliminary research trials

Field trials have been established on the University of Reading research farm. Our focus is on combining wheat crops with legumes. Our preliminary trials used legumes that have previously performed well in prior field experiments (faba beans and lupins) and an emerging UK crop (soybeans). Wheat and faba beans were planted in autumn 2022. Wheat and lupins or soybeans were planted in spring 2023. We observed poor establishment of lupins and soybeans due to cold weather in spring 2023. Our preliminary data indicates that the land equivalent ratio generally decreases when applying nitrogen fertiliser to cereal/legume intercrops. However, applying a higher rate of nitrogen results in a greater land equivalent ratio than applying a low amount.

### Future research trials

Our future research trials specifically aim to attribute the yield benefit that intercropping makes to the supply of nitrogen, or to other factors. We have designed the trials to provide data that will enable farmers to decide how much less nitrogen they need to apply to a wheat crop to achieve milling quality grain when the wheat is intercropped with a legume.

Measurements will comprise crop yield and quality (e.g. N content of grain), nitrogen losses ( $N_2O$  emissions and  $NO_3^-$  leaching) and soil physical, chemical, and biological properties that underpin soil health (e.g. soil structure, nutrient availability, organic matter, and microbial activity).

## 4. Soil health in achieving the Sustainable Development Goals 4.10 133439 - Soil health implications of adapting to the Planetary Health Diet

### IMPLICATIONS OF THE PLANETARY HEALTH DIET TO THE NITROGEN ISSUE: A SOIL HEALTH AND FOOD SECURITY PERSPECTIVE

K. HAYASHI

Research Institute for Humanity and Nature, Kyoto, JAPAN

Nitrogen (N) issue is a trade-off between the benefits of N use as fertilizers and industrial materials and the threats of various N pollution such as climate change, air pollution, and eutrophication due to the human-induced reactive N (N compounds other than inert molecular N) loss to the environment. It has been assessed repeatedly that human-altered N cycling has transgressed the planetary boundaries since its first report in 2009. One of the fundamental reasons of the N pollution is the low N use efficiency in food system, where N use efficiency (NUE) of animal production tends to be lower than that of crop production. The planetary health diet based on plant-based food is effective also to mitigate the N pollution. Even the NUE of crop production is not high, and therefore high N input crop production results in the N loss from cropland to the environment and imbalance of soil health in terms of eutrophication. On the other hand, in countries where fertilizers are difficult to obtain due to economic conditions, there are concerns about soil health degradation and food insecurity due to exploitation and overuse of cropland soil. Planetary health diet can be diverse, and each country and region should have its own model based on its soil, climate, traditions, and food culture. In this regard, consideration should also be given to the international supply chain of food and feed commodities. The presenter is working on inter- and trans-disciplinary research to address the N issue as the leader of Sustai-N-able Project (<https://www.chikyu.ac.jp/Sustai-N-able/en/index.html>) funded by the Research Institute for Humanity and Nature, Japan as well as the director of the East Asia Regional Centre of International Nitrogen Initiative. An important action is to promote awareness of the N issue to various stakeholders and to facilitate their engagement.

### SEEDLING PRODUCTION AND TOP DRESSING FERTILIZATION FOR THE ESTABLISHMENT OF BARUZEIRO (DIPTERYX ALATA VOGEL) IN A RED LATOSOL IN THE CERRADO BIOME

H. MOURA GONCALVES <sup>1</sup>, F. AQUINO <sup>1</sup>, J. MALAQUIAS <sup>1</sup>, N. DURAES <sup>2</sup>

<sup>1</sup> Embrapa, Brasília, BRAZIL

<sup>2</sup> Universidade de Brasília, Brasília, BRAZIL

The baruzeiro (*Dipteryx alata* Vogel) has high potential for food, timber and medicinal use. It is among the species with high demand for domestication, promoting the diversification of species in cultivation, consolidation of its production chain and expanding the sources of obtaining the fruit, which currently come exclusively from extraction in areas with native vegetation. To this end, an experimental plantation was set up at Embrapa Cerrados (Planaltina, DF) with the aim of evaluating the establishment of two baruzeiro progenies subjected to three levels of top dressing under field conditions. The seedlings were produced in nurseries from the seeds of two selected matrices, progenies G1 and G2, from the Embrapa Cerrados germplasm bank. The experimental design was in randomized blocks with three replications and a factorial subdivided plot layout, with two factors being studied (fertilization and progeny) and levels of top dressing fertilization with increasing doses of nitrogen, phosphorus, potassium and boron (T1, T2 and T3) being allocated to the plots (32 plants) and the progenies to the subplots (16 plants). The spacing between plants was 7 m x 7 m, totaling 288 plants in the experiment. The development of the plants was assessed at 3, 6, 9, 12 and 18 months after planting, by verifying neck diameter, plant height and crown volume. The results showed that at 6 months the G2 progeny stood out in terms of height growth. At 9 months, the dry season contributed to a reduction in crown volume. Up to 12 months, there was no significant interaction between the levels of fertilization and the progenies for all the variables evaluated, and with the return of the rainy season, the plants resumed growth. At 18 months after planting, there was a significant interaction between the progenies and the top-dressing treatments. The response to maintenance fertilization was different between the two genotypes studied.

**THE TERM AGRICULTURE NEED TO DIVIDE FOOD PRODUCTION FOR ANIMALS (COWS, PIGS, CHICKENS MAINLY) AND FOOD FOR HUMAN CONSUMPTION**

A. CHACALO<sup>1</sup>, L. ARRIAGA<sup>1</sup>

<sup>1</sup> UAM-AZCAPOTZALCO, CDMX, MEXICO

<sup>2</sup> UAM-AZCAPOTZALCO, CDMX, MEXICO

In the past 4th Global Soil Security Conference (Seoul, 2023) important conceptual concepts were treated equally.

When speaking about soil security, soil depletion, soil erosion, soil risks or environmental pollution (air, soil and water) it will be very helpful to know that it is not the same to produce food to feed the cattle and the farmed animals, than to feed people.

The amount of land (deforestation), water, and pollution generated to produce food for animals is much bigger than what will be needed to feed humans with fruits, flowers, vegetables, seeds, grains, roots, or fungi. Without meat or animal products.

How are we going to secure food production for the next years to come? Depleting the soil, the land and the water, the environment and the biodiversity; or working as scientists, professors and professionals to educate the population in the consumption of much less harmful food?

The change suggested will not only improve the soil and environment. Several studies have shown that the population living in rural areas without consuming meat is in much better health condition compared to urban areas with highest consumption of meat and animal products.

In addition, this will promote a much more respectful relationship with other sentient animals avoiding killing billions each year. Industrial agriculture (the vast majority) has the animals living in deplorable conditions of overcrowding. Even in the best slaughterhouses, animals die horribly. As Paul McCartney said: if slaughterhouses had glass walls...

Cultural changes need to be guided by knowledge, not by the lobby of important companies to save their brands and interests.

More people live on the planet now compared to all other eras and 5 times more meat and animal products are available now due mainly to industrial agriculture.

We do not need anymore animal foods to get proteins. A plant based diet will feed many more people in the future and without harming the environment and the animals and additionally improving our own health.

## 4. Soil health in achieving the Sustainable Development Goals 4.11 133521 - Caring for mountain soils, the hidden key to climate change adaptation and SDGs: challenges, threats, success stories

### SOIL QUALITY CHANGE AND SPATIAL DIFFERENTIATION CHARACTERISTICS OF GREENHOUSES LAND SOIL IN LHASA RIVER VALLEY, QINGHAI-TIBET PLATEAU

Y. ZHANG, D. GONG, Z. WANG, X. HU, C. GU, B. WEI

Institute of Geographic Sciences and Natural Resources Research of CAS - Depart. of Land Change Science  
& Biogeography, Beijing, CHINA

Soil quality problems often arise in the process of greenhouse agriculture pursuing economic benefits. There are also signs of soil quality changes in the Qinghai-Tibet Plateau greenhouse land, and the regional differentiation pattern of soil quality changes in the Lhasa Valley. Taking the arable land soil samples as the references, this study collected 240 soil samples of greenhouse land and 112 soil samples of arable land. The texture, pH value, organic matter, soil heavy metals elements etc. were determined. The comprehensive soil quality index (SQI) and factor detector methods were used to study the soil quality changes and spatial differentiation characteristics, and the main factors of soil quality changes in the greenhouse land soil were identified. The results showed: 1, The comprehensive soil quality indices of the Lhasa valley greenhouse land and the arable land soil were 0.36, and 0.43, respectively. The soil quality of the greenhouse land was relatively high on the sunny slopes within 930 m from the river at an altitude of 3,700~3,750 m. 2, There were spatial differences in the degree of soil quality variation in the study area. The SQI of the greenhouse land decreased by 16.28% on average compared to that of the larger field farmland. 3, There was spatial heterogeneity in soil quality changes in the greenhouse land affected by altitude and slope direction. With the increase of elevation and the change of soil quality from sunny slope to shady slope, the change of soil quality in the agricultural land facilities showed a significant trend of increase. 4, The soil quality change in the whole region was generally affected by changes in salt content, available potassium and cadmium content and the explanatory power of all three could reach 20%. Under the changing influence of salt accumulation, available potassium and cadmium content changes, the overall soil quality of the study area's greenhouse land showing a decreasing trend and varied significantly in different regions.

### ASSESSING AND MAPPING SOIL-BASED ECOSYSTEM SERVICES OF THE EMILIA-ROMAGNA APENNINES

F. UNGARO<sup>1</sup>, P. TAROCCO<sup>2</sup>, A. APREA<sup>2</sup>

<sup>1</sup> Consiglio Nazionale della Ricerche, Istituto per la BioEconomia, Sesto F.no, ITALY

<sup>2</sup> Regione Emilia Romagna, Area Geologia Suoli e Sismica, Bologna, ITALY

This work presents the results of the implementation of a methodological framework to assess and map the multiplicity of soil-based ecosystem services, based on measured soil data (N = 10309) for a reference depth of 30 cm for the hilly and mountainous area (10532 km<sup>2</sup>) of Emilia-Romagna (NE Italy). The methodology consists of: (i) definition of soil based eco-system services indicators (SES), based on available soil data and on societal demands; (ii) definition of appropriate indicators for SES potential supply and coding; and (iii) assessment and eventually mapping of soil based multiple ecosystem services at a 100 m resolution.

In this work we used spatial data to characterize and model the spatial heterogeneity of the following provisioning, supporting, and regulating SES resorting to Digital Soil Mapping (DSM) techniques: habitat for soil biodiversity, buffering capacity, carbon sequestration, food provision, biomass provision, erosion control, water regulation and water storage. In addition, an overall soil quality index based on selected SES is assessed and mapped. In order to explicitly take into account the spatial variability and the related uncertainty, and in order to exploit at best the available information, we: (i) realized a continuous coverage (on a 100 m regular grid) of basic soil properties (coarse fragments, sand, silt and clay fractions, organic carbon content, pH) via Quantile Random Forest (QRF) resorting to categorical and continuous covariates available over the entire area and (ii) derived the relevant soil properties (e.g. bulk density, porosity, retention properties, hydraulic conductivity) via locally calibrated pedotransfer functions.

Results are presented and analysed in terms of land use and pedolandsapes, to highlight how in the study area different mountain soils under different land use contribute to the potential supply of multiple ecosystem services, providing information for sustainable soil management and land planning.

### **"CAMPO RUPESTRE" – AN OLD CLIMATICALLY-BUFFERED INFERTILE MOUNTAIN RUPESTRIAN GRASSLAND (OCBIL) ENDANGERED BY THE EXPANSION OF IRON MINING ACTIVITIES**

M.G. LEITE, F.A.P. FERREIRA, A.R. KOZOVITS

Federal University of Ouro Preto, Ouro Preto, BRAZIL

Campos Rupestres (CR) are montane ecosystems, present at altitudes above 900m, which develop on rocky outcrops or shallow/nutrient-poor soils, mainly derived from the weathering of quartzites (QCR) and banded iron formations (FCR). They are ancient ecosystems, which developed under stable and very specific edaphoclimatic characteristics, whose soils and communities co-evolved over thousands of years, in other words, an OCBILs (Old, Climatically-Buffered Infertile Landscapes). CR are especially important in regions that house large reserves of iron ore, characterized by presenting different types of vegetation, with a great richness of species (many endemic), result of their isolated geographical position, on hilltops. Recent changes in environmental legislation of Minas Gerais State (Brazil) allow mining companies to compensate (exchange) half of their degraded area with the preservation of different vegetation complexes, if there is an "ecological equivalence", an equivalence that does not include edaphic parameters. Undoubtedly, the lithotypes (quartzites and banded iron formations) and their derived soils are determinants of the vegetation spectrum, distribution, and species richness of the CR. This research aimed to assist in the scientific understanding of this issue by analyzing geochemical data from soils in the Iron Quadrangle (QF), one of the few regions in the world that has CRQ and CRF with the same geological evolution. The results show that their soils have significantly different average concentrations and background values (FCR > iron and phosphorus; QCR > barium, copper, and potassium). Furthermore, the large standard deviation values obtained from elements concentrations analysis demonstrate the great heterogeneity of soils, even within the same ecosystem, CRQ or CRF (especially manganese). Maps of element concentrations isovalues reinforce these geochemical variations. Considering the differences observed, it becomes clear that these areas should not be automatically defined as equivalent and used for environmental compensation, running the risk of losing part of the ecosystem services they provide, considering especially that they are aquifers recharge areas and their importance to the sustainability of downstream regions.

## 4. Soil health in achieving the Sustainable Development Goals

### 4.11 133521 - Caring for mountain soils, the hidden key to climate change adaptation and SDGs: challenges, threats, success stories

#### FROM SOIL TO FORAGE IN ALPINE REGION: THREE-YEAR MONITORING OF NUTRIENT AND ORGANIC CARBON CIRCULARITY IN MOUNTAIN PERMANENT MEADOWS

D. BONA, D. BERTOLDI, S. SILVESTRI, G. IUSSIG

Fondazione Edmund Mach, San Michele all'Adige, ITALY

The study has been performed in an Alpine Valley. Dairy farms are essential for several reasons, including the impact on tourism. Part of the milk produced was collected and processed to produce quality dairy products, and their production protocol requires the use of fodder from the origin area. A consortium plant to treat the manure produced from local farms (115 KWe; feed with 19,000 tons/year of manure) has been built (2019). The liquid digestate (LD), after separation, returns to the permanent grasslands as fertilizers. The solid fraction is mainly delocalized to nearby vineyards. The work aims to monitor (from 2020 until 2022) the fertilizer used (LD), soil, and forage produced in three permanent grasslands at three different mowing dates (June, July, and September).

The LD had a low dry matter (DM) (4.66%) and volatile solids content (74.52%DM), while nutrient content was high (6.45%DM of N; 4.38%DM of Ammonia; 1.77 %DM of P; 9.13 %DM of K). The forage productivity ranged from 7.5 to 11.5 (tons/ha) with annual and seasonal (mow) differences. The nutritional properties of forages show differences among mow and years. The crude protein was about 12–22 (g/100 gDM), the total fibre was from 18–34%, the nitrate content was about 1000 mg/kgDM, and the phosphorus and potassium were 0.1–0.8% and 2.5–4.5%. The soils had a high content of SOM (6–16%) and good nutrient content. The higher value of N was 4 g/kg; exchangeable K values were always greater than 1000 mg/kg, and Mg values were between 400 and 800 mg/kg. Phosphorus has the year's greatest variability: 2020 showed the lowest values (around 200 mg/kg) while 2021, had the highest (between 600 and 900 mg/kg). The main output of this work is the monitoring of the nutrient and organic carbon circularity in mountain areas to improve farming practices for soil health maintenance, and for ensuring higher quality forage for livestock.

<sup>2</sup> CREA , Research Centre for Agriculture and Environment (CREA-AA), Roma, ITALY

<sup>3</sup> Maiella National Park, Majella Seed Bank, Sulmona, L'Aquila, ITALY

Intensive agricultural systems are facing significant challenges worldwide related to high production costs, land abandonment, and rural depopulation. In the Central Apennines of Italy, the sustainable land use policies adopted in the Maiella National Park retain biodiversity and protect soil from degradation by promoting agro-ecological practices linked with maintenance of indigenous crop varieties, self-production seeds, ecological infrastructures as dry stonewalls and huts for ancient pastoralism, and use of natural cover crops. The present study aimed to evaluate the effect of different cropping systems on biodiversity conservation and soil functionality, using a multidisciplinary approach. The study area is characterized by a compact limestone massif, rich in geosites with humid subtropical climate (Csa - Köppen classification). Nine sites are selected according to cropping systems: four heroic vineyards with different cultivars (i.e., Vedovella, Nero Antico, Pecorino, Trebbiano, Montepulciano), three olive orchards (Toccolana, Intosso, Rustica-Gentile) and two terraced high mountain meadows. To evaluate the soil functionality of the upper layer (10 cm), from 2021 to 2023, in Autumn, the soil was sampled to analyze water retention, pH, texture, electrical conductivity (EC), total organic carbon content (TOC), and edaphic microarthropods community using soil biological quality index (QBS-ar), abundances, and ecological indices. The main findings highlighted that land use affected soil characteristics (MANOVA,  $p < 0.001$ ; Tukey HSD test). Soils of meadow and old vineyards were fine-textured, with high TOC, neutral pH, and high moisture (GWC= 23%), while in olive orchards, soils were coarse-textured, with alkaline pH, and low moisture (GWC= 14%). High values of microarthropod density and richness were registered in soils of the three cropping systems. The QBS-ar index was very high in old vineyards (>200). In olive orchards, the tillage practice, although reduced, has a negative impact on the eu-edaphic arthropod community. Vineyards and olive orchards, which are integrated into their surroundings, turned out to be more resilient.

### SAVE THE LIFE-SUSTAINING MATTIC LAYER ON THE QINGHAI-TIBETAN PLATEAU

F. YANG, G. ZHANG

Institute of Soil Science, Chinese Academy of Sciences, Nanjing, CHINA

A striking phenomenon in alpine meadow on the Tibetan Plateau is the prevalent occurrence of a mat-like surface soil layer, which mantles most of the land wherever environment allows. This typically fine-textured, organic-rich and fairly resilient matic layer protect both topsoils and subsoils from erosion, which is fundamental for soils' multiple ecological functions and ecosystem services. The significance of this thin life-sustaining soil layer, however, has not been well acknowledged. From the perspective of earth surface system, we proposed that formation of the matic layer was a long-term interaction of biological, sedimentological and pedological processes, which renders the matic layer as a nonrenewable resource. We emphasized the ecological significance of the matic layer by highlighting its key role in providing multiple ecosystem services such as primary productivity, soil conservation, as well as water and carbon regulation. It is no exaggeration to say that without the matic layer, the ecosystem of the Tibetan Plateau is doomed to collapse. We appealed that more investigation and field monitoring should be conducted over a broad area to evaluate the impacts of climate changes and existing management practices on the health of the matic layer and call on the central and local government to prioritize the protection of the matic layer to safeguard the Tibetan ecological security barrier and to achieve sustainability of soils and other natural resources thus overall ecological and socioeconomic security in Tibetan Plateau.

<sup>2</sup> University of Milan, Department of Agricultural and Environmental Sciences, Milan, ITALY

Alpine grasslands are fragile ecosystems formed by plant species that have developed different adaptations to survive and reproduce in harsh environments. In alpine tundra, among the typical vegetation communities, two different types can be distinguished: the snowbed communities and the alpine *Carex curvula* grasslands. The first ones are characterised by a long snow cover duration (SCD), whereas the second ones have a shorter SCD. In both communities, snow plays a crucial role on soil carbon (C) and nitrogen (N) dynamics. In snowbed communities, soil moisture, snow melt-out day, and duration of soil freezing are the main drivers of soil C and N dynamics, with a potential influence on bacteria and fungi characterised by various genes coding for enzymes involved in the soil C and N cycling. Mountain regions are particularly affected by global warming, with a higher temperature and an earlier spring snowmelt. Consequently, a potential transition from snowbed communities towards alpine *Carex curvula* grasslands can be hypothesized, thus leading to a loss of biodiversity. For this reason, in 2016 a research activity was started in the LTER site Istituto Mosso (2650 – 2900 m a.s.l., NW Italian Alps), with the topsoil sampling in a snowbed community and in a *Carex curvula* grassland, during the snow-free season, to evaluate the dissolved organic carbon (DOC), nitrate and ammonium content in soil extracts. The topsoil temperature and gravimetric moisture are measured since 2016, while from the autumn 2023 also the collection of the soil solution was carried out. The results show that the soil ammonium and DOC in the alpine *Carex curvula* grassland are significantly higher than in the snowbed community, while there is no significant difference in the nitrate content. Under a changing climate, it is crucial to study the potential transition from snowbed communities towards alpine *Carex curvula* grasslands and the functioning of these ecosystems. Research supported by NBFC – University of Turin (DISAFA) - PNRR Project CN00000033

### 4.11 133521 - Caring for mountain soils, the hidden key to climate change adaptation and SDGs: challenges, threats, success stories

#### BLACK SOILS IN THE SOUTH SIDE OF THE ALPS: LARGE C STOCKS, STRONG WEATHERING DEGREE, GENETIC ISSUES

M. D'AMICO <sup>1</sup>, E. PINTALDI <sup>2</sup>, A. BENECH <sup>2</sup>, L. OKTABA <sup>3</sup>, B. KRUCZKOWSKA <sup>3</sup>, A. MASSEROLI <sup>1</sup>, L. ROSSI <sup>1</sup>, M. FREPPAZ <sup>2</sup>

<sup>1</sup> University of Milan, DISAA, Milano, ITALY

<sup>2</sup> University of Turin, DISAFA, Torino, ITALY

<sup>3</sup> Warsaw University of Life Sciences - Department Soil Sci, Warsaw, POLAND

Umbrisols are the most common soil type in the Southern side of the Alps, between Piedmont and the Lake District in Lombardy (NW-Italy) and Switzerland, particularly on silic substrates and glacial till but also on carbonates, if the soil is sufficiently deep. They are best developed on southward aspects, and below chestnut, beech forests or anthropogenic grasslands, at montane elevations. Many of these soils, particularly if developed on stable surfaces above the LGM trimline (i.e., the upper limit reached by glaciers), have 20-40 cm thick A horizons, with fine granular structure and abundant roots, overlying black sombric or sombric-like horizons (80-120 cm of depth) lacking biogenic aggregation, containing very few roots, and characterized by very low bulk densities, even <500 kg/m<sup>3</sup>. Carbon stocks are very high, up to 40 kg/m<sup>2</sup>. Egli et al. 2008 found the black horizons to be rich in charcoal, whereas Blaser et al., 1997 interpreted them as spodic horizons dominated by Al and organic matter (OM), and lacking Fe. However, some of their properties were not considered and their pedogenic interpretation is dubious.

To better characterize the black horizon, and particularly its OM properties (e.g., age, stability, chemical recalcitrance to decomposition, mineral stabilizing factors) five well-developed Umbrisols were sampled, in different locations in NW-Italy, between Torino metropolitan area (west) and Lake Como (east); soil micromorphological observations, and detailed analysis on mineral weathering and on OM characteristics were performed.

The results show that these soils developed during long periods of time, and podzolization is not a primary pedogenic process; strong mineral weathering, associated with temperate temperatures and high rainfall, has been able to release large quantities of Al from the parent materials, creating the conditions for Andosolization-like processes.

These soils are highly resistant to erosion and to degradation, due to the strong stabilizing effect of some ions, but their high C contents and old age make them precious and worth of protection.

### EXPLORING THE RELATIONSHIP BETWEEN SOIL BIODIVERSITY AND FOREST STAND ATTRIBUTES IN THE AUSTRIAN ALPS

O. BRADLEY, J. PÜSPÖK, J. OETTEL

Bundesforschungszentrum für Wald, Vienna, AUSTRIA

Soil biodiversity is essential to ecosystem services such as carbon sequestration and nutrient cycling but is threatened by mismanagement and global change. Austrian mountain forests are a global hotspot for soil biodiversity and carbon storage but are experiencing climate change at double the rate of lower altitude areas. Forest soil biodiversity is influenced by management-related drivers like forest stand structure, deadwood, and understory vegetation. However, these forest-specific drivers along with environmental variables have not been assessed in a combined monitoring program before.

AlpSoil is an ongoing project aiming to address these knowledge gaps with a twinned soil biodiversity study in the Northern Calcareous Alps and the siliceous Central Alps. We wish to integrate soil biodiversity surveys into existing forest biodiversity monitoring schemes at the Austrian Research Centre for Forests to test for drivers of soil community structure. Specifically, we address the following research questions: How is soil biodiversity influenced by 1) forest stand structure and 2) understory vegetation? 3) How does deadwood relate to soil organic carbon content and soil biodiversity? 4) What influences do pedological factors have on soil biodiversity?

Therefore, 60 study sites have been established on both calcareous and siliceous parent material in and around selected Austrian National Parks, spanning gradients of management intensity and altitude. Insect, bacterial, and fungal diversity in organic horizon and mineral soil has been measured with environmental DNA techniques alongside in-depth soil profile descriptions and forest stand structure, deadwood, and understory vegetation surveys. Additionally, soil organic carbon content, its bioavailability and soil pH have been measured.

Our results will provide a baseline for the status of soil biodiversity and will deliver information on important drivers of mountain forest soil biodiversity. We will inform stakeholders and the interested public about the importance of soil biodiversity for forest health and best practices to conserve it. Thereby, AlpSoil provides a key step for implementing soil biodiversity indicators into future country-wide forest biodiversity monitoring programs.

### MODIFIED SPENT COFFEE GROUNDS AND BIOCHAR REMEDIATION OF HEAVY METAL CONTAMINATED URBAN SOILS IN GLASGOW

P.W. MHLOPHE

University of Glasgow, Glasgow, UNITED KINGDOM

Heavy metals have long been a major source of soil pollution for both urban and agricultural soils. Different remediation methods have been implemented, some of which have proved successful, and others haven't. Earlier cleanup methods' efficacy was prioritised, while today's innovative methods are assessed for sustainability, cost, and multifunctionality. Due to the low cost of the biomass and its purpose as part of waste reuse, the use of spent coffee grounds for soil restoration is a great example of a sustainable remediation strategy. It has been demonstrated that using raw coffee grounds and biochar to amend and improve soil is successful. The purpose of this study is to investigate how used coffee grounds can help soils immobilise heavy metals. Used coffee grounds will be utilised in two ways: half will be converted into Biochar (by pyrolysis at 550°C), while the other half will be used raw. Both will undergo additional hydrogen peroxide modification after being pyrolyzed to produce biochar. Raw SCG, modified SCG, pristine Biochar, and modified Biochar will be the four main treatments. Each of them will be divided into application rates of 5% and 10%, with each treatment being repeated five times. 500g of contaminated soil will be combined with these treatments in a plastic column. The treatments will spend six weeks in a temperature-controlled space, receiving regular irrigations of distilled or deionized water, with the leachate being collected and tested. The top of the column will be covered, gas fluxes will be measured. After six weeks of growth, bok choy plants will be examined for the presence of heavy metals to determine the impact of the treatments on the bioavailability of heavy metals. Heavy metal concentrations in the soil/SCG/Biochar combinations will also be analysed.

P/S Final poster will have some results

### EXPLORING ORGANIC HIGH TUNNEL SOIL HEALTH UNDER WINTER COVER CROP ROTATIONS

H. WALSH <sup>1</sup>, J. GROSSMAN <sup>2</sup>, A. FERNANDEZ <sup>3</sup>, A. MCCUNE <sup>4</sup>

<sup>1</sup> University of Minnesota - Twin Cities, Dept. of Soil, Water, & Climate, Saint Paul, MN, USA

<sup>2</sup> University of Minnesota - Twin Cities, Dept. of Horticulture, Saint Paul, MN, USA

<sup>3</sup> University of Minnesota - Twin Cities, Dept. of Horticulture, Saint Paul, MN, USA

<sup>4</sup> University of Minnesota - Twin Cities, Dept. of Horticulture, Saint Paul, MN, USA

High tunnels are semi-permanent structures used in temperate climates to increase vegetable production by leveraging shoulder seasons when open fields may be inaccessible due to cold weather or spring flooding. They have become increasingly popular with the advent of cost-share programs through the NRCS. However, HTs are associated with soil degradation through nutrient buildup, compaction, and yield losses. Organic high tunnels differ significantly from the open field due to a lack of natural rainfall, uneven soil wetting, and temperature differentials. Planting winter legume cover crops in rotation with summer vegetables is an emerging strategy to mitigate possible adverse effects. Yet, there is limited knowledge of how the planting and termination time of winter cover crops impact soil health and cash crop yield. Productivity tradeoffs are expected, as early fall cover crop planting and late spring termination may interfere with lucrative cash crop production windows. Conversely, extending the growth period of the cover crop may increase its potential to provide soil-enhancing biomass. This research evaluates the degree to which fall planting and spring termination time of two winter cover crops, hairy vetch (*Vicia villosa* Roth) and Austrian winter pea (*Pisum sativum* L.), affects 1) cover crop biomass, 2) pepper yield, 3) active soil organic matter pools (POX-C), and 4) plant-available soil nitrogen (N) in organically managed high tunnels. Biomass samples were collected pre-termination in spring 2022 and 2023. Soil samples were collected two weeks post-cover crop termination. Early-planted peas produced the most biomass in both years, while late-planted vetch produced the least. Termination time had varying effects, suggesting that initial fall biomass production is essential to total biomass production. Soil-N, POX-C, and cash crop yield data from both years are currently under analysis. This data will help farmers make informed decisions regarding the tradeoffs of planting winter cover crops in HTs.

## 4. Soil health in achieving the Sustainable Development Goals 4.12 133530 - Soil degradation control, remediation and reclamation

### RHODOTORULA YEASTS - POTENTIAL TOOLS FOR BIOREMEDIATION OF HYDROCARBON AND OIL CONTAMINATED SOILS

O. CSUTAK<sup>1</sup>, V.M. CORBU<sup>1,2</sup>

<sup>1</sup> University of Bucharest, Faculty of Biology, Department of Genetics, Bucharest, ROMANIA

<sup>2</sup> University of Bucharest, Research Institute of the University of Bucharest (ICUB), Bucharest, ROMANIA

During past decades, the industrial and household wastes became a growing threat for the environmental health and balance. Bioremediation technologies based on metabolic intrinsic abilities of microorganisms to degrade organic and inorganic contaminants, represent an ecologic alternative for decontamination of polluted areas.

The yeast genus *Rhodotorula* comprises species able to assimilate a hydrocarbons and vegetable oils and to convert them into eco-friendly biocompounds. Our work focuses on three yeast strains from oil-polluted soil: *Rhodotorula mucilaginosa* CMGB-G1, *Rhodotorula glutinis* CMGB189 and *Rhodotorula mucilaginosa* CMGB188. The cell growth was monitored over a week on yeast peptone (YP) medium with 1% n-hexadecane, petroleum and fried sunflower oil (single used, reused). The *R. mucilaginosa* strains preferred the sunflower oil, CMGB-G1 showing an impressive growth within the first 48 hours on reused fried oil. *R. glutinis* CMGB189 grew on hydrocarbons, but fried oil was also assimilated with a slow ascending slope during the whole experiment. Microscopy observations revealed interactions between the yeast cells and the hydrophobic substrates and presence of lipid droplets.

Biosurfactant synthesis was evaluated in the presence of fried oil, by calculating the emulsification index (E24%). Best biosurfactant producers were *R. glutinis* CMGB189 (49% on reused, 43% on single used fried oil after three days) and *R. mucilaginosa* CMGB-G1 (42% on reused fried oil after three days, 45% on single used fried oil after six days).

The MATH values suggested that the *R. mucilaginosa* strains incorporate the n-hexadecane by direct cell-droplets interactions, the assimilation mechanism of *R. glutinis* CMGB189 relying mostly on biosurfactant synthesis.

The PCR-RAPD biodiversity studies using seven primers (OPA01, OPA11, OPA18, OPE18, OPH15, OPH19; M13) recommended OPE18 as molecular marker for determination of phylogenetic relatedness based on strain origin of isolation, respectively, OPA18 and OPH19 for identification of interspecific polymorphism.

In conclusion, our three *Rhodotorula* strains represent promising candidates for the development of strategies aimed to combat soil pollution and to reintegrate degraded soils for a sustainable agriculture.

**Keywords:** *Rhodotorula*, polluted soil, bioremediation, hydrophobic wastes, sustainable agriculture

<sup>3</sup> Warsaw University of Life Sciences - SGGW, Warsaw, POLAND

<sup>4</sup> Warsaw University of Life Sciences - SGGW, Warsaw, POLAND

<sup>5</sup> Technische Universität Braunschweig, Braunschweig, GERMANY

The study aimed to evaluate trace elements dispersal in the opencast lignite mining zone using Scots pine bark as a passive sampler. The study was performed near Belchatów (Poland), where lignite opencast mining began in the 1940s and continues to the present day. Lignite opencast mining, its transport, combustion in power station, heaps, and fly ash settlers should be indicated as major sources of contaminants in this area. The study covered 815 km<sup>2</sup>, where the above-mentioned objects were centrally located. Scots pine bark was collected from 100 locations. The age of the trees ranged from 28 to 131 years, and their diameter from 20 to 44 cm. Bark samples were dried at 65°C and milled into powder. The contents of As, Ad, Co, Cr, Cu, Mn, Ni, Pb, Sr, V, and Zn were determined by ICP-OES (Avio 200, Perkin Elmer) prior samples microwave digestion in a mixture of 65% HNO<sub>3</sub> and 38% HCl, whereas S by dry combustion (Vario MacroCube, Elementar). Results of the studies clearly show the large importance of lignite opencast mining as a source of trace elements in the surrounding environment. Their concentrations in pine bark strongly varied, reaching the highest values usually in the vicinity of emission sources. However, in more detail, spatial distribution patterns differed among elements. Some of them (As, Cd, Cr, Mn, Pb, Zn) were strongly affected by predominant wind directions, thus reaching the highest contents in the E and SE locations from emission sources. Another elements (Cu, Co, Sr, V) occurred at the highest amounts directly near the power plant station. This is probably due to their association with lignite dust. Generally, our study demonstrates the large role of lignite opencast mining and processing as a source of environmental contamination with trace elements. However, dispersal of these substances is a function of elements and environmental factors. Moreover, our study confirmed the relevance of pine bark as a sensitive bio-indicator of environmental pollution.

### RESISTANCE OF SOIL TO PENETRATION AS A PARAMETER INDICATOR OF SUBSOLATION IN CROP AREAS OF SUGAR CANE

L.C. LOPES FILHO, J. BELÉM DE MOURA

Faculdade Evangélica de Goianésia, Goianésia, BRAZIL

Sugarcane is a very important economic crop that relies heavily on agricultural machinery, which contributes to soil compaction and a consequent decline in productivity. Subsoiling operation reduces the problems caused by compression; however, it is necessary to know its location and intensity. Accordingly, the aim of this work is to present a compression diagnostic method based on soil resistance to penetration as the parameter that indicates need for intervention in the subsoil. Measurements of penetration resistance was carried out in areas of sugarcane, located in the municipalities of Goianésia, Barro Alto and Santa Isabel, in the Brazilian state of Goiás. The Falker penetrometer (PLG 1020) was used, adjusted to a maximum depth of 40 cm and adopted as a critical resistance value of 4.0 MPa. The data were interpolated using kriging and adjusted in AutoCAD 2013 (Autodesk). The methodology proved effective in areas of compacted soil, and the surface layer had less resistance. The reduction in soil preparation was 96.54% and when considering the topographic adjustments, the reduction was 74.07%, showing the viability and importance of the diagnosis to show the proper management.

Figure 1. Resistance to root penetration (MPa) in soil cultivated with sugarcane in areas with compaction less than 4 MPa (A) and in areas with compaction greater than 4 MPa (B).

## 4. Soil health in achieving the Sustainable Development Goals 4.12 133530 - Soil degradation control, remediation and reclamation

### IMPACTS OF SIMULATED EROSION AND FERTILIZATION USE ON SOIL QUALITY AND CORN YIELD IN NORTHEASTERN BLACK SOIL REGION

Y. LI <sup>1</sup>, Z. WANG <sup>2</sup>, X. ZHANG <sup>1</sup>

<sup>1</sup> Institute of Soil and Water Conservation, Northwest A&F University, Yangling, CHINA

<sup>2</sup> Faculty of Geographical Science, Beijing Normal University, Beijing, CHINA

Soil erosion is a major factor causing soil thinning and crop productivity reduction in the Northeast black soil region, China, but assessing its effect quantitatively is lacking. Hence, a two-factor completely randomized block design with simulated erosion depth (8 levels of 0, 10, 20, 30, 40, 50, 60 and 70 cm) and fertilization (no fertilization and fertilization) was set up. In 2022, a series of soil physicochemical [bulk density (BD), soil water content (SWC), clay content, pH, soil organic C (SOC), alkali-hydrolyzed N (AN), Olsen-P (AP) and available K (AK)] and biological properties [microbial biomass C and N (MBC, MBN), urease, catalase, beta-glucosidase (glucosidase), cellulase activities] in 0-20 cm and corn yield were measured. The results showed that:

1) Soil clay content, SOC, AN, AP, MBC and cellulase activities decreased significantly with the increased erosion depth, while BD and AK increased significantly. Fertilization significantly decreased soil BD, pH and AK, and increased clay content, SOC, AN and AP, fertilization also significantly increased the activities of urease, glucosidase, cellulase, but decreased catalase activities.

2) Simulated erosion resulted in significant reductions in soil quality and corn yield. The decrease of soil quality and yield mainly occurred before the erosion depth of 40 cm, and fertilization mainly improved soil quality and yield within this range.

3) The main factors affecting soil quality under simulated erosion were AN, MBN, and urease activity for the no fertilization treatment, and AP, MBC, cellulase and glucosidase activities for the fertilization treatment, and the fertilizer application shifted the soil quality from N-limitation to co-limitation of C and P. The main factors affecting corn yield under simulated erosion were AN for the no fertilization treatment and AP for the fertilization treatment, and yield limitation shifted from N limitation to P limitation.

These results deepen the relationship between soil erosion-soil quality-productivity in black soil, and may be useful for evaluating the long-term evolution process of black soil quality.

**Keywords:** Black soil, Simulated erosion, Fertilization, Soil quality, Corn yield

## 4. Soil health in achieving the Sustainable Development Goals 4.12 133530 - Soil degradation control, remediation and reclamation

### GEOCHEMICAL SIGNATURES OF YTTRIUM, THORIUM, NIOBIUM, RUBIDIUM AND ZIRCONIUM IN SELECTED SOILS FROM CROATIA

A. PERCIN, I. SESTAK, I. DUGAN, M. GALIC, M. MESIC, I. KISIC, Z. ZGORELEC

University of Zagreb Faculty of agriculture, Division for Agroecology, Department of General Agronomy, Zagreb, CROATIA

In most scientific research, the geochemical characterization of soil is focused on determination the content of potentially toxic metals (Cu, Mn, Cr, Ni, Pb and Cd), and to a lesser extent on certain rare elements such as yttrium (Y), thorium (Th), niobium (Nb), rubidium (Rb) and zirconium (Zr). These elements are a key part of today's modern industry which can contribute to increased accumulation of these elements in the soil. The aim of this study was to determine the variability of total concentrations of Y, Th, Nb, Rb and Zr in selected soils from continental and costal part of Croatia regarding the different types of land use. Research was based on 33 surface composite soil samples collected at 13 locations in Croatia. The samples differed according to soil type, land use, applied mineral and organic nitrogen fertilization, and climatic condition at each specific location. The detection and quantification of Y, Th, Nb, Rb and Zr was performed in duplicate using the handheld Vanta C (Olympus) XRF analyser according to the loose powder method and "point and shoot" technique. The results reveal that Croatians soils in average contained  $31.2 \pm 6.8$  mg Y/kg,  $7.8 \pm 4.5$  mg Th/kg,  $18.2 \pm 7.0$  mg Nb/kg,  $100.8 \pm 26.1$  mg Rb/kg and  $283.3 \pm 116.3$  mg Zr/kg. Significantly the highest contents of rubidium ( $116.8 \pm 16.0$  mg/kg), niobium ( $20.2 \pm 6.2$  mg/kg) and thorium ( $10.3 \pm 4.8$  mg/kg) were recorded in meadow soils, while the lowest amounts were quantified in soil from ski slope ( $42.5 \pm 0.7$  mg Rb/kg,  $6.5 \pm 2.1$  mg Nb/kg,  $4.0 \pm 0.1$  Th/kg). Yttrium content in soils according to different land use declines in the following order: ski slope ( $33.5 \pm 0.7$  mg/kg) > crop production ( $32.4 \pm 7.0$  mg/kg) > meadow ( $32.3 \pm 1.4$  mg/kg) > forest ( $32.0 \pm 9.5$  mg/kg) > apple orchard ( $26.8 \pm 6.3$  mg/kg) > city road ( $25.8 \pm 3.8$  mg/kg). Accumulated amount of zirconium significantly varied from  $158.8 \pm 21.9$  mg/kg in soils near city roads to  $333.0 \pm 97.8$  mg/kg in arable soils.

## 4. Soil health in achieving the Sustainable Development Goals 4.12 133530 - Soil degradation control, remediation and reclamation

### CHANGES OF THE SOIL ERODIBILITY FACTOR IN THE LONG-TERM EXPERIMENT ON CHERNOZEM

S. SEREMESIC <sup>1</sup>, V. CIRIC <sup>1</sup>, B. VOJNOV <sup>1</sup>, S. MILIC <sup>2</sup>, B. PEJIC <sup>1</sup>, M. ZIVANOV <sup>2</sup>, D. RADOVANOVIC <sup>1</sup>

<sup>1</sup> University of Novi Sad, Faculty of Agriculture, Novi Sad, SERBIA

<sup>2</sup> Institute of Field and Vegetable Crops, Novi Sad, SERBIA

Soil erodibility is the most widespread form of soil degradation in Europe. However, information on the intensity and susceptibility to erosion of arable soil is lacking for Serbia. Therefore, we assess the K-factor erodibility nomograph values (Wischmeier and Smith, 1978) in the long-term experiment in the semi-arid region of northern Serbia. The erodibility between the initial state in 1970 and the current 2023 was compared and assessed to estimate the changes associated with management practices and climatic changes. The sampling was conducted on the Chernozem soil subtype on loess at the Experimental Field of the Institute of Field and Vegetable Crops in Novi Sad. Soil organic matter (%) and soil texture were determined in 0-30 cm soil depth of the 6 cropping systems that include winter wheat, maize and soybean. Soil tillage was based on moldboard plowing and field cultivator with fertilization following the balanced method of plant requirements. Our findings indicate an average of 0.0187 t ha h ha<sup>-1</sup> MJ<sup>-1</sup> mm<sup>-1</sup> in 1970 which is lower compared to 0.0226 t ha h ha<sup>-1</sup> MJ<sup>-1</sup> mm<sup>-1</sup> in 2023. That represents the difference of the 0.0039 t ha h ha<sup>-1</sup> MJ<sup>-1</sup> mm<sup>-1</sup> for over 50 years. Higher susceptibility for erosion in 1970 was found in the winter wheat monoculture and lower at 3-year crop rotation (maize-winter wheat-soybean). In 2023 greater susceptibility to erosion was also found at monoculture but lower at 2-year rotation (maize-winter wheat). Winter wheat monoculture showed a pronounced exposure to all types of erosion and degradation. This can be explained by the differences in soil cover during the year, crop residue amount in cropping systems, and the increased number of heavy rain occurrences. Results indicated a general trend of continued negative anthropogenic effects on increased erosion and the higher vulnerability of agroecosystems.

### PLANT GROWTH PROMOTING BACTERIA IN ASSISTED HEAVY METAL PHYTOREMEDIATION

L. CAVALCA, A. MELZI, S. ZECCHIN, S. MONDAL

Università degli Studi di Milano, Dipartimento di Scienze per gli Alimenti, la Nutrizione e l'Ambiente-DeFENS, Milano, ITALY

Heavy metals affect agricultural soils and mining areas and are of particular threat when they are present in bioavailable forms. Such a condition can be displayed for example in rice paddy soils, in natural or constructed wetlands and in acid mine drainage.

This study focuses on the characterization of a collection of bacterial isolates for multiple plant growth promoting (PGP) activities and heavy metal (Ni, Cu, Cr, Zn) resistance. The strains *Aeromonas media* MORI-53, *Serratia plymuthica* As3-5a(5), *Rhodococcus qingshengii* SC26 and *Pseudomonas koreensis* 69RS showed PGP activities (IAA and siderophore production, ACCD activity, P solubilization and N<sub>2</sub> fixation) also in the presence of heavy metals, resulting to be interesting strains. The characterization of heavy metal resistance revealed that *A. media* strain MORI-53 was resistant to 150 mM Zn(II) in growing conditions, *S. plymuthica* strain As3-5a(5) was able to adsorb 91.5% of Cu(II) and 40% Ni(II) by adsorption processes mediated by EPS, and *R. qingshengii* SC26 was able to reduce up to 98% of 50 mg L<sup>-1</sup> Cr(VI) into its less toxic form Cr(III) during exponential growth phase. For this strain a NADP-dependent oxidoreductase activity was evidenced, and it was linked to the presence of the metal. The PGP activities of the strains were assessed on *Oryza sativa* (L.), used as model plant able to accumulate high concentration of heavy metals in submerged conditions.

Rice plant growth pouches assays, conducted under gnotobiotic conditions, exhibited a 50% increase in root and plant biomass as well as seed germination of inoculated plant seedlings compared to uninoculated control plants.

The present observations showed that the bacterial strains used in this study could relief plants against the inhibitory effects of Ni, Cu, Cr and Zn, probably due to the production of IAA, siderophores and ACCD activity. On-going experiments will determine plant heavy metal extraction by rice in submerged soils in the presence of the selected strains.

### EFFECT OF BIOCHAR ON HEAVY METAL SOLUBILITY AND SPECIATION IN SOILS AROUND MAJOR METALLURGICAL PLANTS IN BULGARIA

I. ATANASSOVA, M. STOYKOVA, L. NENOVA, T. SIMEONOVA, M. BENKOVA

Nikola Poushkarov Institute of Soil Science, Agrotechnologies and Plant Protection, Sofia, BULGARIA

The effects of biochar on heavy metals concentrations and soil properties in the vicinity of Aurubis-Pirdop Cu smelter and the former metallurgical steel plant were studied. Maximum permissible levels were exceeded for Cu 319-2645 mg/kg and from 92-234 mg/kg for Pb around the Aurubis-Pirdop Cu-smelter. Lead Pb (899 mg/kg) exceeded maximum permissible concentrations, regulated by Bulgarian legislation between 2 and 15 times, arsenic (As), between 3 and 6 times for the soils (pH 7-8) around the former steel plant. Incubation experiments were performed with different rates of biochar (BC), 1, 5, 10 and 20 % in a Climatic Chamber with Phytotron System. Metals were measured in water extracts and speciation was performed by Visual Minteq. For the acidic Cu-contaminated soils incubation time and BC rates led to a total decrease of Cu and Pb concentrations. In these soils, dissolved organic carbon (DOC) and pH increased with BC incubation rates. Ion speciation in the non-treated acidic soils was represented by the free  $M^{n+}$  ions, while with increasing incubation time and BC rates, FA2M and M-FA gel fraction species were predominant. In the acidic soils the total soluble Cu concentration decreased by ~ 70%, while free Cu species concentrations decreased to ~ 3.7%. For the soils around the steel plant there was an increase of soluble concentrations of Fe and Mn, which was attributed to elevated levels of DOC and the presence of FA2FeOH, FAMn+2G complexes. Lead was not significantly affected by the BC rate. Biochar incorporation has a positive effect both on Cu, Pb and other metals concentrations and on metal speciation in the acidic soils, however in the slightly alkaline soils around the steel plant, DOC complexation of Fe and Mn was accompanied with an overall increase of soluble concentrations, thus indicating that biochar might not produce a positive effect on major heavy metals immobilisation in neutral and alkaline soils.

### ISOLATION AND IDENTIFICATION OF HIGH EFFICIENCY DIESEL DEGRADATION STRAIN IN OIL CONTAMINATED SOIL

Y. XIE

Nanjing Institute of Environmental Sciences, MEE, Nanjing, CHINA

In order to screen different characteristics of high-efficiency diesel degrading strains and study their degrading mechanism in different environmental condition, 7 high-efficiency diesel degrading bacterial strains were isolated from the sludge sediments in Nanjing Yangzi Petrochemical Plant. The results showed that the degradation rates of strains J-3 exceeded 50.0% of diesel.

The degradation efficiency of diesel and the degradation mechanism of strain J-3 were studied by hydroponic and soil culture methods combined with GC-MS and genome comparison techniques. The results showed that the strain could efficiently grow using diesel as its sole carbon and energy source, producing surfactant, and having stable emulsifying properties and reducing liquid surface tension. It could produce surfactant, which showed it has a stable emulsifying property and the ability to reduce liquid surface tension. The degradation efficiency of diesel under the optimal growth conditions was 62.0%. Based on the whole-genome DNA sequence analysis of the strain J-3, two genes associated with alkane oxidation were found, namely *alkB*, an alkane hydroxylase gene, and *almA*, a Long-chain alkane monooxygenase gene. These two oxidase genes may play a role in the degradation of diesel oil by strain J-3.

In addition, when the highly degraded strain J-3 and the currently well-researched strain J-7 (*Bacillus*) were applied to the soil remediation test of diesel pollution, the degradation efficiency of diesel were studied by Research on single bacteria and the coexistence of single bacteria and indigenous microorganisms. It was found that under the conditions of this experiment, the indigenous microorganism played a major role in the degradation of diesel fuel in soil. Under different control treatments, the degradation ability of the strain J-3 to diesel in soil was higher than that of J-7, indicating that the strain J-3 was a high-efficiency diesel degradation bacterial strain. The strain J-3 could be well used for growth in both water and soil, and could be applied to the actual bioremediation project of diesel pollution.

<sup>3</sup> AON Impact Forecasting, Prague, Prague, CZECH REPUBLIC

<sup>4</sup> Independent botanist, Prague

#### Abstract

Forest benefits in mountain catchments consider namely the reduction of drainage network connectivity, stabilization of slopes, and protection of soil and water quality. In Europe, approximately 70% of forests are controlled by management plans, and 25% are registered as forests of non-wood services with priorities in soil and water conservation. However, with commercial forestry practices, this role of forests can deteriorate. In the Czech Republic, mountain watersheds are mostly forested with dominant plantations of Norway spruce. The acid atmospheric deposition culminated there in the 1980s followed by the forest dieback and clear-cut. This paper aims to analyze the effects of acid rain and forest practices on the soil-vegetation complex in the headwaters of the Jizera Mountains. From 1982-2020, the environmental impacts of the acid load and consequent clear-cutting of spruce stands were studied in the Jizerka experimental catchment. The significant drop in tree radial growth was detected with the rising SO<sub>2</sub> concentrations in the air, and, the loss of soil corresponded particularly with commercial forestry. Skidding the timber by wheeled tractors caused 10.3 km<sup>-1</sup> of skid trails and the drainage density increased from 1.45 to 7.55 km<sup>-1</sup>. On the harvested runoff plots, not affected by skid trails, the loss of soil 0.007 - 0.014 mm year<sup>-1</sup> was comparable with undisturbed forests. However, the eroded soil in skid trails reached 6.17 mm by harvesting 23,882 m<sup>3</sup> of timber. At the catchment outlet, sediment yield reached 25% of the soil eroded. After the timber harvest, grass communities became dominant and prolonged the forest regrowth. On the whole, 156 phytosociological relevés were investigated to analyze the herb layer development: this monitoring included 53 deep, 33 medium, and 38 shallow rills, 15 plots with dead spruce stands, and 17 clear-cut spots. Using the information on higher plants only, the percentage cover of herb layer and species richness were analyzed. Natural regeneration of erosion rills was supported particularly by the development of herbaceous vegetation.

### ENERGY PRODUCTIVITY OF POACEAE USED IN THE PHYTORREMEDICATION OF METALS IN SOIL FROM TANNERY INDUSTRIALS

M. PORTO MUNIZ <sup>1</sup>, W. MOZENA LEANDRO <sup>1</sup>, M. RORIS SEVERINO <sup>2</sup>, P. BATISTA PASSOS <sup>1</sup>, J.P. VILELA DE CASTRO <sup>1</sup>, C. BROM AKI DE OLIVEIRA <sup>1</sup>

<sup>1</sup> Federal University of Goiás (UFG) - School of Agronomy - Department of Soils., Goiânia/Goiás, BRAZIL

<sup>2</sup> Federal University of Goiás (UFG) - Faculty of Science and Technology, Aparecida de Goiânia/Goiás, BRAZIL

Leather production has significant economic importance in the State of Goiás. Such activity can result in land being contaminated with potentially toxic metals such as chromium (Cr) and nickel (Ni). Phytoremediation is a bioremediation technique that consists of the direct use of plants for the transfer or stabilization of all potentially toxic metals in polluted soils. Bioenergy is a sustainable energy source option, however, it is often criticized for indirect changes in land use, due to a lack of high-quality agricultural land and competing with food production. At the same time, contaminated areas remain unused. The aim of the work was to evaluate the performance of plants from the Poaceae family in the phytoremediation and energy productivity of a soil with the presence of potentially toxic metals. The experiment was carried out in an urban perimeter area in the municipality of Anicuns-GO, Brazil, located at a tannery sludge spill site. The tannery was deactivated and there was no recovery of the degraded area, and there is the presence of the potentially toxic metals chromium (Cr) and nickel (Ni). The experimental design was in randomized blocks with 5 treatments and 4 replications. The treatments were composed of: sugar cane (*Saccharum officinarum*), energy cane (*Saccharum robustum*), purple grass (*Pennisetum purpureum* cv Roxo), capiaçu grass (*Pennisetum purpureum* cv. BRS Capiáçu) and spontaneous plants. The plants were cut after 12 months of cultivation. Green biomass was analyzed; dry biomass; metal content (chromium and nickel) in soil, biomass and extraction; and energy productivity. The data were subjected to analysis of variance, Tukey test and Pearson correlation coefficient. The biomass production and energy productivity of the plants were not harmed by the high levels of Cr and Ni, and followed the order capiaçu grass > purple grass > sugar cane > energy cane > spontaneous plants. There was a high Pearson correlation (greater than 0.7) between biomass production and energy productivity with Cr extraction.

### MINESOIL RESTORATION WITH PERENNIAL GRASSES IN SOUTHERN BRAZIL: CANONICAL CORRELATIONS BETWEEN SOIL BIOLOGICAL, CHEMICAL AND PHYSICAL ATTRIBUTES

M. BERTASO DE GARCIA FERNAND <sup>1</sup>, L. STUMPF <sup>1</sup>, N. BRÜGGEMANN <sup>2</sup>, O. DOS ANJOS LEAL <sup>2</sup>

<sup>1</sup> Federal University of Pelotas, Soil and Water Management and Conservation Program, Pelotas, Brazil, Pelotas, BRAZIL

<sup>2</sup> Forschungszentrum Jülich GmbH, Institute of Bio- and Geosciences - Agrosphere (IBG-3), Jülich, Germany, Jülich, GERMANY

The Candiota Mine in Southern Brazil is the country's largest coal reserve. The re-establishment of vegetation and living organisms in minesoils is usually hampered by excessive soil compaction, eventual acidity, and depletion of soil organic matter. We aimed to evaluate the abundance of soil mesofauna organisms and their association with minesoil physical and chemical attributes through canonical correlation analysis as affected by revegetation species.

In 2007, a randomized block design experiment was installed in the Candiota Mine minesoil with five treatments: *Hemarthria altissima*, *Cynodon dactylon*, *Panicum maximum*, *Urochloa humidicola* and *Urochloa brizantha*. After 14.6 years, soil bulk density (BD), porosity, and total organic carbon (TOC) content were evaluated (0 to 10 cm layer). Sampling of fauna inhabiting the interior of the minesoil occurred in two steps: two steel cylinders (summing up 169.4 cm<sup>3</sup>) were used at each plot (20 m<sup>2</sup>) to obtain soil cores (0-10 cm layer), then the Tullgren Extraction Funnel was used to collect fauna from soil core. The holes left by the cores were used to install 2 pitfall traps (for 7 days) per plot (summing up 16.94 cm<sup>2</sup>) for sampling fauna inhabiting the litter-soil interface. Fauna data is reported as the total number of individuals collected (soil interior + litter-soil interface). These data were subjected to canonical correlation analysis (CCA).

In total, 13,198 fauna organisms (9 taxonomic groups) were found in the experimental plots, predominantly mites and springtails. The abundance of mites ranged from 1,303 in *H. altissima* to 2,607 in *U. brizantha*, and that of springtails from 393 in *P. maximum* to 678 in *C. dactylon*.

Axis 1 and 2 of the CCA explained 87.3 and 12.7% of the variation, respectively. The correlation between TOC content and total porosity and macroporosity was more prominent in *U. brizantha*, likely due to its higher root density. Overall, the CCA revealed incipient associations between soil mesofauna and physical attributes and TOC.

### AN APPROACH FOR DETERMINING THE MINIMUM DATA SET FOR SOIL CONTAMINATION ASSESSMENT: AN APPLICATION IN A FORMER OUTDOOR SHOOTING RANGE (OSR) IN SOUTHERN ITALY

C. PERRECA <sup>1</sup>, G. BUTTAFUOCO <sup>2</sup>, F. TERRIBILE <sup>1,3</sup>, S. VINGIANI <sup>1,3</sup>

<sup>1</sup> University Federico II of Naples, Department of Agricultural Sciences, Portici(NA), ITALY

<sup>2</sup> National Research Council of Italy, Institute for Agriculture and Forestry Systems in the Mediterranean, Rende (CS), ITALY

<sup>3</sup> University Federico II of Naples, CRISP, Interdepartmental Research Centre on the Earth Critical Zone, Portici(NA), ITALY

Outdoor shooting ranges (OSRs) are recreational facilities attracting the interest of several millions of people worldwide, but if after the end of activities the land is used for recreational or agricultural purposes, soil contamination can pose a serious threat to human health. In this framework, a research study funded by the Italian Ministry of University and Research (MUR) was carried out in soils of an OSR of 38500 m<sup>2</sup> in southern Italy and aimed to determine the minimum data set for soil contamination. Different soil proximal sensing and laboratory data were collected, but this study was focused on three potentially toxic elements (PTEs), including As, Pb, and Sb measured by portable X-ray fluorescence spectrometer (pXRF) in soil samples (0-15 and 15-30 cm-depth) at 174 nodes of a regular grid (15 x 15 m) and apparent soil electrical conductivity (ECa) measured by electro-magnetic induction (EMI) along parallel transects 15 m apart. Since ECa was a more densely measured covariate than ECa, was used as external drift to improve the PTEs predictions. The PTEs data set was randomly split into a calculation (80%) and validation (20%) set to assess the effect of the number of samples on the predictive performance of the PTEs, four calculation subsets with sample size varying from 35 to 139 were created. Each subset selection was replicated three times to evaluate the robustness of the approach. PTEs data were submitted to an isometric log-ratio (ilr) transformation because As, Pb, and Sb are compositional data and, therefore, parts of a whole that constitute the soil and are not free to vary independently of the others. Kriging with external drift (KED) was used to incorporate the densely sampled ECa secondary data. The accuracy of prediction was assessed by the mean error, the root mean square error of prediction (RMSEP) and the ratio of the interquartile distance (RPIQ).

### CAN BIOCHAR IMPROVE THE BIOREMEDIATION OF ARABLE SOILS DEGRADED BY INTENSIVE MANAGEMENT?

J.A. SILES MARTOS, M. PATIÑO GARCÍA, J.L. MORENO ORTEGO

CSIC-CEBAS, MURCIA, SPAIN

Soil is an essential and limited resource, and its degradation through different processes poses a threat to its ecological functions, as well as to the sustainable development of agricultural activity. Specifically, in agricultural areas with intensive production of irrigated crops and with an arid and semi-arid climate, the use of desalinated water of marine origin and reclaimed water of residual origin results in the accumulation of boron (B) in soil and crops. Moreover, the intensive use of pesticides and fertilizers contaminates the soil and water with inorganic and organic chemical compounds, leading to a deterioration in soil quality and a reduction in production, rendering agricultural activity unsustainable. Soil bioremediation technologies have become a viable approach that promotes the transition from conventional intensive production agrosystems to more sustainable ecological production systems. On the other hand, the reuse of reconditioned organic waste for use as soil amendments in agriculture has been proposed as essential for the recovery of degraded soils. Biochar can serve as beneficial organic soil amendment while functioning as a catalyst for the bioremediation process of contaminated soils, facilitating the transformation, adsorption, and biodegradation of contaminants. This study aims to evaluate the bioremediation of contaminated agricultural soils at lab scale, integrating various strategies such as the application of biochar, composts and plant extracts. Specifically, the study explores the capacity of biochar, both independently and in combination with a compost and a plant extract, in the one hand, to facilitate the biodegradation by microorganisms of an herbicide, such as pendimethalin, and, to reduce the B concentration in the soil solution. Additionally, the study examines whether this bioremediation strategy enhances the health and quality of the soil by monitoring several soil enzyme activities (beta-glucosidase, phosphatase and urease activity) and the microbial community composition in two different degraded soils. The poster presents several preliminary results indicating the evolution of some chemical, biochemical and microbiological properties of two degraded soils throughout 180-day incubation experiment.

**IMPACT OF PAVED AND UNPAVED ROADS ON SOIL PROPERTIES IN MARIGAT, BARINGO COUNTY, KENYA**

**N. NYAMARI <sup>1</sup>, D. OTIENO <sup>2</sup>, C. BOGNER <sup>1</sup>**

<sup>1</sup> University of Cologne, Institute of Geography, Cologne, GERMANY

<sup>2</sup> Jaramogi Oginga Odinga University of Science and Technology, Department of Biological Sciences, Bondo, KENYA

Continuous demand for the mobility of people and goods has accelerated infrastructural developments such as roads and railway lines. Road construction not only leads to large scale spatial landscape fragmentation, but also to local changes in soil properties. Compared to countries in the Global North, road construction in the Sub-Saharan Africa is done differently. Moreover, the local effects of road construction on soil properties are seldomly studied. In Kenya, a number of new roads have been constructed in the past decade to open up areas considered landlocked and prone to insecurity issues such as cattle rustling. Baringo County is one such area that has experienced expansion in road network. Therefore, this study sought to understand the impacts of roads on soil properties in Marigat, Baringo County. We established sampling points along transects at 0m, 250m and 500m intervals from the road edges. Soil samples were obtained to a depth of 50 cm to investigate soil properties such as bulk density, saturated hydraulic conductivity, soil moisture, grain size and C/N ratio. We also conducted penetration resistance measurements along transects at 0m, 20m and 35m intervals from the road edges for paved and unpaved roads. Our preliminary results indicate that paved roads caused higher soil compactions than unpaved roads. This study contributes to understand road impacts on soil to avoid, mitigate and compensate the impact in rural Kenya.

### SOIL AND WATER CONSERVATION IN A SMALL AGRICULTURAL CATCHMENT

J. KONECNA, M. POCHOP, P. KARASEK, J. PODHRAZSKA, E. NOVAKOVA

Research Institute for Soil and Water Conservation, PRAHA, CZECH REPUBLIC

Intensive farming in the Czech Republic brings fertilizers and also a manifold spectrum of plant protection substances into the arable land. Research on nitrogen, phosphorus and pesticides contents and dynamics in soil, sediment and surface water has been proceeding in experimental catchment Nemcice stream since 2019. It represents typical highland conditions in the CR, with sloping relief and intensive farming on large blocks.

Results obtained from monitoring showed a need to pay close attention to all potential contaminants in the environment, considering the transport processes in agricultural catchments and potential mutual influences on various environment components.

Limiting the entry of potentially risky substances (nutrients and pesticides) from agricultural land into the aquatic ecosystem is theoretically possible by reducing application doses or slowing down transport processes. The second option is the principle of the presented comprehensive soil and water conservation measures. The effect of complex measures consists in mitigating the effects of surface soil washing by water erosion, slowing down leaching of substances through the soil profile, improving the quality of subsurface water. The measures (e.g. strip cropping, grass belts, hedges, ditches, reservoirs, ...) are multifunctional in nature, which means that in addition to limiting soil degradation and contamination of surface water bodies, they contribute to increasing water retention in the agricultural landscape, mitigating the impacts of hydrological extremes (torrential rainfall and drought) and have the potential of a positive effect on the ecological stability of the agricultural landscape. They can be implemented by farmers or in process of land consolidation.

The study was created with the support within projects QK1910282, QK21010328, SS06010290, SS06020006 and RO0223.

### USE OF NATURAL-BASED REMEDIATION STRATEGY TO SUPPORT REMOVAL OF HEAVY METALS FROM SOIL

A. MEDYNSKA-JURASZEK, W. FIALKIEWICZ, K. LEJCUS, A. KANCELISTA, Z. LAZAR, A. TAMMA, J. MISIEWICZ, D. MARCZAK

Wroclaw University of Environmental and Life Sciences, Wroclaw, POLAND

Various methods have been explored to eliminate heavy metal pollutants from the soil environment. However many challenges has been indicated mainly to the low efficiency of the process, high expenses, long duration to achieve soil standards and and secondary environmental effects resulting from soil degradation caused by significant interference with the soil biota. As soil health became recently an important issue it is necessary to apply new, natural-based solution for soil remediation and restoration. The EU-funded SYMBIOREM project (Symbiotic, circular bioremediation systems and biotechnology solutions for improved environmental, economic and social sustainability in pollution control) aims to use the bioremediation capabilities of microorganisms, microbiomes, proteins, plants and animals to remove pollution from the environment. One of the main assumptions of nature-based remediation is the use of soil organisms as bioremediators, but also renewing the microbiome of chemically degraded soils building biological balance and supporting plant growth. This goal can achieved by many actions and in our project we are focusing on three main strategies: 1) soil augmentation with probiotic, 2) the use of prebiotics in the form of low molecular weight organic acids (LMOA) 3) modification of soil properties and supporting plant and microorganisms growth by application of biodegradable geocomposites. Findings of the preliminary greenhouse experiment with high biomass plant *Miscantus sinensis* and co-application of active microbes with prebiotics containing citric acids seems to be the best variant, supporting plant growth and accumulation of heavy metals in aboveground biomass.

### EFFECTS OF SUB-SOIL PLASTIC FILM MULCH ON SOIL WATER AND SALT CONTENT AND WATER UTILIZATION BY WINTER WHEAT UNDER DIFFERENT SOIL SALINITIES

B. DONG, M. ZHANG, Y. QIAO

The center for Agricultural Resources Research, Institute of Genetics and Developmental Biology, CAS, Shi

Drought and salinity strongly restrict wheat production in saline soils in North China. The sub-soil plastic film mulching was developed from traditional mulching cultivation. However, the regulation of soil water-salt movement and the mechanism of wheat yield improvement under sub-soil plastic film mulch are rare in reports. A field experiment was conducted during the winter wheat growing seasons in 2017–2023 with four replicates in the Nanpi Eco-Agricultural Experimental Station of Chinese Academy of Sciences (elevation, 11 m). The experiment included 6 treatments combining two levels of planting patterns and three levels of soil salinity. The planting pattern treatments included no-mulch (M0) and sub-soil plastic film mulch (M1). The soil salinity levels were 1‰ (S1), 2‰ (S2), and 3‰ (S3). Main results are as follows:

1. Sub-soil plastic film mulch could reduce the soil evaporation and increase soil moisture in topsoil. Sub-soil plastic film mulch had the double effects on wheat field soil temperature with the increasing in early stage and decreasing in late stage of wheat plant. Sub-soil plastic film mulch inhibited the accumulation of topsoil salinity. The Na<sup>+</sup> content in stem and leaf of wheat plants was reduced under sub-soil plastic film mulch, at the same time the K<sup>+</sup> content was increased, and Na<sup>+</sup>/K<sup>+</sup> ration was decreased.
2. Sub-soil plastic film mulch promoted the establishment of wheat population, grain yield and water use efficiency of wheat. It increased seed germination rate, improved effective tiller of wintering and recovery stage, and increased dry matter accumulation and root development. It improved winter wheat yield by increasing spike number and grain number per spike. It decreased E/ET ratio and converted more soil water into plant transpiration, and water use efficiency was improved.

### SOIL EROSION AND FERTILITY INTERLINKAGES IN UGANDA'S LANDSCAPE: EFFECTS OF LOCAL CLIMATE-SMART SOLUTIONS ON SOIL PROPERTIES.

J. NDEMERE <sup>1</sup>, B. KONE <sup>1</sup>, B. WILSON <sup>2</sup>, M. PARADELO <sup>3</sup>

<sup>1</sup> Faculty of Soil Sciences, Environment and Sustainable Agriculture, University Félix Houphouët Boigny, Cocody, IVORY COAST

<sup>2</sup> Faculty of Agriculture and Environmental Sciences, Kabale University, Kabale, UGANDA

<sup>3</sup> Natural Resources Institute - University of Greenwich, Chatham Maritime, Kent, UNITED KINGDOM

Soil degradation, particularly the depletion of soil nutrients due to erosion, is exerting significant pressure on farming systems worldwide. The Sub-Saharan countries, including Uganda's highlands, experience soil degradation primarily due to soil erosion. This causes a decline in farmland productivity and threatens smallholder farmers' livelihoods. In Uganda's highlands, farmers are introducing climate-smart solutions (CSS) to reduce erosion and improve soil fertility.

We evaluate the effect of climate-smart solutions (CSS) implemented in two of Uganda's districts on soil properties. The study area, Kabale and Rubanda districts are situated in the Kigezi subregion, southwestern Uganda. Plots were selected based on the use of CSSs against soil erosion and to maintain soil fertility and non-CSS plots susceptible to soil erosion. The CSS practised in the area were terraces, check dams, Fanya chini, Napier grasses, crop residues, selected tree species, and organic manure application for more than 15 years. The plots were selected from six different mountain hills at three positions (top, middle and bottom). At each location CSS and non-CSS plots were sampled. Soil samples were collected from 10 m × 10 m quadrat plots at a depth of 0–14 cm and 15–30 cm.

Overall, organic matter increased in the CSS plots compared with the non-CSS plots ( $p = 5.1e-9$ ), with higher accumulation on the bottom plots and in the upper 15 cm. Bulk density decreased in the CSS plots. CSS did not improve the saturated hydraulic conductivity measured in the lab, which was controlled by texture. Climate smart solutions enhanced chemical fertility by increasing CEC, and available P. The pH also increased to levels that enhance nutrient availability, but the position has also a significant influence. Climate smart solutions can help smallholder farmers towards soil health and increase the resilience a fertility of their farms.

### EFFICIENCY OF COSOLVENT FLUSHING FOR THE REMEDIATION OF SOIL AND GROUNDWATER CONTAMINATED WITH NAPLS

#### Authors

K. YAKSI, [N.K. COPTY](#)

Institute of Environmental Sciences, Bogazici University, Istanbul, TURKEY

Contamination of the soil and groundwater with organic contaminants in the form of non-aqueous phase liquids (NAPLs) is a widespread and challenging environmental threat. Because of their high interfacial tension, low solubility and low degradation potential, NAPL releases into the subsurface persist for many decades, continuously contaminating large volumes of the groundwater and threatening the security of this vital water resource. This in turn can have severe adverse impacts on food security and human health. Cosolvent flushing has evolved as an effective and cost efficient remediation technology for the remediation of groundwater resources contaminated with non-aqueous phase liquids (NAPLs). For the successful application of this remediation technology, there is a need to accurately define the interphase mass transfer, a key processing controlling the fate of NAPLs in the groundwater. This study examines the effect of cosolvents on the interphase mass transfer of NAPLs in porous media. Two dimensional dissolution experiments are conducted to generate interphase mass transfer expressions. The experimental data are then modeled using numerically and used to develop Sherwood correlations that relate the interphase mass transfer to flushing velocity, soil properties and flushing solution composition. It is observed that the flushing solution properties such as viscosity and density directly influence the interphase mass transfer and the efficiency of the DNAPL remediation process.

<sup>3</sup> INTERNATIONAL RICE RESEARCH INSTITUTE, DELHI, INDIA

<sup>4</sup> INTERNATIONAL RICE RESEARCH INSTITUTE, VARANASI, INDIA

This study explores the influence of different levels of arsenic and biochar on the arsenic status in soil following the harvest of two rice crops. The investigation aims to understand the interactions and effects of these factors on soil arsenic content. The results indicate significant variations in arsenic levels based on different treatments. Specifically, treatment T3, characterized by a high arsenic concentration, exhibits substantially higher arsenic content compared to other treatments involving biochar application. Conversely, treatment T7, which involves the application of iron-modified biochar with a high dose, demonstrates the lowest arsenic content. The study provides valuable insights into the complex dynamics between arsenic, biochar, and soil, contributing to our understanding of potential strategies for managing arsenic levels in agricultural soils.

### COVER CROP AS A NEW ALTERNATIVE IN THE GREENHOUSE - DIFFERENT ORGANIC MATTER MANAGEMENT OPTIONS IN CULTIVATION

E. PAPDI, F. KOVÁCS, Z. KOTROCZÓ, K. JUHOS

Hungarian University of Agriculture and Life Sciences, Department of Agro-Environmental Studies, Budapest, HUNGARY

Intensively chemicalized vegetable production results in physical, chemical and biological degradation of greenhouse soils. Soil degradation is a serious problem in today's environment, and we need to find solutions that improve crop loss, not increase costs for farmers. According to our hypothesis, nutrient utilization can be improved with appropriate organic matter management, and the harmful effects of monoculture can be reduced in the long term. The experiment was carried out in a greenhouse, on sand soil with weak humus. Five different treatments were used: Control (0.04kg/m<sup>2</sup> N-fertilizer; MT), Cattle manure (6kg/m<sup>2</sup>; IT), Double cattle manure (12.8kg/m<sup>2</sup>; DT), Winter cover crop (0.006kg/m<sup>2</sup>; TN), Winter cover crop + Trichoderma (6g/m<sup>2</sup> +0.002 L/m<sup>2</sup>; TT). Each treatment at the appearance of the first berry crops 10g/m<sup>2</sup> N active ingredient. In the experiment, we used two years of soil sample data, from which we examined the POXC content of the soil, FDA activity, PHOS enzyme activity and soil nitrate content, as well as the yield. We found that mainly the cover plant treatments helped to increase the biological activity. The rich rhizosphere contributed to soil improvement by increasing organic matter and creating habitat. By the second year, FDA activity doubled for each treatment. Similar to the FDA activity, the POXC values also doubled. At the end of the growing season, soil nitrate content was significantly higher in the TN and TT treatments compared to the other treatments. Based on this, we conclude that the use of winter cover crops reduced nitrate leaching, thereby leaving more nitrogen in the soil. The nitrate content and phosphatase activity of the soil can also be related to the higher yield observed in the TT treatment.

### INTEGRATIVE STRATEGIES FOR RESTORING SEVERELY DEGRADED CERRADO SOIL THROUGH SOIL AMENDMENTS

T. SOTO BONI<sup>1</sup>, K. .L. MALTONI<sup>2</sup>, E. .I. PUJOL PEREIRA<sup>3</sup>

<sup>1</sup> São Paulo State University, Ilha Solteira, BRAZIL

<sup>2</sup> São Paulo State University, Ilha Solteira, BRAZIL

<sup>3</sup> The University of Texas Rio Grande Valley, Edinburg, USA

In order to reestablish a thriving ecosystem in a degraded Cerrado biome, we are restoring a degraded site located in Southeast of Mato Grosso do Sul, Brazil. The site had suffered severe soil degradation during the construction of a Hydroelectric Power Plant (HPP) in the 1960s, which resulted in the removal of the soil's surface layer (up to 12 meters) and exposure of the subsurface layer. This has led to the complete absence of vegetation and the accumulation of soil erosion, rendering the area unstable and unsuitable for supporting any ecosystem. Our research is focused on identifying a combination of soil amendments that can effectively improve the composition of Cerrado's soil (Oxisol; Ferralsol) for restoration purposes. To achieve this goal, the area received different levels of biomass introduction and 12 treatments were implemented, ranging from no manipulation to the addition of various organic compounds, sheep residue, brushwood transposition, and native seed species. Soil samples were collected from a depth of 0.0 to 0.1 m, 24 months after the treatments were introduced. To assess microbial activity, we measured soil enzyme activity, including beta-glucosidase, phosphatase, and total enzyme activity (FDA), as well as other soil chemical attributes that can be improved by the amendments used. The vegetation cover of the experimental area was assessed using aerial images collected with a drone, and the percentage of the area of each plot was estimated. Temperature measurements were taken, with a stem thermometer, at dawn and in the afternoon, at a depth of 0.05 m, and soil moisture was also assessed by gravimetry (0 to 0.05 m). By analyzing these methods, we aim to determine which treatment will respond most favorably to the different recovery techniques and residues added. Our ultimate goal is to apply these findings to other degraded areas and restore their once-thriving ecosystems by replicating these successful methods.

## 4. Soil health in achieving the Sustainable Development Goals 4.12 133530 - Soil degradation control, remediation and reclamation

**METHOD OF THE BLACK SOILS ECOLOGICAL STATE IMPROVING UNDER MILITARY AND TECHNOGENIC INFLUENCES ON AGROCOENOSES IN THE KURAKHIV TPP AREA OF DONETSK REGION**

V. SAMOKHVALOVA<sup>1</sup>, O. BONDAREVA<sup>2</sup>, O. VINYUKOV<sup>2</sup>

<sup>1</sup> NATIONAL SCIENTIFIC CENTER «INSTITUTE FOR SOIL SCIENCE AND AGROCHEMISTRY RESEARCH NAMED AFTER O.N. SOKOLOVSKY» -SOIL CON, KHARKIV, UKRAINE

<sup>2</sup> DONETSK STATE AGRICULTURAL RESEARCH STATION, POKROVSK, UKRAINE

The new method for soil degradation control and remediation of chemically contaminated black soils under military-technogenic influences has been tested. Method includes the use of elaborated effective composition of the new Smaragd chelate-humate preparation (Smaragd HGP, utility model patent 135145 UA, 2019). Method tested on soils near zones of Kurakhiv TPP industrial activities area and zones of military disturbed soils of land plots with pits from 1 m to 4 m and identification of weapons types in particular shelling from MLRS and missile strikes in conjunction with its individual characteristics and preliminary determination of the soil-plant system ecological state. Test plants - *Hordeum vulgare*. The priority of Cd, Pb, Zn, Cu mobile forms was established. Determined that translocation intensity of toxic metals forms a series - Zn>Cu>Pb>Cd. Under military influence, the destruction of the soil surface with the formation of craters was revealed; clogging with metal fragments, pollution with chemical substances in the places of explosions of shells and rockets. Exceeding the background levels of toxic metals Hg, Cd, Pb, Cu, Ni in the soil was established. An excess of the background content of Hg, Cd, Pb up to 1.5 times was recorded in the places of combat operations and to 7–17 times - in the places where shells hit and craters were formed. It was established that the largest number of soil craters in the studied areas were formed during shelling using the Grad installation, field and self-propelled howitzers; caliber 120 mm and mortars with 82-mm fragmentation shells and high-explosive fragmentation mines, caliber 82 mm. The plants observations established the positive influence of Smaragd HGP on the crop productivity, crop structure. The benefits of using the elaborated method are established. Recommended method implementing for farms specializing in the production of grain crops in territories with complex negative effects of the military factor and chemical pollution to restore the black soils health, reduce the intensity of chemical degradation processes.

### DEGRADATION OF CHLORPYRIFOS IN A ANDISOL TREATED WITH VERMICOMPOSTS CO-PRODUCED WITH BIOCARBON

C. MUÑOZ, J. HENRÍQUEZ, B. RAMÍREZ

Universidad de Concepción, Chillán, CHILE

The long-standing practice of pesticide use in agriculture is under scrutiny due to increasing concerns over environmental and health risks. The use of chlorpyrifos (CP), a moderately toxic pesticide with extensive effects that lasts in the environment for 10 to 120 days, it continues to be utilized in some countries. One of the toxic byproducts of chlorpyrifos decomposition is the broad-spectrum antimicrobial metabolite, 3,5,6-trichloro-2-pyridinol (TCP), which remains in the soil for a prolonged period. Bioremediation methods could include the use of microorganisms and Earthworms; and the biochar has been proposed as a potential carrier for microbes. The aim was to assess the effectiveness of using vermicompost mixed with biochar for the biological degradation of CP in an Andisol. A randomized method was used, starting with vermicompost made with 1% biochar and incubated for three months. Three treatments were set up in triplicate: a control with pesticides (T0), vermicompost with pesticides (T1), and vermicompost mixed with pine pruning biochar with CP (1.25% v/v; T2). Measurements of CE activity and pesticide residues were taken at 15, 30, and 45 days of incubation, conducted at 25 °C in the dark at field capacity. Results shown a notable increase after the 30th day in soils treated with CP. Remarkable differences in CP degradation in T2 compared to T0 between day 15 and 30. As the CP concentration decreased over the 45-day period in all treatments, the concentration of TCP increased. The CP residues in the reference soil could have caused microbial adaptation leading a decrease in CP application and suppression of the CE enzyme due to pesticide toxicity. However, microorganisms demonstrated their ability to decompose CP into a source of carbon and energy, leading to increased CE activity after 30 days. The combination of vermicompost and biochar may have aided in the microbial degradation of CP, although the possible immobilization of CP on the biochar surface needs further examination. Thanks to Project Fondecyt 1210503.

### EFFECT OF CIRCULAR BUFFER STRIPS OF NATIVE PERENNIAL GRASSES ON WIND EROSION IN THE SOUTHERN GREAT PLAINS OF UNITED STATES

S. ANGADI<sup>1</sup>, P. SINGH<sup>2</sup>, M. NIELSON<sup>1</sup>, G. YADAHALLI<sup>1</sup>, R. GHIMIRE<sup>1</sup>, J. IDOWU<sup>1</sup>

<sup>1</sup> New Mexico State University, Las Cruces, USA

<sup>2</sup> University of California, Agriculture and Natural Resources, Salinas, USA

Wind erosion is a serious challenge faced by agriculture in the Southern Great Plains, severity of which is increasing with declining Ogallala Aquifer, increasing climate extremes, poor soil health and lack of ground cover. The wind is strong early in the spring, when soil cover is less and seedlings are small, causing loss of valuable topsoil and damage to seedlings by sand abrasion. A novel concept of reintroducing tall growing native perennial grasses into center pivot irrigated agriculture developed by us was tested for moderating wind erosion. Southwest facing (predominant wind direction) wedges of two adjoining pivots, one with circular buffer strips (CBS) and the other conventional control pivot, were used for the study. Three replicates of BSNE dust samplers were installed at three different distances from edges at 5 (D1), 30 (D2) and 55 (D3) ft from southwest wedge were installed at 0.15 and 0.60m (only in 2022) were installed in both wedges. Dust samplers were also installed in the middle of outer two grass strips. Periodically or after each windstorm, dust was collected and weighed. At the same time, wind data was collected from 2D sonic anemometers. Grass buffers reduced wind erosion significantly in 2021 and amount of soil collected reduced as we moved inside from the wedge. Comparing similar distances with and without CBS, soil erosion reduced by 60 to 95% in 2021. However, in 2022 the benefit of grass buffers was not seen due to drought year and a large no till plot to the southwest of CBS pivot. Adding second BSNE at 0.60m indicated that more soil was collect in that. Overall, the data suggests that most of the soil was blown from outside the pivots and first buffer strip was efficient in collecting that soil.

### SPATIAL VARIABILITY OF SOIL COMPACTION IN INTENSIVE VINEYARDS AND ORCHARDS

Z. RIJAVEC, B. VRSCAJ

Agriculture Institute of Slovenia, Department of Agricultural Ecology and Natural Resources (DAENR), Ljubljana, SLOVENIA

Excessive soil compaction is a widespread soil degradation mainly caused by heavy machinery, especially when moved on the same tracks. It is generally assumed that all vineyards and orchards are highly compacted due to the intensive use of machinery. The green belt (area between the wheel tracks) and the cultivation belt (area between the plants in a row) occupy a large part of the plantations. Aim of the study was to collect initial information on soil compaction in vineyards and orchards in different parts of the rows and different soil groups in order to better plan systematic monitoring of soil compaction. 10 vineyards and 10 orchards were selected that met several. In each orchard or vineyard, compaction was measured at 5 representative sites, each in three areas in a row. Compaction was measured to a depth of 40 cm or less in shallow soils using a computerised hydraulic penetrometer. The device moves two penetrometer cones vertically while measuring and recording a penetration force of up to 500 N. Results showed that the soils of vineyards and orchards are dominated by non-compacted soils. Soil compaction in the green and cultivation belt (1537 kPa, 1546 kPa) is lower than in the belt between the wheel tracks (1761 kPa). In the green and cultivated belt the compaction increases with soil depth. On the wheel tracks compaction is highest on the surface between 0 and 10 cm and it decreases at a depth of between 10 and 25 cm, deeper down, compaction increases again. Results confirm the diversity of soil compaction within the permanent planting areas and in relation to three different tillage belts, soil type and selected soil parameters. The information gathered will help to define procedures for monitoring soil compaction in permanent plantations where plants are grown in rows, as well as measurement patterns for soil compaction on wheel tracks, in the green belt and in the cultivation belt.

### THE INTERNATIONAL NETWORK ON SOIL POLLUTION: TOWARDS THE GLOBAL GOAL OF ZERO POLLUTION

S. USTINOV

Food and Agriculture OrgaNIZATION OF THE UNITED NATIONS, Rome, ITALY

Soil pollution is one of the main threats affecting soil health worldwide. However, soil pollution is unique to other threats such as erosion or salinization: it is difficult to perceive with the naked eye, and its effects are only visible when the level of pollution causes acute effects on the environment and human health. The Food and Agricultural Organization's Global Soil Partnership (GSP) seized the momentum and advanced the coordination of global actions on soil pollution to address key knowledge gaps and improve technical capacities to detect, quantify, monitor and mitigate soil pollution. The publication of the Global Assessment of Soil Pollution by FAO and the United Nations Environment Programme (UNEP) in 2021 laid the foundation for developing concrete actions to achieve a zero pollution future and set a clear agenda for action. During recent global efforts to combat soil pollution, one of the proposed actions was to establish the International Network on Soil Pollution (INSOP) in 2022. This network brings together all stakeholders in an effective, coordinated, and inclusive manner to advance towards a world with Zero Pollution. The creation of this network was an urgent response to the need for a global action agenda on soil pollution.

As of today, the INSOP consists of more than 1,200 members represented from 130 countries, driving the network to achieve its 2023-2025 agenda. The INSOP is pleased to present progress on developing global soil pollutant threshold values, a summary of available legal instruments for soil pollution, a remediation action checklist, as well as the new FAO Technical Guidelines on Soil Pollution Assessment, Mapping, Monitoring and Risk Communication. Furthermore, INSOP is increasing its engagement with farming communities worldwide by training them on soil pollution prevention, adaptation, and mitigation as part of the Global Soil Doctors Programme.

<sup>3</sup> University of Canterbury, Christchurch, NEW ZEALAND

Extensive use of fungicide copper (Cu) has a more recent history in New Zealand than in many other parts of the world where long-lasting Cu accumulation in soil has become a significant environmental issue. Currently in NZ, inorganic formulations of Cu are routinely applied to a range of fruit crops including organic orchards. This study investigates whether accumulation and persistence of Cu in soils adversely affects soil functionality in selected cherry, apple, kiwifruit orchards, vineyards and hop gardens. We report experimental findings from field, mesocosm and glasshouse studies on soil respiration and a range of soil biotic variables. Across the orchards, soil Cu concentrations frequently and substantially exceeded most published threshold limit concentrations for contamination that are 100 mg kg<sup>-1</sup> (total Cu). Soil and vegetation management within and beneath rows of trees largely explained horizontal and vertical dispersion patterns of the metal in soil. Soil organic matter (SOM) played the largest role in Cu retention, as a stronger determinant than Cu of soil respiration, microbial biomass carbon and nitrogen, and earthworm toxicity and behaviour. In most cases, critical concentration where impacts could be detected approached 250 mg Cu kg<sup>-1</sup>. Significant responses to Cu were detected in plant root growth, microbial activity and earthworm, but deleterious impacts were largely mitigated by SOM content in combination with avoidance of low soil pH. It is well known that residual Cu does not significantly dissipate in the environment and the metal is likely to continue to accumulate in the orchard soils. We conclude that mitigation or amelioration of risk through management of these variables is unrealistic: sustainable soil health management in New Zealand's orchards is not viable with longer-term continued usage of inorganic Cu-fungicides.

Biochar, which including pyrochar (PBC) and hydrochar (HBC), has been tested as a soil enhancer to improve saline soils. However, the effects of PBC and HBC application on ammonia (NH<sub>3</sub>) volatilization and dissolved organic matter (DOM) in saline paddy soils are poorly understood. In this research, marsh moss-derived PBC and HBC biochar types were applied to paddy saline soils at 0.5% (w/w) and 1.5% (w/w) rates to assess their impact on soil NH<sub>3</sub> volatilization and DOM using a soil column experiment. The results revealed that soil NH<sub>3</sub> volatilization significantly increased by 56.1% in the treatment with 1.5% (w/w) HBC compared to the control without PBC or HBC. Conversely, PBC and the lower application rate of HBC led to decreases in NH<sub>3</sub> volatilization ranging from 2.4% to 12.1%. Floodwater EC is a dominant factor in NH<sub>3</sub> emission. Furthermore, the fluorescence intensities of the four fractions (all humic substances) were found to be significantly higher in the 1.5% (w/w) HBC treatment applied compared to the other treatments, as indicated by parallel factor analysis modeling. This study highlights the potential for soil NH<sub>3</sub> losses and DOM leaching in saline paddy soils due to the high application rate of HBC. These findings offer valuable insights into the effects of PBC and HBC on rice paddy saline soil ecosystems.

Soil salinity limited agricultural development and affected ecological environment development in the Hetao Irrigation Region, Inner Mongolia, China. In this study, three amendments include flue gas desulfurization gypsum (S), humic acid (H), and biochar (C) were used for soil amelioration with sunflower planting during two years experiment. The humic acid applied before each seedling season, the rest two materials applied only once. Results showed that the three amendments all increased soil water holding capacity at depth of 0-20 cm, decreased soil salinity during sunflower growth, increased macro aggregate proportion. Humic acid treatment had the best effect on reducing soil salt content after seedling stage. Biochar decreased soil bulk density (1.34 g cm<sup>-3</sup>) and mostly increased the sunflower seed yield up to 3133-3964 kg hm<sup>-2</sup>. Humic acid addition significantly increased aggregate (>0.25mm) content up to 27.88% after the experiment, but got a lower seed yield (2607-3686 kg hm<sup>-2</sup>). The temperature in 2019 was entirely lower than the 2018, which thought to be the main reason caused the yield reduction. And the three amendments could all maintain and increased the yield than conventional cultivation. The effects of the three materials on larger scale lands and longer time need further research. This study supplied scientific guidance for developing saline agriculture in the Hetao Irrigation areas.

<sup>4</sup> Institute of Coast Agriculture, Hebei Academy of Agriculture and Forestry Sciences, Caofeidian, CHINA

Salt-affected soils frequently experience leaching and desalination issues, which severely restrict plant growth and water uptake. Hence, in this experiment, four treatments including CG (no amendments addition); OF (organic fertilizer addition); OH (organic fertilizer and Hekang amendment addition); and OB (organic fertilizer and fulvic acid addition) were designed to examine the effect of organic amendment on soil chemical properties, water and salt transport, and soil desalination laws of coastal saline soil. The results showed that the addition of organic amendment significantly reduced soil pH (8.47–8.52) and salt content (2.06–2.34 g/kg), while increasing soil organic matter content, available phosphorus, and available potassium. OH treatment has a higher available phosphorus content than other treatments. OH and OB treatments elevated the soil desalination ratio (32.95% and 32.12%, respectively) by raising the leaching volume and leaching rate. Organic amendments significantly promoted Sodium ion (4.5–32%) and Sulfate ion (12–27%) leaching compared to CG. Organic treatments, particularly OB treatment, not only increased the content of soil organic matter and available nutrients but also promoted salt ion leaching, improved soil permeability and increased soil desalination and water leaching rates. Our results may provide a theoretical basis for revealing the desalination law of coastal saline soil.

**Keywords:** coastal saline soil, organic fertilizer, soil nutrient content, water and salt migration, desalination rate

<sup>2</sup> ENI REWIND SPA, MILANO, ITALY

Mycoremediation is a bioremediation technique, relying on the use of fungal inocula to reclaim contaminated soils. Total Petroleum Hydrocarbons (TPH) are widespread organic pollutants, and their presence is a primary cause of soil contamination in Europe. In this frame, the LIFE MySOIL project (<https://lifemysoil.eu>) aims to demonstrate the viability of the mycoremediation technology to remove petroleum-derived organic pollutants from aged industrial contaminated soils. Moreover, the project focuses on the appraisal of the environmental and socio-economic impact of the application of mycoremediation as compared to other technologies, as well as its ability to promote the circular economy principles through the recovery of soil and the use of agro-industrial products, like Spent-Mushrooms-Substrate (SMS), as a viable source of fungal inoculum.

The feasibility assessment of the mycoremediation process involved a sequential approach which, starting from biotreatability tests, passed through the implementation of mesocosms (1 m<sup>3</sup> working capacity) up to large-scale biopiles (50 m<sup>3</sup> working capacity). The biotreatability tests enabled the selection of two *P. ostreatus* strains (P24 and P80), which were then used in mesocosm experiments where they were compared with SMS from the same species for contaminant degradation performance, inoculum persistence, and impact on resident microbial communities. This contribution will focus on the results obtained in the biotreatability and mesocosm test conducted on a TPH-contaminated clay-soil collected from an Enilive Station, a mobility services hub for drivers located in Borgo Faiti (LT).

Reducing the bioavailability of both cadmium (Cd) and arsenic (As) in paddy fields is a worldwide challenge. We investigated whether ridge cultivation combined with biochar or calcium-magnesium-phosphorus (CMP) fertilizer effectively reduces the accumulation of Cd and As in rice grains. Field trial showed that applying biochar or CMP on the ridges was similar to the continuous flooding, which maintained grain Cd at a low level, but grain As was reduced by 55.6%, 46.8% (Ilyou28) and 61.9%, 59.3% (Ruiyou 399). Compared with ridging alone, the application of biochar or CMP decreased grain Cd by 38.7%, 37.8% (Ilyou28) and 67.58%, 60.98% (Ruiyou399), and reduced grain As by 38.9%, 26.9% (Ilyou28) and 39.7%, 35.5% (Ruiyou 399). Microcosm experiment showed that applying biochar and CMP on the ridges decreased As in soil solution by 75.6% and 82.5%, respectively, and kept Cd at a comparably low level at 0.13–0.15 ug/L. Aggregated boosted tree (ABT) analysis revealed that ridge cultivation combined with soil amendments altered soil pH, redox state (Eh) and enhanced the interaction of Ca, Fe, Mn with As and Cd, which promoted the concerted reduction of As and Cd bioavailability. Application of biochar on the ridges enhanced the effects of Ca and Mn to maintain a low level of Cd, and enhanced the effects of pH to reduce As in soil solution. Similar to ridging alone, applying CMP on the ridges enhanced the effects of Mn to reduce As in soil solution, and enhanced the effects of pH and Mn to maintain Cd at a low level. Ridging also promoted the association of As with poorly/well-crystalline Fe/Al and the association of Cd on Mn-oxides. This study provides an effective and environmentally friendly method to decrease Cd and As bioavailability in paddy fields and mitigate Cd and As accumulation in rice grain.

### BIOREMEDIATION POTENTIAL OF NATIVE FUNGAL STRAINS ISOLATED FROM SOILS IN THE PUCHUNCAVÍ-VENTANAS AREA THAT EXHIBIT TOLERANCE TO HEAVY METALS

X. FADIC <sup>1</sup>, F. REYES <sup>2</sup>, E. LOBAINA <sup>2</sup>, R. CERNA <sup>2</sup>, A. VERGARA <sup>2</sup>, F. CERECEDA-BALIC <sup>3</sup>, M. CARVAJAL <sup>2,3</sup>

<sup>1</sup> Centre for Environmental Technologies (CETAM), Universidad Técnica Federico Santa María, VALPARAISO, CHILE

<sup>2</sup> Centro de Biotecnología (CBDAL), (2) Universidad Técnica Federico Santa María, VALPARAISO, CHILE

<sup>3</sup> Department of Chemistry, Universidad Técnica Federico Santa María, VALPARAISO, CHILE

Soil contamination by heavy metals (HM) is a problem that affects ecosystems and productive sectors, causing a decrease in biodiversity and agricultural productivity. In Puchuncaví-Ventanas (a coastal area in central Chile), an industrial complex has existed since 1960. Today, it consists of more than 20 companies, mainly a copper smelter and refinery, and coal-fired thermal power plants. Several studies have shown the presence of high concentrations of heavy metals in the surrounding soils. A promising approach to remove heavy metals from contaminated soils is fungal bioremediation. This work aims to characterize the heavy metal tolerance of 2 native fungal strains isolated from the study area. The strains studied were partially identified by comparative internal transcribed spacer (ITS) sequence analysis (*Trichoderma* TM1 and *Mortierella* LA7). Tolerance to As, Pb, Cu, Cr, Co was evaluated in in-vitro assays using Potato Dextrose Agar (PDA) culture medium and in control soils, both supplemented with increasing concentrations of each HM. Tolerance indices (TI) were determined, showing high TI for TM1 for Pb (100% at 300 and 450 ppm) and 100%, 51% and 35% for 100, 200 and 300 ppm Cu, respectively. LA7 showed high lead tolerance with TI of 63%, 58% and 71% at 300, 450 and 800 ppm and 69%, 56% and 45% at 100, 200 and 300 ppm (Cu), respectively. Morphological differences between metal treatments and controls were visualized by scanning electron microscopy. Growth in contaminated soil (under ex situ conditions) indicated that *Trichoderma* sp. remained viable for at least several months after application to soil, suggesting possible removal mechanisms associated with its tolerance and where a decrease in the concentration of available heavy metals (under investigation) is expected. ICP-MS and XRF analytical techniques are used for this purpose. The strains studied are attractive candidates for bioremediation strategies in heavy metal contaminated soils.

The launch of the Soil Mission campaign in the European Union initiated a new approach to problems related to soil degradation. In addition, the need to increase awareness of soils at various levels of education was understood. Our project LOESS - Literacy boost through an Operational Educational Ecosystem of Societal actors on Soil health focuses on increasing soil literacy, via developing educational offers and continuous training programmes as well as skills development activities addressing multiple actors, stakeholders and target groups connected to soil education. For this purpose, it is necessary to recognize the current level of education in the field of soil science and point out the gaps in education. The analysis of education programs at the primary and secondary level in Poland showed, that the choice of teaching methods depends on the teacher, which makes it difficult to control the form of teaching. In addition, the way in which the activities are implemented is often related to the financial capabilities of the school. This, in turn, leads to the dominance of the type of teaching by knowledge rather than by doing. Further analysis indicates that soil, is treated as an element of food production, while the programs do not mention issues related to soil as a non-renewable resource, or its role in the context of climate change such as participation in carbon sequestration. Nor was there any reference to the need for soil conservation in the context of healthy soil. Furthermore, the importance of soil in achieving the Sustainable Development Goals has not been adequately addressed. Preliminary research indicates an urgent need for changes to the core curriculum in schools at both levels of education.

### FORMAL AND INFORMAL EDUCATION IN THE FIELD OF SOILS IN POLAND – GOOD PRACTICES

M. SZCZEPANSKA<sup>1</sup>, E. KACPRZAK<sup>1</sup>, B. MACKIEWICZ<sup>1</sup>, K. LEWINSKA<sup>2</sup>, J. MORAWSKA<sup>1</sup>, C. KAZMIEROWSKI<sup>2</sup>

<sup>2</sup> Adam Mickiewicz University in Poznan, Faculty of Geographical and Geological Sciences, Poznan, POLAND

The method of managing the soil environment is key to ensuring, among others: food security, biodiversity. Rational soil management should take into account all soil functions: production, habitat and retention. This approach requires an appropriate level of soil knowledge in society. One of the goals of LOESS project is to increase knowledge about soil and develop skills in its appropriate use. Polish society acquires knowledge about soil in primary and secondary schools and as part of studies in fields closely related to soil, e.g. horticulture, agriculture, forestry, geology, environmental protection. Education is for free, as well as access to educational materials. Our study was based on an analysis of the core curriculum and a review of websites related to teaching about the soil. We used desk research and case study methods. It was shown that activating methods (e.g. experiments, field exercises) are underused at the primary and secondary levels of education. In vocational and college education (in fields related to soil education), educational offerings favor learning through practice, e.g. in specialized laboratories or using as tools eg. experimental gardens, demonstration farms. Thus, there are still too few innovative and attractive methods of teaching about soils available to the general public. It is therefore necessary to search for, develop and promote good educational practices that raise public awareness of soils. Our study identified several innovative examples of soil education in Poland that may also be applicable in other countries. We conducted a multi-faceted analysis of: Field Days - the largest agricultural event in Poland; Soil Museum in Krakow – museum and educational offer; Experimental heritage gardens in Poznan - permaculture design workshops; Integrated educational platform - educational materials taking into account active teaching methods.

<sup>3</sup> Aichi University, Nagoya, JAPAN

<sup>4</sup> University of Belgrade, Faculty of Forestry, Belgrade, SERBIA

Growing crops in plastic greenhouses and mulching with plastics is one of the largest sources of microplastics in the environment around the world and especially in Serbia. Plastic waste is known for its stability and recalcitrance in the environment, so it is generally assumed that standard plastic waste is not degradable. The determination of microplastics in soil is a major challenge due to the complexity of the soil matrix. The aim of the study was to show the effects of plastic particles on the chemical, physical and biological properties of arable soils. Alluvial soils from three major river basins (Danube, Morava and Sava) in Serbia, which are most affected by seasonal flooding, were selected. Soils from MP-polluted (plasticulture) and non-polluted (open field) sites, located next to each other, were sampled in 2022 from two depths 0-15 and 15-30 cm. Preliminary results showed that the physical, chemical and biological properties of the soil were significantly affected by the presence of plastics. Plastic contamination in the soil environment has an impact on organic matter cycling, global carbon dioxide production, plant production, soil properties, water quality, etc. It is time to raise awareness that the pollution of our environment with plastic waste can lead to serious disruptions of the ecosystem and its ability to fulfil its functions, such as the production of sufficient and high-quality quantities of food.

### HOW TO PROMOTE SOIL EDUCATION WITH EXISTING SCHOOL CURRICULUM IN JAPAN, EXAMPLES AND LIMIT

K. MORI<sup>1</sup>, Y. ASANO<sup>2</sup>

<sup>1</sup> Saitama Museum of Rivers, Yorii, JAPAN

<sup>2</sup> Faculty of Education, Kagoshima University, Kagoshima, JAPAN

Japanese education curriculum for primary and secondary school hardly deals with soil. We report some cases of soil concerned practice with existing education curriculum in Japanese primary school. For example, in the 6th grade's subject "Formation and change of land", only geological aspect is focused. According to the experience of giving additional lecture on this subject, we found that explanation of the dynamics of deposition of gravels by flooding, formation of alluvial plain, and subsequent use of such land and soil by human as paddy fields is effective for students to recognize the land surface is covered with soil and supporting their life. The subject could be further expanded to cover not only natural science but also social studies and comprehensive studies of the local area, since it is comparable with Andosols on plateau and its non-paddy uses. However, implementation of systematic soil education is limited under the existing curriculum. For example, room for teaching fundamental knowledge, "what SOIL is made of?" cannot be found. Establishment of an international guideline on soil education would make teachers, government officers and others aware of the importance of soil education and would be convincing and reliable reference for future revision of education curriculum.

### TEACHING SOIL SCIENCE BY COMBINING PRACTICE IN SCHOOL GARDENS AND UTILIZING DIGITAL TECHNOLOGIES TO ENHANCE CREATIVE AND INTERACTIVE LEARNING

K. TOMA, G. NAGY

University of Tokaj, Sárospatak, HUNGARY

Raising awareness about soil, our most valuable, non-renewable natural resource, should be an important part of education, already from primary school, applying well-balanced theory and practice, based on the principle of "learning by doing" and utilizing the creativity of children. School gardens are an educational resource, offering nature experiences, demonstrating ecological connections, and providing space for creative projects. The outdoor environment is seen as a complementary classroom that stimulates the different interests and abilities of children and young people. The school garden is of great importance for children to experience a sense of home, identity, and a reflection of their own culture, understand ecosystems, their services, and functions. For the schoolyard to function in this way, it is important that the pupils have a great opportunity to influence how the schoolyard is designed and used. For the teacher, this includes an important didactic task to illustrate that the soil is a living system, it is an ecosystem itself with a vast biodiversity and a central role in global biogeochemical processes. At the same time, the issues of soil degradation and pollution, the transformation of soil into 'non-soil' and the global consequences of soil mismanagement shall be emphasized in an interesting and entertaining way, completing the theoretical learning and school garden practice with interactive programmes, using digital technologies, and utilizing AI resources, enhancing herewith the understanding of natural processes and the development of system thinking. Intelligent adaptive systems and learning analytics are concepts that are increasingly common in discussions about school digitalisation. Adaptive systems can be described as a digital learning environment that automatically adapts teaching and learning resources to individual students' abilities and needs. Intelligent adaptivity is when artificial intelligence (AI) is used for this adaptation. For example, AI in education can be used to monitor students' progress, understand their current strengths and difficulties, and provide timely feedback in the form of explanations and appropriate tasks. Here we suggest a novel education model for applied ecology, where soil conservation has a central role, and the programme combines practice based learning and digital technologies with AI containing elements of gamification to increase the motivation of pupils and enhance their cognitive development.

### CO-CULTURE OF RICE AND AQUATIC ANIMALS ENHANCES SOIL ORGANIC CARBON: A META-ANALYSIS

C. MA, S.X. LI, W.B. LI, M.X. LU, S.M. YE, Z. ZHANG

Anhui Agricultural University, Hefei, CHINA

Co-culture of rice (*Oryza sativa*) and aquatic animals (CRAAs) is an efficient eco-agricultural model and has been widely implemented in many Asia countries. However, its impact on soil organic carbon (SOC) content has not been synthesized and the relative effects of different CRAAs practices on SOC have not been assessed. Our meta-analysis aims to synthesize the effect of diverse CRAAs regimes on SOC content based on results from field experiments. Our results showed that overall, CRAAs significantly increased SOC content by 11.6% ( $P < 0.05$ ). The highest relative effect on SOC content was found under the rice and amphibian coculture ( $P < 0.05$ ) practice. Also, CRAAs caused a significantly higher increase in SOC content in temperate regions (19%) than in subtropical (9.7%) and tropical (12%) regions ( $P < 0.05$ ). In addition, CRAAs were more effective in enhancing SOC content in paddy soils with low nitrogen content (total nitrogen [TN]  $< 1.5\text{g/kg}$ ) or alkaline pH. Further, SOC increased more in the CRAAs with Japonica than Indica rice, increasing 17.8% and 6.1% as compared to their respective rice-monoculture controls. Random forest analysis revealed that animal type was the most important factor influencing SOC under CRAAs. Regression analysis showed that the increase in SOC content had significant positive correlations with soil pH ( $P < 0.01$ ) but negative correlations with mean annual precipitation ( $P < 0.05$ ). Soil TN had significant hump-shaped relationship with on CRAA-driven SOC content. These results indicate that CRAAs can significantly enhance SOC, particularly in low-N, alkaline paddy soils. Our findings suggest that CRAAs with appropriate rice and animal varieties can provide unique opportunities for soil C sequestration, while enhancing farmers' profitability.

### BIO-ORGANIC FERTILIZER IMPROVES SOIL HEALTH IN AN ACIDIC VEGETABLE SOIL IN SOUTHERN CHINA

T. CHANG <sup>1</sup>, S.S. ZHOU <sup>1</sup>, Y.J. ZHANG <sup>2</sup>, H. SHAGHALEH <sup>1</sup>, J. ZHANG <sup>1</sup>, X. YANG <sup>1</sup>, H.J. QIN <sup>1</sup>, M.M. TALPUR <sup>1</sup>, Y. ALHAJ HAMOUD <sup>1</sup>

<sup>1</sup> Hohai University, Nanjing, CHINA

<sup>2</sup> Nanjing Hydraulic Research Institute, Nanjing, CHINA

Soil acidification impairs plant growth and agricultural sustainability, whereas organic fertilizers can ameliorate soil health. Nonetheless, the response of soil health especially microbial populations to bio-organic fertilization in acidified soil remains elusive. This study selected soils that underwent acidification in high tunnels, and native vegetation soils were used as controls. We investigated the effects of the sole application of inorganic fertilizers, sole application of organic fertilizers, and combined application of organic and inorganic fertilizers on the microbial diversity of rhizosphere soils of tomato (*Solanum lycopersicum*, L.), soil chemical and physical indicators. Results indicated that organic fertilizer enhanced bacterial network complexity, metabolic function, and convergence of the community structure of Native soils. Beneficial biomarkers were identified by linear discriminant analysis effect size screening. Soil health assessment results showed that the application of bio-organic fertilizers can increase the physical, chemical and biological fractions of acidified soil, thereby improving soil health.

### IMPACT OF SOIL HEALTH STRESS ON WATER FLUX DYNAMICS IN THE SOIL-PLANT-ATMOSPHERE CONTINUUM

#### Authors

A. K. SALMAN, W. DURNER, M. SUT-LOHMANN

Technische Universität Braunschweig, Braunschweig, GERMANY

Climate change exerts pressure on soil health, with soil salinization being a significant influencing factor. Salinization can occur naturally in arid and semi-arid regions when soil surface evaporation exceeds precipitation, or due to mismanagement of soil and water resources. Climate change-induced factors, such as prolonged precipitation-free periods and sea level rise, extend salinity problems to some humid regions, particularly in coastal areas.

In addition to their impact on soil and plant health and nutrient balance, soluble salts influence water flux within the soil-plant-atmosphere continuum by affecting the hydraulic gradient. Despite this well-known influence, there is a lack of quantitative studies predicting the impact. In this study, we explore the role of changes in hydraulic gradient resulting from soluble salts on evapotranspiration from grass planted in small-scale weighing lysimeters under laboratory conditions. The lysimeters are equipped with soil moisture, potential, temperature, and electrical conductivity sensors.

To create different osmotic conditions, the lysimeters were irrigated with various water qualities, including distilled water and a 4.79 dS/m NaCl solution. The results indicated a significant reduction in cumulative evapotranspiration under osmotic influence, reaching 39% after three months of treatment application. Based on the experimental data, an empirical model has been developed to predict the reduction in actual evapotranspiration under salinity conditions. These results are crucial for improving agricultural water management under salinity stress. However, field-scale studies are essential to validate the findings and develop a robust prediction model.

<sup>4</sup> Instituto de Bosques y Sociedad, Facultad de Ciencias Forestales y Recursos Naturales, Valdivia, CHILE

Land use change is the most substantial human alteration of terrestrial ecosystems, driving environmental impacts associated with the provision of ecosystem services linked to soil resources, strongly affecting the estimation of soil carbon (C) stock. This work evaluates the variation in the soil C stock of different types of volcanic soils in southern Chile, associated with different use conditions, considering the variation in soil shrinkage as a correction factor. For this, allophanic, non-allophanic and crystalline volcanic soils were collected between the La Araucanía Region (38.95°LS) to the Aysén Region (44.03°) of Chile under different uses: Native Forest (NF), Crop (C) and Grassland (G). Chemical indicators were evaluated: pH H<sub>2</sub>O, SOC; and physical: bulk density (Bd), plant available water (PAW), air capacity (AC) and Coefficient of linear extensibility (COLE). Some of the main results show that the pH varied between 4.28 and 6.92 and the SOC ranged between 1.01 and 27.92%, observing a reduction in the soil C stock (1.60 Mg C ha<sup>-1</sup>) due to the change in use NF > C as a result of soil tillage. Bd presented an opposite trend, which varied between 0.14 and 1.18 g cm<sup>-3</sup>. Soil C stock normally protected in soil aggregates reduces soil Bd, while continuous tillage activities reduce soil C stock, increase Bd, and decrease shrinkage capacity. Volcanic soils have the capacity to store 117 Mg C ha<sup>-1</sup> in the first 0.2 m and they are sensitive to changes induced by management. In general, soil C stock estimates are made considering the soil as a rigid body without considering changes in Bd, which could affect the final soil C stock estimate.

### ASSESSING THE IMPACT OF TERRACING ON SOIL HEALTH IN SOUTHERN BRAZIL: A THREE-YEAR STUDY INVESTIGATING SOIL MICROBIAL ATTRIBUTES IN SLOPED AREAS

N. .F. BALAREZO GIAROLA, S. STETS, R. MAZER ETTO, K.V. SZEMOCOVIAK, D. HYEDA, E.A. AGNELLOS BARBOSA, F. TONDELLO BARBOSA, C. WEIGERT GALVAO

STATE UNIVERSITY OF PONTA GROSSA, PONTA GROSSA, BRASIL

Soil health is affected by its genesis and other factors related to soil use and management. Conservation practices provide benefits to the soil, such as reduced erosion, increased organic matter content and, consequently, improved soil quality and agriculture productivity. To evaluate the influence of terraces in non-till areas of Southern Brazil, ten microbiological soil attributes of 72 soil sampled points were evaluated in a principal component analysis during three years. Six months after terrace implementation (2020), it was possible to distinguish areas with and without terraces and to notice that the disturbance caused by terraces increased Basal Respiration (BR) and metabolic quotient ( $qCO_2$ ), induced the disruption of soil aggregates, and facilitated access to plant residues. This stimulated the proliferation and activity of the soil microbiota, leading to a positive correlation between the terraced area and other microbiological attributes, mainly Microbial Biomass Carbon and Nitrogen. In the second year (2021), the separation of the sampled points of the two areas was maintained. In addition, there was a division of the non-terraced area into three groups, indicating the influence of the drainage ramp on the soil microbiological attributes. It is important to highlight that BR, Betaglucosidase activity and  $qCO_2$  showed a strong positive correlation with the area without a terrace indicating higher  $CO_2$  loss to the atmosphere. In the third year (2022), the heterogeneity of the unterraced area continued to be evidenced and most of microbiological attributes showed a positive correlation with the terraced area indicating that the terrace increases microbiological soil quality. Over the three years, there were a homogenization trend of the sampled points of the terraced area and in contrast, the non-terraced area gradually became more heterogeneous. Furthermore, the terrace induced a reduction in the metabolic quotient and an increase in the microbial activity. Our results showed the effectiveness of the terrace in maintaining soil stability and health in sloped areas.

### SOIL QUALITY ASSESSMENT OF ORGANICALLY CULTIVATED PADDY IN SOUTH KOREA

C. LEE<sup>1</sup>, S.M. LEE<sup>2</sup>

<sup>1</sup> National Institute of Agricultural Sciences, WANJU-GUN, JELLABUK-DO, SOUTH KOREA

<sup>2</sup> National Institute of Agricultural Sciences, WANJU-GUN, JELLABUK-DO, SOUTH KOREA

Unlike conventional agriculture which focuses on high productivity, organic agriculture that focuses on promoting biodiversity, producing sustainable crop, and minimizing environmental impact, requires the use of organic materials instead of chemical for soil management. It can affect not only soil chemical property, but also its physical and biological properties. Organic farmland can be considered healthy soil management in that it can achieve not only crop production but also biodiversity and environmental conservation. In South Korea, little research has been conducted on soil quality assessment (SQA) over the past 20 years since the early 2000s. In this study, SQA for organic paddy soil was developed, and the developed SQA was used to evaluate paddy soils quality according to the period of organic farming in South Korea. For healthy soil, we set three main soil functions: provision of biological habitat, production of sustainable crop, and conservation of agricultural environment. Twelve SQ indicators were selected from 18 SQA frameworks from 12 countries: bulk density, water-stable aggregation, pH, organic matter, available phosphate, exchangeable potassium, available silicate, soil respiration rate, and soil enzyme activity (dehydrogenase, b-glucosidase, urease, and phosphatase). Among 12 indicators, reference values were set and scores were assigned based on 5 chemical indicators for which soil database was established in South Korea. Soil quality index (SQI) was evaluated for the average period of organic farming practice as 8 years (12 sites), 3 years (10 sites), and non-organic farming (10 sites). As a result, the biological habitat provision function was high in the order of 8 years (94), non-organic (86), and 3 years (82). There was no difference in crop production function. Environment conservation function was higher in 8 years (66) than 3 years (51) and non-organic (51). Integrated SQI, which applied weight by function, was in the order of 8 years (74), non-organic (68), and 3 years (67). Further research on improvement of the scoring method considering physical and biological indicators is needed.

Fig. 1. Soil quality assessment by organic farming practice period in South Korea. LOF is organic farming long-term practice paddy soil on the average of 8 years (12 sites), SOF is organic farming short-term practice paddy soil on the average of 3 years (10 sites), CON is non-organic farming paddy soil (10 sites).

### COMPARATIVE EXAMINATION OF SOME MICROBIOLOGICAL PROPERTIES OF DIFFERENT CULTIVATED AND NATURAL GRASSLAND SOILS IN EASTERN HUNGARY

M. TÁLLAI, Z. SÁNDOR, I. KOCSIS, T. J. NOVÁK, A. BALLA KOVÁCS

University of Debrecen, Institute of Agricultural Chemistry and Soil Science, Debrecen, HUNGARY

The monitoring of intensively farmed areas and soils is a very important task. In our comparative study, we were examined three different soil types with different cultures based on some microbial properties in the Eastern Hungary region (2019-2021). The examined soil types were calcareous chernozem (Chernozems) with corn (*Triticum aestivum* L.) from Debrecen-Látókép - pH(H<sub>2</sub>O)=6.8; humus sandy soil (Arenosols) from Debrecen - Pallag - pH(H<sub>2</sub>O)=5.8, with fruit (*Prunus cerasus* L.) – and solonetz soil (Solonetz) with grassland Hajdúnánás – Tedej, pH(H<sub>2</sub>O)=6.6. The areas have received only natural rainfall. The moisture content of the soil samples was during the three years average 10-19%. We observed that during the three consecutive years the moisture content in the soil decreased in all three areas. The highest activity of saccharase (SA) (7.21 mg glucose 100g<sup>-1</sup> 24h), urease (UA) (65.34 NH<sub>4</sub><sup>+</sup> mg<sup>-1</sup> 100g<sup>-1</sup> 2h), and dehydrogenase activity (DA) (219.55 µg INTF g<sup>-1</sup> 2h<sup>-1</sup>) was in solonetz soil, which natural uncultivated, pasture. The phosphatase activity (PA) (14.84 P<sub>2</sub>O<sub>5</sub> mg<sup>-1</sup> 100g<sup>-1</sup> 2h) was higher in the chernozem soil, it was almost the same for sand (6.47 P<sub>2</sub>O<sub>5</sub> mg<sup>-1</sup> 100g<sup>-1</sup> 2h) and grass (6.69 P<sub>2</sub>O<sub>5</sub> mg<sup>-1</sup> 100g<sup>-1</sup> 2h). The CO<sub>2</sub> production was 18.44 on the chernozem, 15.65 on the humus sand, and 19.11 mg 100g<sup>-1</sup> 7 days<sup>-1</sup> on the solonetz soil. Regarding the seasonality, the SA and PA was not significantly higher, while UA was significantly higher in spring. DA showed higher activity in autumn, while soil CO<sub>2</sub> production was also in an unprovable way higher in autumn than in spring. Grasslands create a specific environment for the organisms that live in them. The large root masses of grass provide an important source of organic matter for micro-organisms. According this study, the enzyme activity and the CO<sub>2</sub> production were also more intensive on undisturbed pasture soil utilization natural grassland than in soils under intensive cultivations.

### CHANGES OF SOME CHEMICAL PARAMETERS OF SOIL WITH A DEPTH IN A LONG TERM FERTILIZATION AND TILLAGE EXPERIMENT

A. BALLÁNÉ KOVÁCS, R. KREMPER, E. .K. JUHÁSZ, I. KINCSES, Á. BÉNI, M. TÁLLAI

University of Debrecen, Institute of Agricultural Chemistry and Soil Science, Debrecen, HUNGARY

The effects of agricultural management on soil properties in top-soil have been widely studied, but few studies have been examined the effects on sub-soil. In order to determine the impacts of chemical fertilization and different tillages on soil properties in subsoil, soil samples were collected from soil deeper layer in a long-term experiment, where the soil type is Chernozem. Soil samples were taken in the 20th year of the experiment, in the autumn, under maize monoculture from the crop row from 0-100 cm. The treatments were control, NPK fertilization and tillages: plowing tillage (PT), ripper tillage (RT) and strip tillage (ST). In PT sampling were from 0-500 cm deep layer. The fertilization decreased the pH<sub>KCl</sub>, and the values increased with a depth in ST and RT, but did not change in PT. Fertilization increased the available nutrients differently in various tillage systems. The highest CaCl<sub>2</sub>-NO<sub>3</sub><sup>-</sup> was measured in plots with PT, followed by values of ST and RT and the values decreased with the depth until 60 cm, but a NO<sub>3</sub><sup>-</sup> accumulation zone was found along the all 120-400 cm depth. The NH<sub>4</sub><sup>+</sup> concentration decreased with a depth, but there was no accumulation zone in deeper layer. Higher AL-P<sub>2</sub>O<sub>5</sub> and AL-K<sub>2</sub>O were measured in the ST fertilized plots compared to values of PT and RT plots. The soluble P and K decreased with a depth differently. In plots with RT and ST a significantly decrease was measured up to 40 cm, and from that depth the concentration slightly changed. In PT the soluble P and K did not change in the depth of 0-40cm, but from that depth the nutrient concentrations significantly decreased.

In the fertilized plots of PT, ST and RT the Ca, Mg, Zn and Cu concentration were lower compared to the control. The concentration of non-supplied nutrients changed with a soil depth differently; AL-Ca and AL-Mg increased, LE-Zn did not change, and LE-Cu decreased.

<sup>2</sup> Tehran University, Tehran, IRAN, ISLAMIC REP

<sup>1</sup> Aarhus University, Viborg, DENMARK

Soil salinization is a prevalent form of land degradation in arid and semi-arid regions. Classical methods for salinity study are time and cost-consuming and therefore employing new techniques like digital soil mapping has become imperative. This study lays on a foundation of using random forest model for field-scale soil salinity mapping in the central part of Iran in 2018. Field studies were conducted by grid sampling designed for 130 surface samples with 100-meter intervals. Laboratory analysis was performed on samples from two predetermined uses. 1- Abandoned pistachio garden due to lack of water and 2- Pistachio garden with more than 20 years old trees with furrow irrigation system. To explain the SCORPAN equation environmental covariates; spectral indices from Landsat 8 and terrain attributes from DEM were prepared. Recursive feature elimination employed to simplify the model by identifying the most important environmental covariate to make random forest. The most important covariates were normalized difference salinity index, topographic wetness index, Channel Network Base Level, normalized difference vegetation index, and modified soil vegetation index. Based on 10-fold cross-validation random forest predicted soil salinity map with the coefficient of determination value ( $R^2$ ) of 0.56.  $EC_e$  was between 2.58 to 188 dS/m with mean amount 46.95 dS/m. The highest amounts of  $EC_e$  were at the middle of the field, in pistachio trees land use. Approximately 33% of the studied area were in the salinity class 4–8 dS/m, 20% fell in the 8–16 dS/m class, 15% in the 16–32 dS/m class, and 32% in the salinity class greater than 32 dS/m. All the study area was classified as hypersaline soil ( $EC_e > 4$  dS/m) which combination with the hot and arid climate demonstrate the unsuitability of the study area for agricultural purposes. The digital nature of the produced salinity map allows information to be updated at a lower cost and faster on different scales in the future.

<sup>4</sup> UNIVERSITY OF MALAGA, MÁLAGA, SPAIN

<sup>5</sup> UNIVERSITY OF MALAGA, MÁLAGA, SPAIN

Andalusia represents the 86% of the Spanish production. In this region, precipitations are scarce and erratic and limit water availability for irrigation. Meanwhile, there is a risk of saturation of local soils with toxic salts due to the poor quality of irrigation water.

The objective of the study was to investigate impact of irrigation with wastewater on the injury of Avocado leaves. EC of regenerated wastewater 2.3 times more than ground water. There are excess of sodium and chloride in wastewater comparative to groundwater at 6.5 and 7.4 correspondingly. Sodium Adsorption Ratio for groundwater and regenerated water are 8.0 and 51.9.

It is known that avocado develop severe leaf burn if the SAR of the irrigation water is more than about 6 - 10. SAR of the wastewater is 5 times more 10. That is why first way is connected with the regenerated wastewater dissolution with low mineralized natural water follow principle 1:1. The best leaf area yield was fixed in option with ground water. 50 % of regenerated water with ground water dissolution led to decreasing of leaf burn injury to slight level to 52 % cases comparative with 100% regenerated water treatment. The data obtained tell us that avocado leaves growth depression fixed most of all in the 100% treatment. The data on electrolyte leakage and cell membrane stability were obtained in order to determine the injury due to salt stress at a cellular level on the leaves of the avocado. It was established that lowest level of three pigments (Chlorophyll a, b and Carotenoids) was established in the treatment with 100% regenerated water. 50% level using of mix consisted of ground and regenerated water (50/50) take intermediate indexes. The similar estimation was made after calculation of Chlorophyll a+b/ Carotenoids ratio in the avocado leaves ratios. The less meanings of ratio between Chlorophyll a+b and carotenoids were fixed in the treatment with regenerated waste treatment 100% option.

The use of cover crops in agricultural cultivation may enhance soil health. A field experiment was conducted to determine the effects of winter-planted cover crops and no cover crops on soil health of organic vegetable production systems in humid environments. The cover crop treatment consisted field peas + winter rye+ hairy vetch. Soil physical, chemical, and biological properties were tested to quantify soil health. Cover crops reduced soil bulk density, and increased soil organic carbon, total nitrogen, extractable phosphorus, extractable potassium, available water content, saturated hydraulic conductivity. Based on the analytic hierarchy process, correlation analysis and expert's opinion method, soil indicators were screened and soil health assessment was conducted. Cover crops improved the soil health scores. The results can provide fundamental reference for farmers to apply cover crops in agricultural land use for improving soil health in the Southeast United States.

### SOIL AGGREGATE STABILITY IMPROVEMENT WITH DIFFERENT ORGANIC AMENDMENTS IN AN AGRICULTURAL SOIL OF CHINA

J. ZHANG, Q. WU, T. CHANG, X. LIU, D. ZHOU, W. TAO

College of Agricultural Science and Engineering, Hohai University, Nanjing, CHINA

Aggregate stability is a commonly used indicator of soil health. Soil physical properties plays an important role in soil nutrient absorption, microbial activity and plant healthy growth. Soil management measures significantly affect soil organic matter content and aggregate size distribution. Therefore, the study of soil aggregate distribution characteristics, soil organic matter content and tomato yield under different organic amendments is of great significance for the study of soil structure. Tomato pot experiment was carried out with yellow brown loam soil in dry land as test soil. A total of eight treatments were set up: 1% biochar (B1), 3% biochar (B3), 5% biochar (B5), 3% earthworm castings (V3), 5% earthworm castings (V5), 0.1% mineral source potassium fulvic acid (F1), 0.2% mineral source potassium fulvic acid (F2), and control without amendment (CK). Biochar and earthworm manure treatment can effectively reduce soil bulk density and increase total soil porosity. The organic matter content of B5 was the highest, reaching 21.89g·kg<sup>-1</sup>. The particle size of soil aggregates treated by biochar is mainly 0.053~0.25mm, the particle size of V3, F1 and F2 is mainly > 0.25mm, and the stability of V3 aggregates is the best. Biochar, earthworm castings and mineral source potassium fulvic acid can promote tomato yield increase, among which F2 and V3 yield increase effect can reach more than 30%. The correlation analysis showed that the geometric mean diameter was significantly positively correlated with the mean weight diameter and the water stable macroaggregate content. The application of organic amendments can effectively improve the physical and chemical properties of yellow brown loam soil, promote the formation of large aggregates, improve the stability of aggregates, and promote the yield increase of tomato. Among them, the comprehensive effect of adding 0.2% mineral source potassium fulvic acid is the best, which has good application potential.

### ORGANIC AMENDMENTS AFFECT SOIL HEALTH INDICATORS FOR SUSTAINABLE LAND MANAGEMENT

T. CHANG <sup>1</sup>, S.S. ZHOU <sup>1</sup>, Y.J. ZHANG <sup>2</sup>, J. ZHANG <sup>1</sup>, A. HAMAD <sup>1</sup>, H. SHAGHALEH <sup>1</sup>, Y. ALHAJ HAMOUD <sup>1</sup>

<sup>1</sup> Hohai University, Nanjing, GHANA

<sup>2</sup> Nanjing Hydraulic Research Institute, Nanjing, CHINA

The application of organic amendments to agricultural land is an important way to reuse organic waste. Organic amendments can improve soil quality, thereby producing a series of environmental and agricultural benefits. Different organic amendments (calcium lignosulfonate, bio-organic fertilizer, and biochar) were used to remediate an acid soil caused by excessive use of chemical fertilizers. In addition, two irrigation amounts (conventional irrigation and deficit irrigation) were set. We measured soil physical properties (bulk density, total porosity, field water capacity, wilting coefficient, soil available water, soil aggregates) and chemical properties (pH, available nitrogen, available phosphorus, available potassium, redox potential, exchangeable magnesium, exchangeable Calcium, total organic carbon, dissolved organic carbon, easily oxidizable organic carbon). Research findings can provide reference for the utilization of organic amendment to alleviate soil acidification under different irrigation systems.

### HOW DOES MANAGEMENT OF DUAL-USE PERENNIAL GRAIN SYSTEMS AFFECT SOIL AGGREGATE STABILITY?

B.I. MONTANO RODRÍGUEZ<sup>1</sup>, A. DE CAMARGO SANTOS<sup>1</sup>, B. ROBINSON<sup>1</sup>, S. TAJIK<sup>1</sup>, S. CULMAN<sup>2</sup>, L. DEISS<sup>1</sup>

<sup>1</sup> The Ohio State University, Wooster, USA

<sup>2</sup> Washington State University, Pullman, USA

Perennial grain systems can help increase soil aggregate stability, which is a soil health indicator that plays a prominent role in building soil structure and storing organic carbon occluded within aggregates and pore networks. The objective of this study was to evaluate the effect of forage defoliation intensity in dual-use perennial grain systems on soil aggregate stability. Soil samples were collected from the 0-20 cm depth at the fourth year after establishment of Kernza Dual-Use experiments in two locations in Ohio. Trials were planted with the commercially available variety Clearwater Kernza (1504) in a randomized complete block design with four replicates and included four defoliation treatments (forage harvests) at: (i) Summer after grain harvest, (ii) Spring+Summer; (iii) Fall+Summer (iv) Spring+Summer+Fall. Soil wet aggregate stability was determined using nested sieves submerged in water to disaggregate soil through shaking. Oven-dried soils were initially sieved to particle size <8mm, then laid on top of a stack of four sieves with different opening sizes (2000, 500, 250, and 53 microm), ordered bottom-up from the smallest to the largest opening. The stack of sieves was repeatedly submerged into a bucket filled with water, for 10 minutes in 2 seconds intervals. This process was used to determine the proportion of soil-stable aggregate that remained at each sieve size. We found that there were no differences among defoliation treatments over the size and distribution of the aggregates in dual-use perennial grain systems. These results represent an opportunity for growers to sustainably intensify forage harvesting in perennial grain systems, while maintaining the productivity potential and health of these systems.

Method of Yoder (1936) to determine aggregate stability in a dunker machine

## 4. Soil health in achieving the Sustainable Development Goals 4.14 133547 - Landuse change impacts on soil health

**EFFECT OF DIFFERENT SOURCES AND DOSES OF NITROGEN, FOLLOWING TWO DIFFERENT RECOMMENDATION SYSTEMS, ON THE DEVELOPMENT OF CORN AND COMMON BEANS**

J.M. DE SOUZA ALMEIDA

Federal University of Goiás (UFG), School of Agronomy, Department of Soils, Goiânia/GO, BRAZIL

The ONU released data that the global population jumped to 8 billion people in 2022 and projections are that these numbers will reach 9 billion in 2037. Given this scenario, food uncertainty, which already affects 260 million people in the world, increases even further and along with it sustainable production alternatives are necessary. Brazil is one of the largest producers of corn and beans in the world; For such production to be possible, the use of fertilizer on a large scale is essential. A viable strategy is to combine the rational use of fertilizers with sources that are more usable by plants. The objective of the work was to evaluate the performance of nitrogen sources in the production of corn and beans based on two more recent soil correction systems and recommendations available for the central Brazilian region. The experiment was conducted in a greenhouse at the Federal University of Goiás, Goiânia-GO, Brazil, on corn and bean crops. The experimental design was completely randomized, with 8 treatments with 5 replications and two controls with 4 replications each, for both cultures. They are: Urea, Nitratop, Nitratop + DMPSA and Super N Pro for both the Boletim 100 recommendation system and the Cerrado recommendation system. The evaluations carried out were: biometric, physiological, fresh mass, dry weight, nutrient export analysis and protein content in the plant tissue of corn and bean grains. The data were subjected to analysis of variance, Tukey test at 5% significance. Bulletin 100 was the recommendation system that showed the greatest result in production for corn, while for beans it was the Cerrado, while the Nitratop + DMPSA treatment was the best source for both crops.

### IMPACT OF TOPSOIL MINING FOR UNFIRED MUDBRICKS ON SOIL QUALITY IN EASTERN KWAZULU-NATAL, SOUTH AFRICA

N. DUBE, G. LESHALAGAE

University of KwaZulu-Natal, PIETERMARITZBURG, SOUTH AFRICA

The depth of topsoil is a significant parameter in determining soil quality (Brunel et al. 2011). Unfortunately topsoil mining for unfired bricks is widespread in most grassland areas of rural South Africa. Despite, extensive research on erosive forms of soil degradation, less attention has been given to non-erosive forms associated with land uses such as topsoil mining for mudbricks. This study therefore assessed the impact of topsoil mining associated with unfired mud bricks on selected soil quality indicators in two villages of KwaZulu-Natal, South Africa

First, local miners were interviewed to ascertain information related to topsoil mining, brickfield site identification and soil suitability for mud bricks. Two brickfields per village mined for less or equal to 5 and more than 20 years, respectively were used in this study. Experiment consisted of three treatments, that is, unmined, mined and recovering lands replicated three times. Nine soil samples were collected (0–10 cm) from each site (three composite samples per treatment) with corresponding bulk density samples taken at 0–5 cm using core rings. Soils were air-dried and sieved through a 2 mm sieve (except for soil samples used for aggregate stability) prior to fertility assessment.

The average topsoil mining depth was 30 cm. Topsoil mining increased silt fraction across all studied brickfields with an average of 45.2% in mined compared with 30.6% in unmined treatments. The response of clay fractions was variable across villages and mining time. Mining significantly decreased mean weight diameter, exchangeable bases, organic carbon, and nitrogen content and stocks and porosity while it increased bulk density.

Topsoil mining for mudbricks results in poor soil physical quality, nutrient availability and carbon storage with implications for land degradation in mud brickfields.

<sup>5</sup> State Key Laboratory of Soil Erosion and Dryland Farming on the Loess Plateau, Institute of Soil and Water Conservation,, XIAN, CHINA

Soil stability serves as an indicator of soil health. This study examines disruptive mechanisms across forest, shrubland, and grassland covers, assessing four methods (modified Yoder MYOD, Le Bissonnais LB, Slakes App SI, and Ultrasonic agitation UA) across 0–20 and 20–40 cm soil layers to elucidate their impact on soil stability. Our investigation reveals notable disparities in aggregate stability among land covers. The results of MWD (Yod) indicated that surface and subsurface soils were in the range of 1.23–2.86 mm, which accounted for medium (0.8–1.3 mm) to very stable (>2 mm) soils. In LB tests, fast wetting (FW) demonstrated the most pronounced soil instability (MWD: 0.45 mm) followed by WS (Wet stirring) and SW (Slow wetting). Notably, the SI unveils varying stability levels, with values ranging from 0.17 to 15.08 SI. Furthermore, specific dispersion energies (SE) by the UA method showcase a diverse spectrum of soil stability responses. SE values at different stages of aggregate disruption spanned from SE10 (8.1 to 29.4 J/g), SE50 (53.0 to 193.4 J/g), and SE90 (176 to 642 J/g). Correlation analyses highlighted the significant influence of soil organic carbon (SOC), total nitrogen (TN), fine root biomass, clay content, and soil water content (SWC) on soil stability. Despite methodological variances, strong positive correlations between stability parameters and methods underscore the reliability of these assessment techniques for all types of soils. Furthermore, our findings suggest that soil under forest and shrub exhibits the highest and lowest stability, respectively. Intriguingly, despite the diverse breakdown mechanisms employed by each method, results indicate their equal efficacy in stability assessment, with some distinctions and limitations. Our study provides crucial insights into soil stability dynamics, underlining the necessity of comprehensive assessment methods to enhance our understanding of soil health.

### REGENERATIVE FARMING – THE NEW APPROACH TO RESTORE AND IMPROVE SOIL HEALTH

B. HOUSKOVA

NPPC - VUPOP, Bratislava, SLOVAK REPUBLIC

At present time there is an ever-increasing need to change soil cultivation practices from conventional to more ecological variants—the need to use agricultural land in a sustainable way. Sustainable farming practices refer to methods of agricultural production that are environmentally responsible, economically viable, and socially equitable. One of the most important aims of these practices is to minimize negative impacts on the environment while maintaining the land's long-term productivity together with ecosystem services and soil functions. Sustainable farming emphasizes soil conservation, water management, biodiversity preservation and increase, ethical treatment of farm workers, and adaptation to climate change. Sustainable farming practices include agroforestry, crop rotation, integrated pest management, organic farming, the use of renewable energy sources, and regenerative farming. Soil is an integral part of the environment. By adopting sustainable farming practices, farmers can contribute to a healthier environment and more resilient agricultural systems. Regenerative farming is an approach to agriculture that focuses on improving and restoring soil health and ecosystems. It involves practices such as minimal tilling, cover cropping, crop rotation, and the use of natural fertilizers to build and maintain soil health and fertility. This method aims to sequester carbon, increase biodiversity, and reduce the use of synthetic agents. Regenerative farming, following the principles of sustainability also emphasizes the importance of holistic land management, water conservation, and good agricultural practices to generate resilient, productive farming systems.

<sup>3</sup> Institute of Soil and Water Conservation, Northwest A&F University, Yangling, CHINA

Sustainable agricultural practices have become a major challenge for achieving more rational and efficient utilization of arable land resources in recent years. Organic farming has been promoted by farmer cooperatives to gain organic agricultural products and prevent soil degradation. However, further evaluation is needed to determine whether organic agriculture dominated by cooperatives can effectively improve soil health. Soil health under the organic management system of cooperatives was compared with the conventional management system of smallholders in southeastern China with 39 physical, chemical, biological, and environmental indicators. Results showed that the cooperative-dominated organic management system showed higher stability of aggregates, soil organic matter (SOM), available nutrients, and microbial biomass. It also significantly altered the structure of microbial communities. The soil fertility index and biological index were respectively 36.5% and 24.2% higher under the organic management system of cooperatives as compared to the conventional management system of smallholders. However, there was no significant difference in soil environmental indices between the two management modes. Edaphic indicators of bulk density, penetration resistance, mean weight diameter, SOM, dissolved organic carbon, earthworm biomass, gram-negative bacteria, and bacteria were identified by network analysis as key indicators of soil health assessment. The cooperative management system significantly enhanced soil health by 23.38% by improving soil structural stability, total and active organic carbon, and quantities of soil fauna and microorganisms. Additionally, the farmland quality index and soil health index based on all soil health indicators under the cooperative management system were respectively 4.2% and 38.3% higher than under the conventional management system. Overall, the organic agriculture system, which was dominated by cooperatives, could enhance soil health by ameliorating soil physical, chemical, and biological properties. Our findings aimed to unravel the significant contribution of organic farming under cooperatives towards enhancing soil health in intensive agricultural systems.

### INVERTEBRATE RECOLONIZATION THROUGH PHYTOREMEDIATION IN A HEAVY METAL POLLUTED SOIL

B. MANACHINI <sup>1</sup>, A. CORSINI <sup>2</sup>, P. ZACCHEO <sup>3</sup>

<sup>1</sup> Department of Agricultural, Food and Forest Sciences (SAAF), University of Palermo,, Palermo, ITALY

<sup>2</sup> ISS di Codogno sede Engardo Merli, Lodi, ITALY

<sup>3</sup> Department of Agricultural and Environmental Sciences - Production, Landscape, Agroenergy. University of Milano, Milano, ITALY

Sites polluted by inorganic wastes can be successfully remediated by plants to immobilize contaminants (phytostabilization) or to extract them from soil (phytoextraction). The addition of organic matter is a common practice to facilitate vegetation of inorganic substrate by improving soil physical and nutritional properties and sustaining soil biological activity. Phytoremediation field experiments were carried out on a soil/pyrite cinders mixture amended with manure. After that three different plants were considered *Arundo donax* L., *Helianthus annuus* L., and *Sorghum bicolor* L. for phytoremediation. The course of remediation was evaluated through chemical analysis, plant bioassays, and soil invertebrate analysis. The effect of heavy metal pollution and the success of the 3 different remediation strategies on the soil fauna community, and the soil food web were assessed by evaluating nematode community composition, functional guild abundances and diversity, maturity and soil food web indices, and QBSar in polluted soils in TorViscosa (Udine, Italy). Soil content of Pb, Ni, Cu, and Zn, soil pH, and soil texture were measured. The invertebrate community and diversity indices were strongly affected by metal soil content. Initially, the soil was almost a biological 'desert' with really few animal taxa. The data suggests that manure could affect the nematode community and other invertebrates not only by improving bacterial activity but also by introducing new nematode genera relative to the environment. Moreover, the phytoremediation procedures allow a further recolonization of the soil by invertebrates especially in the *A. donax* fields.

### MICROMAPPING OF BACTERIAL COLONIZATION ON ORGANIC AND MINERAL COMPONENTS: AN APPROACH TO STUDY SOIL BIOFILMS

T. GONZÁLEZ VARGAS <sup>1</sup>, M.C. GUTIÉRREZ CASTORENA <sup>1</sup>, C.A. ORTIZ SOLORIO <sup>1</sup>, J. DELGADILLO MARTÍNEZ <sup>1</sup>, E.V. GUTIÉRREZ CASTORENA <sup>2</sup>

<sup>1</sup> PROGRAMA DE EDAFOLOGÍA, COLEGIO DE POSTGRADUADOS, Texcoco, MEXICO

<sup>2</sup> FACULTAD DE AGRONOMÍA, UNIVERSIDAD DE NUEVO LEON, Escobedo, MEXICO

Soil biofilms play important roles in ecological processes such as carbon cycling. However, little is known about the spatial distribution of soil biofilms at the microscopic level using thematic micromaps. Therefore, the aim of this study was to analyze the spatial distribution of bacterial colonization in different degrees of decomposition of organic matter and in the mineral fraction at the microscopic level using thematic maps. Unaltered soil samples were collected in Andosols in the O-layers and in the O-A transition horizons. Sequential images were captured from the soil thin sections to construct high-resolution mosaics in plane-polarized light (PPL), cross-polarized light (XPL), and ultraviolet light (UVL). Classification models were applied to obtain thematic maps of the components studied. The degree of association was evaluated and quantified using geoprocessing tools and according to three levels of colonization area I: 1-100  $\mu\text{m}^2$ , II: 100-1 000  $\mu\text{m}^2$ , and III: > 1 000  $\mu\text{m}^2$  or biofilms, . The results suggest that bacterial communities do not associate randomly. Instead, they are associated with specific components depending on the horizon. Bacteria form biofilms on lightly decomposed organic matter in the O horizons. In contrast, in the O-A horizons, microbial colonies are associated with the highly decomposed class and the mineral fraction, but only at colonization levels I and II. This research provides a new approach to studying soil biofilms by establishing and quantifying spatial relationships with organic and inorganic components using high-resolution micromaps.

Knowledge of the biodiversity in vineyard soils is a prerequisite and it is as important as the most studied characteristics.

The characterization of microbial communities and soil arthropods is not part of the routine analyses carried out by farmers to correctly set up cultivation operations, although attention to this parameter is gradually increasing. However, data are still rather scarce.

The Attiv-aree - Oltrepò Biodiverso project, founded by the Cariplo Foundation, has enabled sampling to be carried out in 6 vineyards in Oltrepò Pavese with different inter-row management (permanent grass cover - PGC, tillage - T, alternate tillage - AT), using a multidisciplinary approach. Oltrepò Pavese is the largest wine-producing area in the Lombardy region, with over 12,000 hectares of vineyards (2021), and this study on soil biodiversity is the first of its kind.

The soil samples were analyzed to determine chemical, physical and geological properties. Bacterial and fungal communities were detected by NGS analysis of 16S and ITS1 DNA barcodes. The Arthropods were characterized using the QBS method and the biodiversity indices were calculated.

The results of the 2017 sampling allowed a “snapshot” of the communities in these soils. Bacterial communities are more dominant than the Fungi and Archaea about the number of species identified, while the total number of species appears to be significantly higher in AT soils than in T soils, PGC soils showing intermediate values.

The Phyla of Bacteria that are significantly more abundant are Proteobacteria, Actinobacteria and Bacterioides; the least represented are Nitrospirae, Planctomycetes, TM7 and W3.

The most abundant fungal Phylum is the Ascomycota, while the least abundant is the Mortierellomycota. The PGC soils were found to be significantly more populated by Fungi than the AT and T soils, which did not differ significantly.

Regarding the total number of Arthropods collected, no significant differences were observed between PGC and T soils. The average QBSar values were rather high (>140) in all types of soil management.

### SOIL MICROARTHROPODS RESPONSE TO PLASTIC DEBRIS AND SOIL CONDITIONS IN OLIVE TREE GROVES

F. LUGARI <sup>1</sup>, C. JACOMINI <sup>1</sup>, K. KARKANORACHAKI <sup>1</sup>, H.-. ESPERANZA <sup>1</sup>

<sup>2</sup> ISPRA/SNPA, Rome, ITALY

<sup>3</sup> Technical University of Crete, Chania, GREECE

<sup>4</sup> MINAGRIS project, Wageningen, THE NETHERLANDS

One of the big questions in soil sciences originates from the definition of soil quality, thus, from the definition of the best soil quality indicators. It is well documented that some taxa of soil fauna are essential components of soil fertility and that an excessive plastic use in agriculture leads to a reduction in the vital functions of soil fauna, in some cases causing their death, due to greater densities of meso-, micro- and nano-plastics; although more detailed research is still needed. This study aims to indirectly provide data on the toxic effects of these plastic fragments on soil fertility by using the QBS-ar and microarthropods abundance as indicators in six olive groves in the province of Chania, Crete: one of the experimental locations of the H2020 international and multidisciplinary project, MINAGRIS, to which this research is addressed. Since these methods have never been used before together to evaluate plastic effects on soil fertility, this experiment attempted to assess the feasibility of QBS-ar and abundance in this emergent scientific area. Therefore, microarthropods communities have been analyzed by extracting micro- and mesofauna for 12 days in Berlese-Tullgren funnels from two different groups of fields: 3 olive groves where plastic is used several months per year, and sometimes left onto the soil for months, and 3 olive groves where no plastic is used. All the 6 groups have similar chemical and physical characteristics. Furthermore, in every field, 3 samples (10 cm<sup>3</sup> each) were collected. Then, by a bimestrial ecomorphological analysis, the presence/absence of the QBS-ar taxa has been researched and, at the same time, their abundance as well.

Systematic monitoring of soil biodiversity and soil health is still in its infancy in Europe. In this project (BodenBiodiv) we build on existing biodiversity monitoring programs in Austria that focus on aboveground biodiversity but do not take soil biota into account (such as the BINATS Biodiversity-Nature-Safety or ÖBM-K Austrian Biodiversity Monitoring of the Cultural Landscape projects). The aim of the BodenBiodiv project is to determine the causes of various indicators of soil biodiversity in the agricultural landscape. The project covers three objectives. First, a systematic monitoring of earthworms in the agricultural landscape will be established in 200 quadrants (625 x 625 m) throughout Austria, in which arable and/or grassland areas will be sampled. Lists of the earthworm species present, their abundance and biomass as well as a distribution map will be compiled. In addition, a manual for future surveys on national monitoring of soil biodiversity will be compiled using harmonized terminology as a supplement to the existing monitoring manuals in Austria. Secondly, we will analysis factors that determine the occurrence of earthworms. Therefore, site characteristics (land use, altitude, climatic variables) and soil properties (pH value, nutrient concentrations, moisture content, carbon content, soil microorganisms) will be linked to the recorded earthworm parameters. Thirdly, a Red List of earthworms for Austria will be compiled on the basis of historical and current data and expert opinions. BodenBiodiv also makes it possible to estimate the influence of climatic variables on soil biodiversity. By incorporating data from existing biodiversity monitoring programs, we can expand our understanding of the interactions between below-ground and above-ground biodiversity.

### EARTHWORMS OF GEORGIA AND THEIR SPECIES COMPOSITION

M. KOKHIA, O. GORGADZE, D. NEBIERIDZE, M. LORTKIPANIDZE, M. KUCHAVA  
Iliia State University, Institute of Zoology, Tbilisi, GEORGIA

Biologically, soil ecosystems support a diversity of soil fauna, including micro- and macrofauna. Appropriate caution is necessary when choosing organisms for use as bioindicators.

Taking into account the worldwide importance of the problem of improving the quality of agricultural and food products, the interest of scientists in improving and recultivating soils is quite understandable. This explains the purpose of this work, which tries to show the results of research conducted to study soil inhabitants and their life activities in Georgia. The importance of earthworms' life activity in the processes of soil improvement and formation is well known. Earthworms are one of the most important groups of soil inhabitants, affecting the structure and chemical properties of the soil. That's why interest in studying this group is rising day by day. The long-term faunal studies show that the species composition of earthworms in Georgia is represented by 89 species belonging to 13 genera. The genus *Dendrobaena* stands out for its species diversity: 26 species (29.21%), the second genus *Allolobophora* with 16 species (17.98%), and the third genus with 12 species (13.5%) is *Eisenia*. About 46 species of earthworms registered in Georgia (51.7%) are recognised as endemic species of the Caucasus (Kvavadze, 1999). High endemism of Caucasian earthworms is induced by the climate in the Caucasus region.

Turkish earthworms show strong similarity to the fauna of Georgia (34 taxa, 40.96%) (Misirlioglu et al., 2018). Of the 18 species distributed both in Georgia and Turkey, the majority belong to Caucaso-Anatolian categories, and all of them belong to the genera *Dendrobaena*, which make this region one of the most important centres of endemism of these genera (Omodeo, Rota 1999, Csuzdi et al. 2006). Considering the growing interest, it was decided to investigate the species diversity in several Georgian reserves: Algety, Mariamdzvany, Kintrishi, Sataplia, Borjom-Kharagauli, Lagodekhi, Vashlovani and Saguramo Natural Reserves. Based on the fact Algeti Nature Reserve is the most inhabited by earthworms.

### RESEARCH ON THE INFLUENCE MECHANISM OF BIOMASS MATERIALS ON NITROGEN TRANSFORMATION IN SALINE SOIL

J. ZHAO, C. YIN

Inner Mongolia Academy of Agriculture and Animal Husbandry Sciences, Hohhot, CHINA

Aiming at the current situation of soil salinization barriers in Hetao Irrigation District, which restrict crop quality improvement and nutrient efficiency. Through indoor cultivation experiments with different biomass materials and fertilizer dosages, combined with indicators such as mineralization rate and nitrification rate, Revealed the mechanism of biomass materials on nitrogen transformation in saline farmland under different salt environments. The research results indicate that: (1) Within 0-3 days of cultivation, the nitrogen mineralization rate of various treatments in saline soil of different degrees decreased rapidly. Adding straw and biochar can both increase the mineralization rate of slightly and moderately saline alkali soil in the early stage of cultivation, but it will inhibit the mineralization rate of slightly saline soil in the later stage, and has no significant effect on the mineralization rate of moderately saline soil in the later stage of cultivation. The addition of straw and biochar has a promoting effect on nitrogen mineralization in severely saline soil throughout the entire cultivation period; (2) Within 0-7 days of cultivation, the nitrogen nitrification rate of mild saline alkali soil gradually increased, followed by a downward trend. Moderately saline soil showed a gradual decrease throughout the entire cultivation period. Adding straw will inhibit nitrification in the whole incubation period of mild and severe salinized soil, and nitrification in the early incubation period of moderate salinized soil, thus increasing the soil ammonium nitrogen fixation. Adding biochar can promote nitrification in mild and severe salinized soil, inhibit nitrification in moderate salinized soil, and increase soil nitrate nitrogen content. Adding straw will inhibit nitrification in the whole incubation period of mild and severe salinized soil, and nitrification in the early incubation period of moderate salinized soil, thus increasing the soil ammonium nitrogen fixation. The research results can provide technical support for nitrogen fixation and emission reduction and development and utilization of reserve land resources in saline and alkaline farmland along the Yellow River.

### USING SOIL MICROORGANISMS TO IMPROVE THE FERTILISER CAPACITY OF ANAEROBIC DIGESTATE

C. VAN MIDDEN<sup>1</sup>, J. HARRIS<sup>1</sup>, E. SHAW<sup>2</sup>, T. SIZMUR<sup>2</sup>, M. PAWLETT<sup>1</sup>

<sup>1</sup> Cranfield University, School of Water Energy and Environment, Bedford, UNITED KINGDOM

<sup>2</sup> University of Reading Department of Geography and Environmental Science, Reading, UNITED KINGDOM

Anaerobic digestate is a nutrient rich slurry by-product derived from biogas production, often used as a fertiliser due to its high nitrogen content. However, nitrogen losses from its application can lead to environmental pollution. In a laboratory experiment, the addition of high organic carbon materials to digestate-amended soil as a potential means to stimulate microbial immobilisation of digestate supplied nitrogen was investigated. Soil was incubated in pots for five months with digestate (equivalent to 250kgN/ha). The impact of adding carbon into the digestate (equivalent to 540kgC/ha) as either glycerol, straw, woodchip, or biochar on soil microbial and chemical parameters was quantified. Glycerol amended soils had significantly higher microbial biomass compared to digestate alone during the first month and at 30 days after application had a 4x higher on average microbial N. The digestate+straw treatment resulted in a significantly greater nitrogen immobilisation compared to digestate alone after three months of incubation. The digestate+woodchip had a 2x higher mean microbial N after 5 months, whilst the biochar amendment did not stimulate significant nitrogen immobilisation at any time. These results suggest that mixing a labile to moderately labile organic carbon amendment, such as straw, with digestate has the greatest potential to reduce nitrogen losses following digestate application through microbial immobilisation.

<sup>4</sup> Agriculture and Agri-Food Canada, Lacombe, CANADA

Mitigating greenhouse gas (GHG) emissions and preserving soil carbon are both imperative for ensuring the success of sustainable crop production. The importance of understanding the relationship between GHG emissions and soil carbon are heightened in nonconventional agriculture practices, such as organic farming, where we are still unclear of the comprehensive ecological effects. Organic farming has many environmental benefits that are not present in conventional agriculture systems, making it a potentially valuable alternative. In order to address climate change and food security for future generations, we first must have an understanding of the complete effects of organic agriculture. Our research aims to identify a cropping system that will reduce GHG emissions during the organic transitional period while estimating the effects on carbon sequestration. Our hypothesis is that within a transition to organic agriculture management, conventional tillage will have an increased loss of carbon to the atmosphere as greenhouse gas, when compared to reduced tillage and integrated crop-livestock systems. This presentation covers the results from our ongoing field experiment in Lacombe, Alberta, Canada, which aims to quantify the effects of three cropping systems on soil carbon and GHG emissions. A fully-phased crop rotation study with a randomized complete block design with four block replicates was established to evaluate conventional tillage, reduced tillage, and an integrated crop-livestock system. Weekly gas sampling using the gas chamber method has been conducted to determine nitrous oxide, methane, and carbon dioxide fluxes. To understand nutrient dynamics in the system, soil samples will be analyzed for carbon, total nitrogen, nitrate, and ammonium concentrations. Results for cumulative fluxes in each treatment were determined throughout the first growing season during the transition to organic management, and these results will be discussed and interpreted during this presentation.

Tillage system	Spring	In-season (optional)	Fall	Total in one growing season	Total in a four-year rotation
1 Conventional tillage system	All crop phases: • Cultivation • A rod weeder	All crop phases: • Rotary hoe (when necessary)	All crop phases: • Cultivation	All crop phases: 3 passes + optional in-season	12 passes + optional in-season
2 Reduced tillage system	All crop phases except the second year GM phase: • Cultivation • A rod weeder	Only wheat and pea phases: • Rotary hoe only (when necessary)	No cultivation	Wheat and pea phases: 2 passes + optional in-season Oat with underseded sweet clover phase: 2 passes The second year GM phase: No cultivation	6 passes + optional in-season
3 Integrated crop-livestock system	Wheat and the first year of the three-year GM phases: • Cultivation • A rod weeder	Wheat phase: • Rotary hoe (when necessary)	Wheat phase: • Cultivation	Wheat phase: 3 passes + optional in-season Three-year GM phase: 2 passes only in the first year of the GM phase	5 passes + optional in-season

### METHANE EMISSION FROM PADDY FIELD AS INFLUENCED BY DIFFERENT IRRIGATION AND NITROGEN TREATMENTS

F. LI, C. MA

Guangxi University, NANNING, CHINA

Reasonable water and nitrogen management is an effective way to reduce methane (CH<sub>4</sub>) emission in paddy fields. In order to reveal the water and nitrogen management mode for reducing CH<sub>4</sub> flux in paddy fields and the influencing factors of CH<sub>4</sub> flux, field experiments were conducted to investigate the CH<sub>4</sub> flux, soil organic acid content and the composition and abundance of microbial community under different irrigation and nitrogen treatments, and then the relationships between CH<sub>4</sub> flux and organic acid content and the composition and abundance of microbial community were analyzed. (1) RI (ridge irrigation) and AI (alternate wetting and drying irrigation) can reduce CH<sub>4</sub> emission compared with CI (flooding irrigation), and the CH<sub>4</sub> emission in CU (40% controlled release urea replacing normal urea) was lower than that of NU (normal urea). (2) Under CI mode, NU decreased the oxalic acid content by 17.3% compared with CU. Under NU treatment, AI decreased the tartaric acid content by 25.9% and 27.4% compared with CI and RI, and the citric acid content by 13.6% compared with RI, respectively. (3) CO<sub>2</sub>-reduction methanogenesis pathway driving from *Methanosarcina barkeri* was the key pathway and core specie of CH<sub>4</sub> production. AI can reduce CH<sub>4</sub> emission more effectively than RI by inhibiting the growth of *Methanosarcina barkeri* in paddy soil. (4) The contents of oxalic acid, tartaric acid, malic acid and fumaric acid contents in soils significantly affected CH<sub>4</sub> flux in paddy field. Thus AICU treatment was a suitable mode of water and nitrogen management to reduce CH<sub>4</sub> emission.

## 4. Soil health in achieving the Sustainable Development Goals 4.16 133568 - Managing soil carbon and nitrogen for climate-smart and sustainable agriculture

### THE EFFECT OF INCORPORATION, SURFACE APPLICATION AND INHIBITOR USAGE ON AMMONIA EMISSIONS APPLYING UREA FERTILIZER ON SANDY SOIL

E. TOTH, M. DENCISO, K. POKOVAI, M. MAGYAR

Institute for Soil Sciences, HUN-REN Centre for Agricultural Research - Department of Soil Physics and Water Management, Budapest, HUNGARY

In 2016, the EU adopted the National Emissions reduction Commitments Directive (NEC Directive), which includes emission reduction obligations for ammonia (NH<sub>3</sub>) for all European country. As agriculture is responsible for 95% of NH<sub>3</sub> emissions, this target cannot be achieved without more efficient use of fertilizers and accurate measurement and assessment of the impact of different factors on NH<sub>3</sub> emissions.

We set up two experiments, where we investigated the NH<sub>3</sub> emission after using urea as fertilizer at two different doses (150 and 180 kg ha<sup>-1</sup> Nitrogen active ingredient). In a laboratory experiment we examined the effect of incorporation, surface application and usage of inhibitor, and in a filed pot experiment the effect of inhibitor usage was studied. For both experiment, sandy soil was used (humus content: 0.78 and 0.79 % at 0-20 and 20-40 cm depth, respectively).

In the laboratory experiment NH<sub>3</sub> emissions (after surface application, without inhibitor) reached a maximum in four days and then started to decrease. In contrast, when the inhibitor-treated fertilizer was applied, the peak was slightly delayed, occurring only on the sixth day. The usage of inhibitor reduced most effectively soil NH<sub>3</sub> emissions, with the magnitude of emissions in these treatments being comparable to the control treatment (where no urea applied). In the case of the surface application of non-inhibitor-treated urea, even a 30 kg ha<sup>-1</sup> increase in active ingredient resulted in a significantly detectable difference in soil NH<sub>3</sub> emissions.

In the field pot experiment, we found that after application of urea fertilizer, NH<sub>3</sub> emission increased significantly compared to the pre-fertilization condition, and this increased NH<sub>3</sub> emission lasted for about two weeks.

In the first week, the average NH<sub>3</sub> emission was highest in the 180 kg ha<sup>-1</sup> urea treatment, which showed significant differences compared to the control and 180 kg ha<sup>-1</sup> urea+inhibitor treatments. Lower average emissions were measured in the urea+inhibitor treatments than in the non-inhibitor urea treatments applied at similar doses.

**COMPARING METHODS OF QUANTIFYING PLANT AVAILABLE N FOR SUSTAINABLE SYNTHETIC N FERTILISER PRACTISES TO REDUCE NO<sub>3</sub> LEACHING, NH<sub>3</sub> AND N<sub>2</sub>O EMISSIONS IN BABYLEAF SPINACH PRODUCTION SYSTEMS.**

E. BARBROOK, L. SHAW, T. SIZMUR

University of Reading- Department of geography and Environmental Science, Reading, UNITED KINGDOM

Extensive work has already been conducted on optimal N cycle inhibitors (NCI) and synthetic N fertiliser use in cereal systems. However, the short growth cycle (4-6 weeks) and multiple within-season harvests for babyleaf spinach, has implications for dynamics of soil N availability, potentially revealing novel relationships between indices of plant- available N. This work aims to apply strategies for minimising N loss from soil in cereal systems to babyleaf spinach crops for sustainable production.

1 mol KCl extraction and subsequent analysis of soil NH<sub>3</sub>-N and NO<sub>3</sub>-N is the industry standard for fertiliser rate recommendation. The inability of this method to estimate potentially available N (which becomes available via mineralization over time) limits this method. Consequently, we aimed to evaluate the ability of chemical, physical and biological methods to predict actual N supply of 15 UK soils (varied past fertiliser regimes (CAN, Nitram, FYM, spent mushroom compost)) whilst growing spinach over four weeks. This work aims to improve the way that fertiliser rates are recommended, to reduce N loss from soils whilst retaining yields.

Taking the best of these methods forward, they were used in field trials to quantify the amount of plant available N before fertilization. The trials were established to examine the interactive effects of N fertiliser application rate and nitrification inhibitor (NI) (nitrapyrin). NCIs are an effective solution to reducing NO<sub>3</sub> leaching and gaseous emissions from soil, without reducing crop yields. The objective of this trial is to determine whether a reduction in N fertiliser application can be achieved without losing marketable yield, whilst quantifying the efficacy of NIs as a tool for reducing N losses from soil.

Together this new approach to synthetic N fertiliser inputs for babyleaf spinach has allowed a 27- 37% reduction in fertiliser application rates whilst maintaining the same yields. Future research will introduce high carbon organic amendments (straw and spent cooking oil) to act as a low cost alternative to NCIs.

## 4. Soil health in achieving the Sustainable Development Goals 4.16 133568 - Managing soil carbon and nitrogen for climate-smart and sustainable agriculture

### LONG-TERM RESILIENCE OF SOIL ORGANIC CARBON STOCKS TO CLIMATE CHANGE THROUGH TILLAGE AND RESIDUE MANAGEMENT

V. STEPONAVICIENE, V. BOGUZAS, G. ZIURAITIS

Vytautas Magnus University Agriculture Academy, Kaunas, LITHUANIA

The innovative approach to sustainable farming has been developed on the basis of research carried out and it is the significant impact of soil health on agricultural productivity. The long-term stationary field experiment was established at Vytautas Magnus University Experimental Station at 54°52'50" N latitude and 23°49'41" E longitude on Plansoils in 1999.

The aim this study was initiated to evaluate the effects of long-term reduced tillage and no-tillage in combination with the use of plant residues and cover crops for green manure on soil organic carbon (SOC) and CO<sub>2</sub> emissions. Soil tillage systems and other complex measures in permanent crop rotation influenced the accumulation of SOC. In plots without straw reduced tillage systems SD, NTCC and NT increased SOC poll in the 0-25 cm soil layer by 23.1-29.1 % compared with that in conventional tillage. Straw retention in these treatments increased SOC poll by 19.5-31.0 %. Reduced tillage systems SD, NTCC and NT intensified the accumulation of SOC and humification was observed.

Different farming methods have been analysed, with a particular focus on the effects of straw management and different tillage systems, including deep and shallow ploughing, as well as no-till farming. Straw removal or chopping combined with other tillage systems has been observed to lead to significant increases in soil organic carbon. This increase not only contributes to reducing CO<sub>2</sub> emissions but also increases soil resilience. As a result, better crop growth and yields have been consistently observed. It is recognized that the adoption of these practices is vital to maintaining healthy and productive soils, which is essential in the face of the growing challenges of climate change. The research underlines the importance of sustainable farming practices that priorities soil and environmental health

The research was financed by EJP SOIL program SOMPACS/2022.

The reduction of fertilizer input is a major need in agricultural practices to achieve a sustainable food production chain and to improve the soil health. The Nitrates EU Directive brings the focus on nitrogen supply in agriculture and the importance of its careful use. In this regard, the organic farming provides an environmental-friendly approach of circular economy for horticultural production. Nevertheless, the optimization of nitrogen supply is still crucial to avoid its leaching.

In line with this need, the main goal of the MOMA project (granted by PSR 2014-2020 – Mis. 16.2, Tuscany Region, Italy) is the development of a sustainable strategy for chili pepper production, assuring an optimal nitrogen supply to meet the producer expectations and the soil quality preservation. The experiment was carried out at Azienda Agricola Marco Carmazzi (Italy), one of the main chili pepper producers in Europe, in an open-field cultivation with several cultivars of *Capsicum* spp.. During the first year of monitoring (spring-autumn 2023), after the soil application of manure and green compost, plants were fertigated with fluid vinasse. The physical and chemical soil properties, including nitrogen content, were monitored alongside the soil enzyme activities and stoichiometry, determined as an indicator of nutrient cycling. In parallel, plant health status using both nondestructive (i.e., optical proximal and remote sensors) and destructive (i.e., lab quantification) measurements was assessed. In this work, the data obtained during the first year of experiment are presented and their implication will drive the strategy for the second year of activities. The MOMA project will provide guidelines for farmers, promoting a sustainable and soil-friendly use of nitrogen fertilization.

### DIFFERENTIAL EFFECTS OF CELLULOSE AND STARCH ON POST-HARVEST SOIL N RETENTION: AN INCUBATION STUDY WITH FOUR DIFFERENT SOILS

K. ZHAO, R. REICHEL, N. BRÜGGEMANN

Forschungszentrum Jülich GmbH, Jülich, GERMANY

Post-harvest mineralization cause mineral nitrogen (N) accumulation in the soil after harvest, leading to the high N losses both in the form of nitrate to groundwater and nitrous oxide (N<sub>2</sub>O). High-carbon amendments (HCA), such as cellulose and starch, have shown great potential to immobilize excess mineral N by stimulating microbial biomass growth and activity at ambient temperatures and in specific soils. However, it is not clear yet whether the N immobilization of these HCAs can be harnessed under realistic climatic conditions and in different soils. To elucidate the effect of cellulose and starch on N immobilization during the post-harvest period, we conducted a 98-day laboratory incubation experiment with four different agricultural soils. A typical post-harvest scenario was created by adding ammonium equivalent to 50 kg NH<sub>4</sub><sup>+</sup>-N ha<sup>-1</sup> to the soil prior to application of the HCAs, which were then applied at a rate equivalent to 4 t C ha<sup>-1</sup>. Five different treatments were implemented for each agricultural soil: without nitrogen and HCA application (Blank), application of NH<sub>4</sub><sup>+</sup>-N, but no HCA (Control), and then NH<sub>4</sub><sup>+</sup>-N applied with cellulose (Cellulose), starch (Starch), or a combination of cellulose (2 t C ha<sup>-1</sup>) and starch (2 t C ha<sup>-1</sup>) (Cellulose+Starch), respectively. After 98 days of incubation, all HCA treatments had significantly lower nitrate levels in all four soils compared to Blank and Control. The faster decomposition of starch in the early stages of incubation led to a faster reduction in nitrate content than in the Cellulose and Cellulose+Starch treatments, but also to faster remineralization in the later incubation stages, leading to an increase again in mineral N in the Starch treatment. In contrast, the decomposition rate of cellulose was lower, but there was also no significant increase in mineral N after 98 days of incubation. This suggests that cellulose is more suitable than starch for long-lasting stimulation of microbial N immobilization under post-harvest conditions in the four different soils.

### METHANE AND NITROUS OXIDE EMISSIONS FROM RICE PADDY WITH DIFFERENT SOIL MANAGEMENT

G.H. LEE

Pusan National University, Miryang, SOUTH KOREA

The objectives of this study were to evaluate emissions of methane (CH<sub>4</sub>) and nitrous oxide (N<sub>2</sub>O) from rice paddy with different soil management during the growing season and determine optimum soil management for mitigation of CH<sub>4</sub> and N<sub>2</sub>O emissions. Four treatments including conventional (NPK), compost manure (CM), combination of NPK and CM (NPK+CM), and the control (C) were installed on a paddy soil. The rice (*Oryza sativa* L.) was transplanted on June 9th 2023. Gas samples for CH<sub>4</sub> and N<sub>2</sub>O were collected from June 10th 2023 to September 26th 2023 date twice in every week. The daily CH<sub>4</sub> fluxes increased during the submerged period but decreased during the mid-season drainage. The order of cumulative CH<sub>4</sub> emissions from the greatest to the least was NPK+CM>NPK>CM>C. The greater cumulative CH<sub>4</sub> emissions in NPK compared to CM might be due to different growth characteristics of rice plant between both treatments. Daily N<sub>2</sub>O fluxes were variable during the submerged period but dramatically increased in all treatments during the mid-season drainage. The order of cumulative N<sub>2</sub>O emissions from the greatest to the least was NPK+CM>NPK>CM>C. The cumulative N<sub>2</sub>O emissions in NPK was greater compared to CM, because more inorganic nitrogen which was a source of N<sub>2</sub>O production was supplied with NPK. Among three soil managements including CM, NPK, and CM+NPK, the least CH<sub>4</sub> and N<sub>2</sub>O emissions were observed in CM in this study. Further research on soil management for mitigation of both CH<sub>4</sub> and N<sub>2</sub>O emissions should be conducted for long-term experiment.

### LONG-TERM LIMING MITIGATES THE POSITIVE RESPONSES OF SOIL CARBON MINERALIZATION TO WARMING AND LABILE CARBON INPUT

Q. XIAO <sup>1</sup>, W. ZHANG <sup>1</sup>, L. WU <sup>1</sup>, Y. HUANG <sup>1</sup>, J. WANG <sup>1</sup>, X. XU <sup>2</sup>, I. P. HARTELY <sup>3</sup>

<sup>1</sup> Chinese Academy of Agricultural Sciences (CAAS), Beijing, CHINA

<sup>2</sup> Chinese Academy of Sciences (CAS), Beijing, CHINA

<sup>3</sup> University of Exeter, Exeter, UNITED KINGDOM

Liming, as a common soil amelioration practice worldwide, has the potential to alleviate acidification and enhance soil productivity. However, the impacts of liming on the temperature sensitivity (Q<sub>10</sub>) of soil organic carbon (SOC) mineralization and its response to labile C input remain unclear. To fill the knowledge gap, soil samples were collected from a long-term (10 years) field trial with unlimed and limed treatments. These soil samples were incubated at 15 and 25 °C for 42 days, amended with or without <sup>13</sup>C-labeled glucose. Results demonstrated that liming increased SOC mineralization by 25-58%, but decreasing its response to warming, resulting in lower Q<sub>10</sub>, as compared to the unlimed soil. Long-term liming increased bacterial richness and Shannon diversity as well as their response to warming which were associated with reductions in Q<sub>10</sub>. Furthermore, the decreased Q<sub>10</sub> due to liming was strongly associated with the decreased response of bacterial oligotrophs/copiotrophs ratio, b-glucosidase and xylosidase activities to temperature. These results indicated the importance of microbes play a pivotal role in regulating SOC mineralization in response to liming and temperature. Labile C addition had a strong impact on Q<sub>10</sub> in the unlimed soil, but only marginal significance in the limed soil. Overall, these findings provide compelling evidence that liming has the potential to mitigate the positive response of SOC mineralization to warming and labile C input, thereby facilitating SOC sequestration in agroecosystems, particularly under global climate change scenarios.

**LONG-TERM FERTILIZER POSTPONING PROMOTES SOIL ORGANIC CARBON SEQUESTRATION IN PADDY SOILS BY ACCELERATING LIGNIN DEGRADATION AND INCREASING MICROBIAL NECROMASS**

G. LI

Nanjing Agricultural University, Nanjing, CHINA

Soil organic matter (SOM) in paddy soils is critical for achieving high crop yield sustainability and mitigating climate change. Our previous study revealed that long-term fertilizer postponing (FP) increases yield by improving SOM. Therefore, in this study, the mechanism by which fertilizer postponing increase SOM were investigated through a long-term experiment (11 years). Long-term FP significantly increased SOM (by 14.5%) by increasing root residue input. FP increased soil phenol oxidation and peroxidase activity but did not affect glucosidase activity, indicating that FP accelerated lignin degradation rather than cellulose degradation. Metagenome analysis also showed that FP significantly increased the relative abundance of lignin degradation genes, such as soil catalase, cytochrome c peroxidase, and peroxidase genes, by activating the growth of related microorganisms. In addition, long-term FP significantly increased bacterial necromass C (by 17%) and fungal necromass C (by 13%) by improving microbial biomass. Redundancy analysis and random forest model further revealed that lignin degradation genes (representing the contribution of lignin) and bacterial necromass C were dominant in plant- and microbe-derived C, respectively. We confirmed that the soil  $\text{NH}_4^+\text{-N}$  content was the main driving factor for high lignin degradation and microbial necromass variation. Structural equation model and random forest model revealed that soil carbon sequestration was mainly through the increase of lignin degradation and microbial necromass under high root residues input and soil  $\text{NH}_4^+\text{-N}$  content. Overall, our findings suggest that long-term FP is a sustainable agricultural management strategy that improves SOM by accelerating lignin degradation and increasing microbial necromass.

### MICROBIAL MECHANISMS OF LONG-TERM FERTILIZER POSTPONING FOR PROMOTING SOIL ORGANIC CARBON SEQUESTRATION IN PADDY SOILS

G. LI

Nanjing Agricultural University, Nanjing, CHINA

Soil organic carbon (SOC) sequestration in paddy soils is crucial for achieving high crop yields and mitigating climate change. Long-term fertilizer postponing (FP) has been shown to be an effective agricultural management to improve grain yield potential and soil fertility. However, the mechanism of FP improving soil fertility is still unclear. Therefore, in this study, we used metagenomics sequencing and <sup>13</sup>C-phospholipid-derived fatty acid (<sup>13</sup>C-PLFA) to elucidate the microbial mechanism of FP for SOC sequestration from the perspective of both plant residual C and living root-released C. According to plant residual C, FP significantly increased soil organic matter (SOM) content by 14.5%, mainly by increasing root biomass and affecting the conversion of root residues to SOM. FP increased the relative abundance of lignin-degrading genes by activating the growth of associated microorganisms, thereby increasing lignin-degrading enzyme activities. In addition, FP significantly increased bacterial necromass C (by 17%) and fungal necromass C (by 13%) by elevating soil ammonium nitrogen (NH<sub>4</sub><sup>+</sup>-N) content. According to living root-released C, FP did not affect the ability of plants to assimilate photosynthetic C in the rice panicle initiation stage (PI) and heading stage (HS), but significantly reduced the loss of photosynthetic C in PI. Photosynthetic C loss was significantly and positively correlated with the microbial biomass and community. FP significantly reduced the total <sup>13</sup>C-PLFA content in the panicle initiation stage, where the dominant microorganisms were bacteria. However, FP significantly increased the total <sup>13</sup>C-PLFA content in HS, where the dominant microorganisms were fungi. Therefore, long-term fertilizer postponing enhances SOC sequestration by altering the microbial community structure to reduce the loss of root-released C and accelerating lignin degradation to increase microbial necromass C content.

## 4. Soil health in achieving the Sustainable Development Goals 4.16 133568 - Managing soil carbon and nitrogen for climate-smart and sustainable agriculture

**THE EFFECT OF SOIL MICROBIAL RESIDUES-MEDIATED NITROGEN CONSERVATION AND SUPPLY DURING THE GROWING SEASON ON NITROGEN UPTAKE BY WHEAT**

Y. ZHANG

Center for Agricultural Resources Research, Institute of Genetic and Developmental Biology, Chinese Academy of Sciences, SHIJIAZHUANG, CHINA

Microbial residue nitrogen can indicate soil quality and is crucial for soil nitrogen retention and supply. However, it is still unclear how the dynamic changes in soil microbial residue nitrogen affect crop nitrogen uptake in agricultural practice. Based on a long-term wheat-maize rotation experiment with different nitrogen application rates (150 kg N/ha, 200 kg N/ha, and 300 kg N/ha), <sup>15</sup>N-labeled nitrogen fertilizer was applied during the wheat season to track the dynamics of soil microbial residue nitrogen and its mediated fertilizer nitrogen. The results showed that nitrogen addition was beneficial to the accumulation of microbial residue nitrogen (mainly fungal microbial residue nitrogen). Its contribution rate to soil total nitrogen is 54.87–56.55%, and the fertilizer nitrogen allocated to it accounts for 27.10–47.50% of the remaining fertilizer nitrogen in the soil. Ultimately, 6.77–10.24% of the nitrogen fertilizer applied remained in the soil as microbial residue nitrogen. In addition, microbial residue nitrogen is mainly mineralized during the jointing and filling stages of wheat. In a word, the accumulation and mineralization of soil microbial residue nitrogen during the application of 200 kg N/ha better guaranteed the uptake of nitrogen by wheat, which provided a reliable basis for guiding farmland fertility improvement and nitrogen fertilizer reduction in the North China Plain.

### PADDY SOIL NITROGEN DYNAMICS DRIVE NITROGEN USE EFFICIENCY VARIATION BETWEEN YANGTZE RIVER BASIN AND NORTHEAST CHINA

X. ZHAO, S. CAI, Y. LIU, X. YAN

Institute of Soil Science, Chinese Academy of Sciences, Nanjing, CHINA

Yangtze River Basin and Northeast China account for 36% of the Chinese rice cultivation area, yet considerable spatial disparities in nitrogen use efficiency (NUE) existed between these regions. This study interrogates the soil nitrogen (N) dynamics underlying these regional NUE variations, a subject hitherto underexplored. By a case study in two sites and later a region scale samples, we determined the discrepancies in soil N flows and its driving factors between Yangtze River Basin and Northeast China. Initial field studies at Wuchang (Northeast China) and Changshu (Yangtze River Basin) indicated Wuchang's superior NUE alongside reduced ammonia volatilization. Subsequent soil replacement pot-scale experiments further demonstrated that both apparent and  $^{15}\text{N}$ -traced NUE were higher, whereas  $^{15}\text{N}$  fertilizer losses were lower in Wuchang-soil irrespective of site, suggesting soil types contribute to differences in soil N retention capacity and cause NUE discrepancies between two sites. Moreover, process-scale results revealed Changshu's amplified reactive N losses-attributable to significantly elevated rates of gross N mineralization, nitrification, and denitrification. It suggested that the N mineralization dynamics, possibly driven by inherent soil properties, contributed significantly to the observed NUE discrepancies. Expanding to a regional scope with 36 and 24 paddy soil samples from the Yangtze River Basin and Northeast China, respectively, reinforced these site-specific observations, with the former displaying enhanced long-term N mineralization potential, highlighting the pivotal role of soil N mineralization in determining regional NUE disparities. Correlations between soil properties—such as total N, pH, C/N ratio, and clay content—and N mineralization characteristics further elucidated the inherent factors of differentiated regional N dynamics. This comprehensive analysis not only elucidates the soil-mediated factors influencing NUE disparities, but also advances the development of region-specific, rapid N mineralization prediction models, contributing significantly to climate-smart and sustainable agricultural practices.

### IRON FERTILIZATION AND SOIL CARBON SEQUESTRATION IN RICE PADDIES

S.J. GALGO<sup>1</sup>, P.J. KIM<sup>1,2</sup>

<sup>1</sup> Institute of Agriculture and Life Sciences, Gyeongsang National University, JINJU, SOUTH KOREA

<sup>2</sup> Division of Applied Life Science (BK21+ Program), Gyeongsang National University, JINJU, SOUTH KOREA

Iron (Fe) fertilization of the ocean mitigates global warming by sequestering carbon dioxide (CO<sub>2</sub>) in phytoplankton, but the effect of Fe fertilization on carbon (C) sequestration in arable soils remains unknown. Iron is often added to rice paddies as blast furnace slag (BFS), a byproduct of steel manufacturing used as a silicate fertilizer to improve productivity. However, BFS also contains large amounts of Fe oxides, which might promote C sequestration by forming complexes with organic matter. First, to estimate the effect of continuous Fe addition via BFS on soil organic C (SOC) stock, soils were nationally sampled in South Korea. A strong positive correlation between SOC and extractable Fe and available Si concentrations was found, which might presume that the periodic BFS application contributed to an increase in SOC stock. Second, to confirm the effect of Fe addition on SOC stock increase, the effect of BFSs, which have different mixing rates of Fe oxides (0-5%, wt wt<sup>-1</sup>) on the respired C loss was investigated via incubation test. Finally, to verify the effect of Fe addition on SOC stock changes, three different Fe-enhanced silicate fertilizers were applied for rice cultivation, and SOC stock changes were estimated using the net ecosystem C budget. Silicate fertilization significantly increased net primary production (NPP) by 18-20% over the control, and this NPP was more highly increased with increasing Fe addition. Silicate fertilizer application highly decreased the respired C loss by 15-30% over the control. As a result, silicate fertilizer application increased around 0.67 Mg C ha<sup>-1</sup> of SOC stock over the control during rice cultivation, but this C stock was more highly increased with increasing Fe addition. In conclusion, Fe-enhanced silicate fertilizer might be more effective in improving SOC stock and crop productivity in rice paddies.

**Keywords:** silicate fertilizer, net ecosystem carbon budget, net primary production, soil respiration

### THE EFFECT OF INCORPORATION, SURFACE APPLICATION AND INHIBITOR USAGE ON AMMONIA EMISSIONS APPLYING UREA FERTILIZER ON SANDY SOIL

E. TOTH, M. DENCISO, K. POKOVAI, M. MAGYAR

Institute for Soil Sciences, HUN-REN Centre for Agricultural Research, Budapest, HUNGARY

In 2016, the EU adopted the National Emissions reduction Commitments Directive (NEC Directive), which includes emission reduction obligations for ammonia (NH<sub>3</sub>) for all European country. As agriculture is responsible for 95% of NH<sub>3</sub> emissions, this target cannot be achieved without more efficient use of fertilizers and accurate measurement and assessment of the impact of different factors on NH<sub>3</sub> emissions.

We set up two experiments, where we investigated the NH<sub>3</sub> emission after using urea as fertilizer at two different doses (150 and 180 kg ha<sup>-1</sup> Nitrogen active ingredient). In a laboratory experiment we examined the effect of incorporation, surface application and usage of inhibitor, and in a filed pot experiment the effect of inhibitor usage was studied. For both experiment, sandy soil was used (humus content: 0.78 and 0.79 % at 0-20 and 20-40 cm depth, respectively).

In the laboratory experiment NH<sub>3</sub> emissions (after surface application, without inhibitor) reached a maximum in four days and then started to decrease. In contrast, when the inhibitor-treated fertilizer was applied, the peak was slightly delayed, occurring only on the sixth day. The usage of inhibitor reduced most effectively soil NH<sub>3</sub> emissions, with the magnitude of emissions in these treatments being comparable to the control treatment (where no urea applied). In the case of the surface application of non-inhibitor-treated urea, even a 30 kg ha<sup>-1</sup> increase in active ingredient resulted in a significantly detectable difference in soil NH<sub>3</sub> emissions.

In the field pot experiment, we found that after application of urea fertilizer, NH<sub>3</sub> emission increased significantly compared to the pre-fertilization condition, and this increased NH<sub>3</sub> emission lasted for about two weeks.

In the first week, the average NH<sub>3</sub> emission was highest in the 180 kg ha<sup>-1</sup> urea treatment, which showed significant differences compared to the control and 180 kg ha<sup>-1</sup> urea+inhibitor treatments. Lower average emissions were measured in the urea+inhibitor treatments than in the non-inhibitor urea treatments applied at similar doses.

Numerous studies have reported that straw return before rice transplanting stimulates substantial CH<sub>4</sub> emissions. It is urgent to explore novel modes of returning straw and corresponding field management to mitigate CH<sub>4</sub> emissions without compromising yield. We conducted a 2-year field experiment, including two wheat straw returning modes [conventional straw evenly-plowed returning (SR), and straw centralized returning (SCR)], to evaluate greenhouse gas (GHG) emissions, crop yields, carbon footprint (CF), and net ecosystem economic benefit (NEEB) in the rice-wheat rotation system. The results showed that the GHG emissions contributed the most to annual CF, accounting for 59% and 62% in SR and SCR, respectively. Mean CF in SCR was 7.0 t CO<sub>2</sub>-eq ha<sup>-1</sup> yr<sup>-1</sup>, with 14% lower than that in SR, which was attributed to the significantly lower annual CH<sub>4</sub> (by 19%) during the rice seasons. The lower soil water contents might partly regulate the CH<sub>4</sub> emissions by decreasing DOC contents (12–14%) and increasing the soil Eh, which resulted in a lower CH<sub>4</sub> production (45–46%) and production/oxidation ratio in SCR. Annually, the total yields of rice and wheat were 9.53 t ha<sup>-1</sup> and 9.38 t ha<sup>-1</sup> in SR and SCR, respectively, indicating the comparable yield gains between them. Nevertheless, the relatively lower agricultural input costs and carbon footprint costs in SCR, thus leaving the NEEB increased by 83 CNY ha<sup>-1</sup> relative to SR. The findings indicate that straw centralized returning under rainfed conditions in the rice season could reduce both CH<sub>4</sub> emissions and carbon footprint while sustaining food security and economic benefit in the rice-wheat rotation system.

**Keywords:** GHG emissions, straw returning, crop yields, net ecosystem economic benefit, carbon footprint

<sup>5</sup> Institute of Agriculture and Life Sciences, Gyeongsang National University, Jinju, SOUTH KOREA

Climate change has the potential to impact soil organic carbon (SOC) stock in rice paddy, as elevated air temperature and atmospheric carbon dioxide concentration ([CO<sub>2</sub>]) can alter both major carbon (C) input (i.e. net primary production, NPP) and output (i.e. heterotrophic respiration). However, most climate change experiments investigated the response of either biomass productivity or C decomposition rate. We used two types of open-top chambers representing present conditions (+0°C, +0 ppm) and projected climate change conditions (+2°C, +200ppm) to investigate the net effect of climate change on SOC stock in rice paddy. Additional chambers with elevated temperature (+2°C, +0 ppm) were installed to isolate the individual effects of temperature and [CO<sub>2</sub>]. Changes in SOC stock were assessed using net ecosystem C balance (NECB) analysis, where the balance between C input and output indicates SOC stock changes. Compared to the present conditions, climate change did not change grain yield due to trade-off between the contrasting effects of elevated temperature and [CO<sub>2</sub>] on grain yield components. NPP during the fallow season significantly decreased, as the impact of increased temperature outweighed that of elevated [CO<sub>2</sub>]. However, during the cropping season, rice NPP remained unchanged. The climatic change conditions significantly stimulated SOC mineralization by 157-429% over the present conditions, particularly as CO<sub>2</sub> during the fallow season, due to pronounced stimulating effect of warmer temperature. Consequently, the climate change conditions led to a substantial decrease (119-271%) in NECB values compared to the present conditions, due to the dominant effect of warmer temperatures. Our findings demonstrate that rice paddies represent positive feedback on climate change, because accelerated C release from warmed soils will override C gains from NPP. Therefore, to reduce the expected SOC depletion in rice paddy under changing climate, conservation soil management practices during cold and dry fallow season should be implemented.

### IMPROVING NITROGEN RECOMMENDATIONS TO PROMOTE PROFITABILITY, GRAIN QUALITY, AND NITROGEN USE EFFICIENCY IN TWO-ROW MALTING BARLEY

B. GOETTL<sup>1</sup>, T. DESUTTER<sup>1</sup>, H. BU<sup>1</sup>, A. WICK<sup>2</sup>, D. FRANZEN<sup>1</sup>

<sup>1</sup> North Dakota State University - School of Natural Resource Sciences, Fargo, USA

<sup>2</sup> Syngenta Group - Global Soil Health Academy, Fargo, USA

As the demand and cultivation of two-row malting barley (*Hordeum vulgare* L.) increases in the Northern Great Plains of the United States, updated N recommendations are increasingly necessary. Not only does N play a role in grain yield, but it also impacts grain malting characteristics including protein and kernel plump. Historically, nitrogen fertilizers were applied with the goal of optimizing yield; however, as the point of maximum yield is reached, nitrogen efficiency per unit of grain decreases. To combat this barley nutrient recommendations were developed to maximize profitability by ensuring nutrients, especially nitrogen, are applied at rates which maximize use efficiency and grain quality, thereby reducing unnecessary over application. Two experimental sites were established in eastern North Dakota during the both the 2020 and 2021 growing seasons. Treatments consisted of five fertilizer rates from 0 to 180 kg N ha<sup>-1</sup> and two malting barley cultivars. Soil samples to be analyzed for NO<sub>3</sub>-N were taken prior to planting and N credit estimates from the previous crop were considered to determine the total known available N (TKAN) in the soil. It was determined there was a strong relationship between N rate and grain yield along with a strong positive correlation between N rate and grain protein. No significant interactions between N rate and kernel plump were noted. When the relationship between relative grain yield and TKAN was modeled using a best-fit regression, it was determined maximum yield was attained at 210 kg TKAN ha<sup>-1</sup> with a grain protein of 128 g kg<sup>-1</sup>, meeting malting quality requirements. When factoring in grain value and cost of urea fertilizer, the TKAN range needed to produce the crop at the highest profitability and N use efficiency was lower than TKAN of maximum yield, ranging from 89 to 190 kg TKAN ha<sup>-1</sup>.

### CEREAL-LEGUME INTERCROPPING FOR ENHANCING SOIL FERTILITY IN SUSTAINABLE AGRICULTURE

S. JAKSIC, J. NINKOV, S. MILIC, J. VASIN, D. BANJAC, M. ZIVANOV, D. ANDJELIC

Institute of Field and Vegetable Crops, the National Institute of the R. of Serbia, Novi Sad, SERBIA

The intercropping of legumes with cereals offers scope for developing energy-efficient and sustainable agriculture. Legume supported systems have a high potential for mitigating climate change through the reduction of fossil fuel use and GHG emissions, as well as increasing C sequestration. Long-term intercropping increases soil C sequestration compared to monoculture, with the changes in C storage ranging from -0.020 to 0.184 t C/ha/yr. Intercropping increases crop yields and it provides several ecological services such as pest, disease and weed control, soil biodiversity, and it has positive effects on nutrient use efficiency and soil quality.

The aim of this research was to examine the influence of intercropping on some soil properties. Two-year trials (2021-2023) were carried out on the experimental fields of the IFVCNS. Treatments: intercropping (winter wheat + forage pea)-I; winter wheat-WW; forage pea-FP; control-C. Soil samples were taken in autumn and in May.

The lowest K content was found in WW variant, 2.21 % and was significantly lower compared to FP (2.67 %). The content of K in I variant was 2.31 %. The P content was the highest in the FP (2.71 %), and the lowest in the WW variant (2.10 %). The content of P in the I variant was 2.31%. Total N content was the lowest in the WW (0.16 %) and in the C variant (0.17%). The results from the FP and I variant were 0.18 %.

The lowest SOC content was obtained in WW (12.7 g/kg) and then in the C variant (13.33 g/kg). The highest SOC content was in FP, 13.90 g/kg, and in the I variant, 13.83 g/kg. Although the SOC content was slightly higher, positive C balance cannot be found automatically, it takes many years. Long term results will be climate change mitigation and a significant contribution to climate neutrality through enhanced C sequestration. Intercropping as well as single legume crop are a good options for enhancing soil fertility.

### COMPARING CONVENTIONAL AND ORGANIC CROPPING SYSTEMS WITH PROCESS-BASED MODELLING AND FUZZY LOGIC IN FINLAND

R. CALONE<sup>1</sup>, E. VALKAMA<sup>2</sup>, M. ACUTIS<sup>3</sup>, M. BOTTA<sup>3</sup>, A. PEREGO<sup>3</sup>, C. DI BENE<sup>4</sup>, S. BREGAGLIO<sup>1</sup>

<sup>1</sup> CREA - Council for Agricultural Research and Economics, Research Centre for Agriculture and Environment, Bologna, ITALY

<sup>2</sup> Natural Resources Institute Finland (LUKE), Bioeconomy and environment, Turku, FINLAND

<sup>3</sup> Department of Agricultural and Environmental Sciences - Production, Landscape, Agroenergy, University of Milan, Milano, ITALY

<sup>4</sup> CREA - Council for Agricultural Research and Economics, Research Centre for Agriculture and Environment, Roma, ITALY

Reducing nitrate (NO<sub>3</sub>) leaching, nitrous oxide (N<sub>2</sub>O) emissions, and soil organic carbon (SOC) losses are prominent environmental challenges for European agriculture. Organic farming practices are expected to promote soil health and are expanded the share of cultivated lands in Europe, even though with inconsistent findings on the effects on soil biogeochemical properties, biodiversity, and N emissions. This study utilizes the process-based ARMOSA crop model to investigate the impact of alternative farming practices on SOC dynamics, NO<sub>3</sub> leaching, and N<sub>2</sub>O emissions in crop and livestock production farms for the current climate. The South Savo region of Finland was chosen as indicative of continental subarctic climates (Köppen-Geiger classification). Soil for simulation was loamy sand (sand 76%, clay 4%, silt 20%), or sandy texture and it was classified as Aquic Haplocryod (Finland Soil Taxonomy), with SOC of 3.5%, C/N ratio of 17, and pH of 6.2 (water) in 0-30 cm soil layer

Five-year crop rotations have been designed according to prevalent conventional and organic practices in the area. In the crop production farms, rotation included cereals (with fodder pea in the organic farm), oilseed rape and grass, while in the livestock farm, the rotations consisted of two years of cereals followed by a 3-year fescue and timothy meadow (with clover in the organic farm). Nine scenarios were simulated involving the different combinations of residue management strategies (retained/removed) and fertilization sources in the conventional systems (mineral fertilizers alone or with slurry integration) and in the organic systems (slurry/green manure/meat and bone meal-based commercial organic fertilizer).

Results from each scenario have been aggregated using a fuzzy logic-based composite index, the Sommit index, which assesses the trade-off between crop yield, N<sub>2</sub>O emissions, NO<sub>3</sub> leaching, and soil organic carbon stock on a scale from 0 (bad) to 1 (good). This index, adaptable to specific contexts, facilitates a sensitive evaluation of interdependent variations within the trade-off components during scenario transitions, offering insights crucial for informed agricultural decision-making

### THE ORCHID DUMP – A PARTICULAR SITE IN A HISTORICAL AS MINING AREA. SOILS AND VEGETATION

A. DRADRACH <sup>1</sup>, K. LEWINSKA <sup>2</sup>, A. KARZEWSKA <sup>3</sup>

<sup>1</sup> Wroclaw University of Environmental and Life Sciences, Institute of Agroecology and Plant Production, Wroclaw, POLAND

<sup>2</sup> Adam Mickiewicz University in Poznan, Department of Soil Science and Remote Sensing of Soils, Poznan, POLAND

<sup>3</sup> Wroclaw University of Environmental and Life Sciences, Institute of Soil Science, Plant Nutrition & Environ. Protection, Wroclaw, POLAND

In the Sudetes, there are numerous mineralization zones where ores were mined in the past. Historical mining produced waste dumps with high concentrations of toxic elements. One of such sites is Zloty Stok where gold and arsenic were mined over centuries. The largest (2.4 ha) mine dump in this area, called Orchid Dump, will be described. The dump is built of metamorphic rocks, mainly gneisses, schists, amphibolites, and crystalline limestone. They contain various As-rich minerals, such as arsenopyrite and loellingite, as well as different metal-bearing minerals. Soil parent material consists of weathered mine rocks, admixture of exogenous soil used for reclamation and humified plant residues.

Our research confirmed that soils and habitats on the dump are highly heterogeneous. Arsenic concentrations in 50 topsoil samples ranged 230-55,000 mg/kg (median 9800 mg/kg). Potentially soluble arsenic, extracted with 0.43 M HNO<sub>3</sub>, constituted 5.6-87% of total As, with a median 32%, and currently soluble As, extracted in 1 M NH<sub>4</sub>NO<sub>3</sub>, was below 8 mg/kg, making <0.001-5.5% of total As, with a median 0.012%. Sequential extraction according to Wenzel, indicated that As was mainly present in amorphous Fe oxides-bound and residual fractions. Each of them constituted 30-60% of total As, depending on weathering stage of As-bearing minerals. Despite high concentrations of toxic elements, the Orchid Dump is a unique and precious site in terms of nature, protected as ecological site. Its most important ecosystems are xerothermic calamine meadows (*Violetea calaminariae*) with several protected plant species, that form mosaics with scattered heathlands and other associations. The dump owes its name to large population of *Orchis mascula* L. Most plants growing on the dump, including grass, are capable of arsenic avoidance. Typical As concentrations in *Agrostis capillaris* shoots were in the range 1.8-15.4 mg/kg (median 5.4 mg/kg), although single individuals accumulated more As in their shoots (35.9-115 mg/kg). Various mechanisms of As avoidance are involved there, however a hypothesis on its genetically-determined character has not been confirmed.

### POSSIBLE CAUSES OF THE SUCCESS/FAILURE OF RIPARIAN FOREST RESTORATION PROJECTS AFTER THE BREAKDOWN OF THE FUNDÃO DAM (MARIANA/BRAZIL)

A.R. KOZOVITS, B.N. REGO, M.G. LEITE

Federal University of Ouro Preto, Ouro Preto, BRAZIL

Almost eight years after the collapse of the Fundão dam, which impacted the Doce river basin up to the Atlantic Ocean, results of restoration actions on areas impacted by tailings still need to be better understood. Although the actions developed by the Renova Foundation have resulted in satisfactory seedling mortality rates (general average of 45%), especially when considering the unprecedented physical, chemical, and biological conditions of tailing deposits, a general standard explanatory of this mortality does not exist. Given the complexity of factors that interfere with the establishment and growth of seedlings, which vary significantly in time and space, a multicriteria analysis (MCA) was tested as a tool for identifying explanatory patterns of mortality. The study addressed forest restoration activities carried out on 268 work units on 65 rural properties, located in the municipalities of Mariana and Barra Longa, where direct planting of native seedlings was carried out. The analysis of groupings of properties by typologies and region (Mariana -Upstream, Mariana-Downstream and Barra Longa) revealed that different initial parameters demonstrated a greater cause and effect relationship with the mortality rates of the seedlings. In Mariana-Upstream, factors such as high waste thickness and slope of the margins, inadequate planting time, low concentration of phosphorus and base saturation, fewer rainy days and high incidence of livestock seem to have a more relevant effect on seedling mortality. On the other hand, in Barra Longa (35Km downstream), the flatter terrain and river morphology, less porous soils, location and width of restored forest, greater precipitation volume (including heavy rains that resulted in flooding events), better explained the mortality. The results indicate that concerning large-scale ecosystem restoration studies, AMC must be carried out in a regionalized manner, reflecting environmental heterogeneity and variation in study parameters. These must be weighted according to the characteristics of each region, avoiding the dilution of their effects by considering the entire study area as homogeneous.

### TECHNOSOLS IN ARTIFICIAL WETLANDS IN MINING LANDSCAPES: EFFECT OF HYDROTHERMAL GEOLOGICAL MATERIALS

J. DIAZ <sup>1</sup>, Y. RIVERA-URIA <sup>1</sup>, E. LÓPEZ-MENDOZA <sup>2</sup>, S. SEDOV <sup>1</sup>, F. MARTIN-ROMERO <sup>1</sup>, E. SOLLEIRO-REBOLLEDO <sup>1</sup>, G. MARTÍNEZ-JARDINES <sup>1</sup>

<sup>1</sup> Universidad Nacional Autónoma de México, MEXICO, MEXICO

<sup>2</sup> Posgrado Ciencias de la Tierra UNAM, MEXICO, MEXICO

<sup>3</sup> MEXICO

In this study, three profiles were analyzed inside the tailing dam: the PA profile under waterlogging conditions, the PB profile under periodic conditions of wastewater saturation, and the PC profile without waterlogging conditions. And a natural profile of the soil around the Tailings dam.

The analyzes carried out were: micromorphological (thin sections observed under a petrographic microscope) to detect the development of soil structure and other pedofeatures; fertility properties (pH, organic matter, available phosphorus, exchangeable bases, cation exchange capacity, electrical conductivity); mineralogical by X-ray Diffraction; total chemical composition Ti, Ca, K, Fe, As, Pb, Zn, Cu and Mn.

Irrigation of tailings with wastewater promoted biological aggregation and porosity of the soil matrix introduced nutrients and improved the soil ecological quality of hydromorphic Technosols. Saturation with wastewater hinders the oxidation of primary sulfides in hydromorphic Technosols, thus preventing acidification and the mobilization of heavy metal contaminants. The abundant hydrothermal clay minerals of hydrothermal origin in Technosols have a beneficial effect on the development of pedogenetic properties and processes.

The main micromorphological characteristics of wetland Technosols are the development of a biogenic structure and voids associated with organic materials, mainly root tissues. Primary sulfides remain unaltered in the Technosols irrigated with wastewater, while incipient oxidation of sulfides was observed in the non-irrigated tailings. Kaolinite and illite are the main components of the clay mineralogy in all profiles; Additionally, chlorite and smectite are detected in Technosols.

The organic matter content in Technosols is low; However, we consider the potential to form clay organic compounds that can improve soil quality. Furthermore, Technosols have adequate properties for plant growth, except for conductivity. They were not irrigated with cationic sewage and available P.

<sup>3</sup> Graduate Studies in Natural Resources of the Cerrado, State University of Goiás, Anápolis, Goiás, Brazil, Anapolis, BRAZIL

Limestone is one of the main agricultural inputs used in the agriculture of tropical regions. It has the power to neutralize acidity, which is the main inhibiting characteristic of oxisols, and it is also a source of nutrients such as Calcium and Magnesium. As it is a rock powder, its mining produces a residue that has chemical characteristics similar to those found in limestone, which can be classified as a by-product with high potential for agronomic use. Therefore, this study aims to evaluate the potential of using the by-product of limestone mining in improving the chemical attributes of the soil. The treatments consisted of 4 increasing doses of by-product equivalent to 0.8, 1.1, 1.45, and 1.8 Mg/ha, with ten repetitions, in a completely randomized experimental design, arranged in two factors, crushed and uncrushed residue. The application of limestone mining residue proved to be efficient in improving soil chemical attributes. When evaluating the influence of the application on the levels of Calcium, Magnesium, and Base Saturation, the treatment with 1.8 Mg ha<sup>-1</sup> uncrushed showed higher values than the other treatments. The control treatment had the worst indices, and the other treatments were statistically equal and positioned above the control treatment and below the treatment with 1.8 Mg kg/ha uncrushed. The limestone mining residue showed potential for the improvement of soil chemical attributes and can be used as a soil conditioner.

### DEVELOPMENT A DIRECT HG QUANTIFICATION METHOD BY THERMAL DECOMPOSITION, AMALGAMATION, AND ATOMIC ABSORPTION SPECTROPHOTOMETRY IN ABANDONED TAIL DAMS OF MINING OPERATIONS IN THE ATACAMA REGION, CHILE

F. CERECEDA-BALIC <sup>1</sup>, G. PUEBLA <sup>2</sup>, F. SANDOVAL <sup>2</sup>, S. FADIC <sup>2</sup>, X. FADIC <sup>2</sup>

<sup>1</sup> Centre for Environmental Technologies (CETAM) and Department of Chemistry, Universidad Técnica Federico Santa María, VALPARAISO, CHILE

<sup>2</sup> Centre for Environmental Technologies (CETAM), Universidad Técnica Federico Santa María, VALPARAISO, CHILE

As a result of the gold extractive activities carried out in the Atacama region, large quantities of Hg were accumulated in tail dams, generating a negative impact in the human health and ecosystems.

In order to quantify the total Hg present in soil samples, is necessary to create a new analytical method adapted to high Hg concentration.

This study has been promoted by the regional government of Atacama, framed in the Minamata Convention on Mercury, 2013.

For the determination of total Hg, a Milestone DMA-80 direct analyzer was used. This equipment combines thermal decomposition, amalgamation, and atomic absorption spectrophotometry.

The instrumental analytical method is adjusted with the official methods established in EPA 7473, ASTM D-6722-01 and D-7623-10. Our results provide satisfactory values of linearity ( $r^2 > 0,99$ ) sensitivity (between 0,0492 and 0,0007 ng), precision (0,52% RSD for repeatability and 0,47% RSD for reproducibility), accuracy (recovery of  $99,4 \pm 8,4\%$ ), while the LOD is 0,0015 ug/Kg and LOQ is 0.0030 ug/Kg.

The selected tailings dams are located in the Atacama region: Inca de Oro 1 and 2 ( $26^{\circ}45'S-69^{\circ}54'W$ ) both located in Chañaral, Pabellón ( $27^{\circ}39'S-70^{\circ}14'W$ ) and Totoralillo ( $27^{\circ}36'S-70^{\circ}14'W$ ) located in Tierra Amarilla, Bruzzone and Briceño, ( $28^{\circ}27'S-71^{\circ}10'W$ ) both located in Huasco.

Samples were taken from the surface of the tailings (0-5 cm) and at depth (50 cm), and mechanically processed to homogenize particle size and disaggregate it before analysis.

Given the high concentration of Hg in samples, it was diluted using Al<sub>2</sub>O<sub>3</sub> and then suspended in MilliQ water (by mechanical agitation, 300 seconds, 900 RPM). Aliquots of 300μL of this suspension were taken in triplicate for Hg quantification.

Thus, the total Hg contents in the suspension were obtained, subsequently recalculating the Hg concentration in the tailings, finding concentrations ranging from 0,94 mg/kg (Briceño Tailings) to 876 mg/kg (Pabellón Tailings) compared to the accepted maximum concentration in industrial soils of 43 mg/kg (U.S Superfund Contamination Site Program).

## 4. Soil health in achieving the Sustainable Development Goals 4.18 133571 - Contaminants of Emerging Concerns in Soil: Occurrence, Fate and Transport, Toxicity and Remediation

### CONTROLLABLE PREPARATION AND APPLICATION OF NANOMETER FE-CARBON FUNCTIONAL MATERIALS IN SOIL REMEDIATION

J. QU<sup>1</sup>, Y. ZHANG<sup>2</sup>

<sup>1</sup> Northeast Agricultural University, Harbin, CHINA

<sup>2</sup> Northeast Agricultural University, Harbin, CHINA

The nZVI-based remediation technology is limited by the dense oxide shell, which hinders electron transfer and requires a feasible solution. Specifically, nZVI is a promising persulfate (PS) activator whose dense oxide shell inhibits electron transfer to PS. Therefore, we introduced sulfurized and phosphorus-doped biochar to break up the original oxide shell and formed a mixed shell containing FeS and FePO<sub>4</sub>. We found that Fe core had a faster diffusion rate relative to the shell, triggering multiple Kirkendall effect that caused the vacancies to flow inward and merge into radial "lemon-slice-like" nanocracks. The crack facilitated the rapid outward transfer of electrons and Fe<sup>2+</sup> through the mixed shell to activate PS, resulting in effective dechlorination (90.6%) and mineralization (85.4%) of TCE. At the same time, SnZVI@PBC gradually lacked electrons, and then extracted electrons from TCE to achieve non-free radical degradation. This study provided a mechanism understanding for the formation and application of nanocracks induced by multiple Kirkendall effect on nZVI. Moreover, PnZVI@PBC was prepared using phosphate and phosphorus-doped biochar to cooperatively amplify the Kirkendall effect between FeO and the shell, and the Kirkendall effect between FeO and Cr(VI) was further amplified through the nanocracks, thus changing the adsorption configuration and shortening the electron transport channel. Based on this, the nZVI surface and internal electrodisplacement reactions were accelerated to achieve almost complete Cr(VI) reduction (97.0%). Surprisingly, we observed a distinct hollow core structure enriched with Cr(III), indicating that PnZVI@PBC synchronized the immobilization, detoxification, and oxidation resistance of Cr(VI) for sustainable repair. In summary, the Kirkendall strategy based on non-metallic elements and the advanced mechanism of enhancing the electric displacement reaction on nZVI provided the possibility for a wide range of repair applications.

<sup>2</sup> METIS - Sorbonne Université, Paris, FRANCE

<sup>3</sup> ISTeP - Sorbonne Université, Paris, FRANCE

Trace elements are chemical elements found in low concentration in the environment, including: (1) essential elements for plants and/or animals (such as Cu, Zn, and Mn), which can frequently cause human deficiency (common for Mo and Se) and toxicity when concentrations are below or above certain thresholds, respectively; and (2) elements without identified biological role that only pose a human health risk when concentrations are above a certain threshold value (such as As, Cd, and Pb). Transfer of these elements from soils to plants occurs through various processes, depending on element speciation and then, leading to varied bioavailabilities. Agricultural practices have the potential to influence the transfer of trace elements, serving as a potential lever for addressing environmental and health concerns. Notably, exogenous organic matter may act as a reactive surface and thus control the retention and bioavailability of trace elements in soils. Quantifying and qualifying accurately its role is therefore crucial for adapting agricultural management practices.

In this context, the objective was to characterize the exogenous organic matter and to assess the impact of its application on the transfer of trace elements from soil to plants in uncontaminated and gradually contaminated agricultural soils. For this purpose, we investigated the effects of exogenous organic matter application (cow manure, green waste compost, and crop residues) in a greenhouse experiment where maize was cultivated on four Belgian agricultural soils exhibiting diverse contamination levels and origins. The experiment included trace element quantification in soil, organic matter, and plant samples and characterization of exogenous organic matter mixed with soil, by nuclear magnetic resonance (solid state <sup>13</sup>C NMR), pyrolysis coupled with gas chromatography and mass spectrometry (py-GC-MS) and Rock-Eval. Results showed that both soil and exogenous organic matter highlighted some different chemical characteristics depending on the modalities considered. Those differences observed are promising for a better understanding of the relationship between organic matter and trace elements and therefore for the adaptation of agricultural management practices.

### A NOVEL TOOL FOR TRACING WATER SOURCES OF STREAMFLOW IN A MIXED LAND-USE CATCHMENT

J. CUI<sup>1</sup>, Z. SUN<sup>1</sup>, J. CHENG<sup>2</sup>, X. TANG<sup>2</sup>

<sup>1</sup> Institute of Mountain Hazards and Environment, Chinese Academy of Sciences, Chengdu, CHINA

<sup>2</sup> State Key Laboratory of Subtropical Silviculture, Zhejiang A&F University, Hangzhou, CHINA

Tracing water sources of streamflow in a mixed land-use catchment is critical for predicting pollutant emissions from various human activities to streams but remains a major challenge. A rain event based field monitoring study was conducted in the Jieliu catchment located in the hilly area of central Sichuan Province, southwest China. The ratio of the maximum fluorescence intensities ( $F_{max}$ ) of the two humic-like dissolved organic matter (DOM) components at excitation/emission wavelengths of 255 (315)/415 nm (component 1; C1) and 260 (375)/ 480 nm (component 2; C2) was proposed as a tracer for quantifying streamflow water sources. Satisfactory performance of using the  $F_{max}(C1)/F_{max}(C2)$  ratio in hydrograph separation of streamflow at the outlet of a forest sub-catchment was verified by through comparison with the hydrograph separation results based on  $\delta^{18}O$  data. The  $F_{max}(C1)/F_{max}(C2)$  ratio was then applied to estimate the contributions of rainwater and pre-event water sources under different land use types to the streamflow in an agro-forest sub-catchment and the entire catchment. The hydrograph separation results using the  $F_{max}(C1)/F_{max}(C2)$  ratio can be used to support the optimization of water resource management and the quantification of pollutant loadings from major water sources to streams at the catchment scale.

### ASSESSING COMBINED TOXICITY EFFECTS OF EMERGING POLLUTANTS AND HEAVY METALS ON *E. CRYPTICUS* IN SOIL ECOSYSTEM

I. OZTURK UFUK, E. TOPUZ, S. HANDIRI, D. AKKOC, Y.S. YILDIZ, A. WASEEM

Gebze Technical University, Kocaeli, TURKEY

Emerging pollutants pose a formidable threat to soil ecosystems, necessitating a profound understanding of their individual and combined impacts. This study explores the toxicity of benzopyrene, anthracene, diuron, carbofuran, and heavy metals (Cu and Cr) on *E. crypticus*, assessing binary and combined mixture effects using EC50 values. Individual pollutants exhibit diverse toxicity levels (1.84 to 78 mg/kg), highlighting their varied ecological implications. Binary mixtures involving benzopyrene and anthracene or diuron display reduced toxicity, while their ternary combination showcases the lowest toxicity ( $EC_{50} = 3.245 \pm 0.213$  mg/kg). Cu and Cr individually present higher toxicity (275.8 mg/kg and 222 mg/kg, respectively), with combined effects diverging from individual profiles ( $EC_{50} = 190$  mg/kg). Combining Cu or Cr with carbofuran demonstrates diminished toxicity compared to singular carbofuran ( $EC_{50} = 2.408$  mg/kg). Remarkably, the trio of Cu, Cr, and carbofuran manifests intermediate toxicity ( $EC_{50} = 2.115$  mg/kg). These findings elucidate intricate interactions within pollutant mixtures, suggesting potential antagonistic or synergistic effects on *E. crypticus*.

Understanding combined toxicity is pivotal for accurate risk assessments and effective environmental management strategies, underscoring the complexity of soil ecosystem responses to emerging contaminants.

**Keywords:** emerging pollutants, soil toxicity, *Enchytraeus crypticus*, organic pollutants, heavy metal

### FIXATION OF CESIUM BY GRANITE-ORIGIN SOIL

J.G. KIM, J.H. RYU, C.M. CHON

Korea Institute of Geoscience and Mineral Resources, Daejeon, SOUTH KOREA

Radionuclides, including  $^{134}\text{Cs}$ ,  $^{137}\text{Cs}$ ,  $^{131}\text{I}$ ,  $^{238}\text{Pu}$ , and  $^{140}\text{Ba}$ , are released through nuclear accident, nuclear test, and radioactive waste disposal, leading to potential soil contamination. Among them,  $^{137}\text{Cs}$  is a particularly harmful radioactive element due to its emission of high energy beta particles and gamma rays, combined with a half life of 30.1 years. The chemical properties of  $^{137}\text{Cs}$  are similar to those of potassium (K), rendering it highly soluble and mobile in groundwater. However, the adsorption and fixation of Cs to minerals, notably weathered micas, may reduce its mobility. The soil used in this study was collected from the C horizon of the soil developed from a Mesozoic mica granite, was air-dried, and was prepared by passing through a 2 mm standard sieve. The texture, mineralogy, cation exchange capacity (CEC), pH, water soluble cation and anion, and organic matter of the soil sample were determined (Dixon and White, 1996). The Cs adsorption properties of the soil sample were evaluated via adsorption kinetic and isotherm experiments employing a batch method. To investigate the soil sample's irreversible Cs adsorption characteristics, the desorption experiments were also conducted at 1mM of potassium (K). The sample displayed a CEC of 1.34 cmolc kg<sup>-1</sup>, organic matter content of 0.53% and sandy loam texture. Quartz, hydroxy-interlayered vermiculite, vermiculite, and kaolinite were identified as the major mineral components. The quantity of adsorbed Cs exhibited a sharp increase in the initial 3 h and subsequently progressively reached a state of equilibrium after 24 h. The dual-site Langmuir model ( $r^2 = 0.9988$ ) showed a very good fit for the adsorption isotherm suggesting the existence of multiple adsorption sites for Cs with distinct adsorption capacity. The Cs desorption only occurred when it reached 0.035% of CEC despite the presence of the competing ion (K<sup>+</sup>). The fixation of Cs on frayed edge sites, primarily ascribed to weathered mica and interpretable via the dual-site Langmuir model, may contribute the irreversible adsorption.

**Keywords:** Adsorption and Desorption, Mineralogy, Frayed edge, dual-site Langmuir model

### TRANSFER AND DISTRIBUTION OF ANTIBIOTIC RESISTANCE GENES IN THE SOIL-PEANUT SYSTEM RECEIVING MANURE FOR YEARS

Y. WANG, Z.F. YUE, X. .X. WANG

Institute of Soil Science Chinese Academy of Sciences, Nanjing, CHINA

Antibiotic resistance gene (ARG)-contaminated food from manure application is gaining widespread interest, but little is known about the distribution and uptake of ARGs in peanuts that are subjected to manure routinely. The application of manure can increase the risk of ARG contamination in peanut kernels, the long-term positioning experiment of 7-year results that the application of manure increased the abundance of ARGs in soil and peanuts by 59–72 and 4–10 fold, respectively. The abundance of ARGs from high to low was as follows: manure, shell-sphere soil, rhizosphere soil, bulk soil, stems, shells, needles, kernels, and roots. Compared to the bulk soil, higher concentrations of ARGs were detected in the rhizosphere and shell-sphere soil, which was because root exudates (e.g., sugars and organic acids) and shell exudates (e.g., amino acids and flavonoids) of peanuts may have recruited microorganisms, including ARB, and provided nutrients for microbial growth. Source-tracker analyses were used to investigate the potential source of ARGs in peanut kernels, which revealed that the ARGs in peanut kernels may be primarily absorbed by the roots from the soil. The spread of ARGs from soil to peanut kernels was driven by horizontal gene transfer (HGT) involving 143 genera, the majority of these 143 genera were Proteobacteria (41) followed by Firmicutes (35) and Actinobacteriota (32). The HGT of ARGs was the primary factor in the spread of ARGs, and Proteobacteria were the primary agents of HGT between different parts of peanut plants. Additionally, Compared to the Control treatment, norank Chloroplast in the Cyanobacteria phylum was the only significantly enriched genus among four potential hosts in the peanut kernel in the Manure treatment, it was the most important contributor to the abundance of ARGs in peanut kernels. Overall, our findings fill a gap in our understanding of the distribution patterns of ARGs in peanut plants and the migratory pathways of ARGs from soil to peanut kernels.

The global ecological problems associated with the transboundary transfer of pollutants as well as regional and local sources of environmental pollution currently require new approaches to the assessment of specific environmental cases in natural biogeocenoses. Natural environments are overloaded with hydrocarbons (HCs). At present, no oil field is free of waste.

In the Komi Republic, large oil fields are being intensively developed. The increase in the production of crude HCs significantly complicates the ecological situation in this region. Anthropogenically degraded soils are widely distributed in the production areas of oil fields, at the sites of prospecting and geophysical drilling, and along the oil pipelines and transport lines.

Tundra soils from European North-East of Russia (Republic of Komi) were studied. The concentration of HCs in the soil samples was determined by the fluorescence intensity of the hexane extract measured on the Fluorat-O2 liquid analyser. It was found that the background content of HCs in tundra soils is determined by the peculiarities of granulometric composition of parent material, as well as by the location of the soils in geochemically autonomous and subordinate landscapes.

The main amounts of HCs is accumulated in organogenic horizons: the largest, as a rule, in soils of river valleys (Fluvisols), on flat depressions, poorly drained river slopes and gentle slopes (Histosols, Gleysols and Retisols); the smallest – in watersheds (Podzols). Differentiation of HCs by genetic horizons is more pronounced in loamy automorphic soils and less – in sandy soils. All soils are characterised by an eluvial-illuvial distribution of HCs in the profile.

This work was supported by the grant of the Russian Science Foundation (No. 24-24-00144).

The identification and in situ cultivation of functional-yet-uncultivable microorganisms are important to confirm inferences regarding their ecological functions. Here, we developed a new method that couples Raman-activated cell sorting (RACS), stable-isotope probing (SIP), and genome-directed cultivation (GDC)—namely RACS-SIP-GDC—to identify, sort, and cultivate the in situ active toluene degraders from a complex microbial community in petroleum-contaminated soil. Using SIP, we successfully identified the active toluene degrader *Pigmentiphaga*, the single cells of which were subsequently sorted and isolated by RACS. We further successfully assembled the genome of *Pigmentiphaga* based on the metagenomic sequencing of <sup>13</sup>C-DNA and single-cell genomic sequencing of sorted cells, which was confirmed by *gyrB* gene comparison and average nucleotide identity determination. Additionally, the genotypes and phenotypes of this degrader were directly linked at the single-cell level, and its complete toluene metabolic pathways in petroleum-contaminated soil were reconstructed. Based on its unique metabolic properties uncovered by genome sequencing, we modified the traditional cultivation medium with antibiotics, amino acids, carbon sources, and growth factors (e.g., vitamins and metals), achieving a successful cultivation of RACS-sorted active degrader *Pigmentiphaga* sp. Our results implied that RACS-SIP-GDC is a state-of-the-art approach for the precise identification, targeted isolation, and cultivation of in situ functional microbes from complex communities in natural habitats. RACS-SIP-GDC can be used to explore specific and targeted organic-pollution-degrading microorganisms in situ at the single-cell level and provide new insights into their biodegradation mechanisms.

Permian soils in Enshi, a selenium (Se) enriched area, exhibit high background levels of cadmium (Cd), posing risks to Se-enriched agriculture. This study aims to understand the enrichment and behavior of Se, Cd, and other heavy metals in rhizosphere soils and crops. Soil samples from Enshi were analyzed, and the fractions of Se and Cd were assessed. Results showed higher Se (5.3 mg/kg) and Cd (8.22 mg/kg) concentrations in overlying soils. Se was mainly in organic-bound form (61.3%), while Cd was predominantly in the exchangeable state (62.5%). High Cd lability (75.5%) and pollution (52%) were observed in soils. Tea had the highest Se enrichment (82%) without exceeding Cd limits. Rice and maize had lower Se enrichment (9.6% and 6.0%) but higher Cd exceedance rates (61.3% and 48.5%). Edible parts of rice were more affected by soil factors than maize and tea. This study provides insights into the geochemical behavior and agronomic accumulation of Se and Cd in Enshi's high-Se and high-Cd areas, contributing to the production of safe Se-rich agricultural products.

Organochlorine pesticides (OCP) are persistent organic pollutants used to control endemic diseases in agriculture of tropical regions. In Brazil, they were widely used from the 1940s - 1990s. However, despite being banned in 2005, some are still detected in the soil, in some cases increasing the concentrations of heavy metals (HM). We evaluated the occurrence of OCP in soils of agricultural areas and its relationship with HM. Five soil samples at 0-20 cm depth were collected in each area: red roses (CA1) and chrysanthemum (CA2), and three samples in a native forest area (NFA), in Northeast, Brazil, during the dry and rainy periods, and quantified the concentration of Cd, Cu, Mn, Pb and Zn, as well as a-BHC, b-BHC, g-BHC, d-BHC, Heptachlor, Aldrin, Heptachlor epoxide, g-Chlordane, a-Chlordane, Endosulfan, 4,4-DDE, Dieldrin, Endrin, 4,4 DDD, trans-Nonachlor, Endrin aldehyde, Endosulfan sulfate, 4,4 DDT, Endrin ketone and Methoxychlor detected by gas chromatography with electron capture detector (GC-ECD). The results were subjected to ANOVA and Tukey's test ( $p < 0.05$ ). The relationship between OCP and HM was verified using Spearman's correlation ( $p < 0.05$ ). The summed concentration of OCP ( $\text{ng g}^{-1}$ ) (sum OCP) ranged from 3.33 to 29.78 (CA1), from 18.56 to 202.97 (CA2) and 5.42 to 10.34 (NFA), with no difference between the sampling periods, however, CA2 area had the highest concentrations of OCP. The levels of Cd, Mn, and Zn were positively correlated with d-BHC, Aldrin, 4,4 DDD, Endrin aldehyde and Endrin ketone. Zn also had a positive correlation with Methoxychlor and, Cu had a positive correlation with Aldrin, Endosulfan, 4,4 DDD and Endrin aldehyde. We therefore found that even after almost two decades of banning these compounds in Brazil, they can still be detected in the soil and favoring the increase of HM concentration. Our results reinforce that soil contamination by OCP residues should be considered in soil quality assessments, given the potential harmful effects of these substances on the environment and human health

Carbamazepine (CBZ) is a pharmaceutically active antiepileptic compound that can be introduced into the agroecosystem through irrigation with wastewater purified using tertiary treatments.

In this greenhouse study, we focused on the fate of CBZ and its metabolites in the soil-plant system.

To simulate pharmaceuticals accumulation in soils, the experimental design involved the use of two waters spiked with 200 and 600 ppb of CBZ.

Irrigation was carried out in pots with and without basil plants in order to evaluate the effect of the plant on the behavior of CBZ and its degradation products.

The results showed a lower concentration of CBZ and its metabolites (acridine and carbamazepine-10,11-epoxide) in soils with basil plants compared to control one and the presence of the aforementioned organic contaminants in the roots and aerial parts of basil. These results are due to the positive role of the basil rhizosphere in the degradation of this compound and/or plant in the removal of the contaminant by absorption processes.

The observed morphological parameters (plant height, number of leaves, fresh and dry weight and chlorophyll content) were not affected by CBZ, even at high concentrations. In view of the low concentration of CBZ in the effluents of wastewater treatment plants, far lower than that used in the present experiment, basil can be considered suitable for irrigation with purified wastewater. To exclude risks of toxicity for humans and environment, further ecotoxicological and biochemical studies are necessary.

The widespread use of antibiotics, such as Ciprofloxacin (CIP), to treat infectious diseases in humans and animals has raised significant environmental concerns due to the presence of these drugs in soils. This study investigates the occurrence and adsorption of Ciprofloxacin in soil, shedding light on the environmental implications associated with antibiotic use. The objective is to establish the role of different soil components, such as organic matter (OM) and iron oxides (FexOy), in the adsorption of ciprofloxacin in Andisol soils. This understanding helps establish the environmental consequences associated to the extensive use of antibiotics. The Andisol soil of Santa Bárbara (SB) series and chemically treated substrates without organic matter (SB1) and without organic matter and iron oxides (SB2) were characterized.

Adsorption isotherms reveal the presence of two types of adsorption sites in the SB soil: instantaneous and time-dependent. The Langmuir-Freundlich model effectively explains the observed cooperative adsorption, while the Freundlich model aligns well with the experimental data from SB1 and SB2 samples. SB1 exhibits a higher adsorption capacity but lower intensity compared to SB2. The removal of OM and FexOy notably influences the adsorption behavior, resulting in lower capacities compared to the original SB soil.

In brief, this study emphasizes the complex interaction between CIP and soil components, highlighting the significance of OM and FexOy in the adsorption capacity of antibiotics. Understanding these interactions is crucial for developing strategies to minimize environmental impact and sustainably manage antibiotic residues in soil. Further research in this field is essential for preserving environmental and human health, contributing to the well-being of the planet by expanding our knowledge of antibiotic-soil interactions.

Plastic production is increasing every year, and most of plastics are manufactured as a single-use items. This causes them quickly to end up as waste that is often stored in landfills. If waste management is not adequate, they can be accumulated and transported to other ecosystems, such as rivers, streams, lakes, or soil. Plastic concentration on soil is believed to be significantly higher than in aqueous environments, however, soil remains an often-overlooked player in plastic pollution. In the last decades, the impact of conventional petroleum-based plastics and microplastics has gained more prominence in the scientific community, and recently, bioplastics have emerged as one of the most promising alternatives to reduce the use of conventional polymers. Despite this, the environmental consequences of the accumulation of these novel bioplastics have not been extensively studied.

This work studies the degradation of two types of bioplastics (PLA and PHB) and a conventional plastic (PP) under natural conditions. For this purpose, 10x10 cm plastic film squares were cut into strips and buried into the soil inside nylon mesh bags with a pore size of 200  $\mu\text{m}$ . Recovery of plastics was conducted at three, five, and six months after the experiment started. Humidity and temperature conditions were monitored. Once collected, samples were washed with distilled water, removed from the nylon mesh bags, and visually evaluated for signs of degradation. FT-IR analysis was performed to assess changes in the functional groups of the plastics compared with the original material.

Visually, PHB was the only plastic that suffered degradation and loss of material. Pieces of this plastic were broken into many fragments, in this way, the formation of micro and nanoplastics were confirmed after three months. PLA and PP had no signs of degradation after six months exposure. FT-IR analyses, currently in progress, will determine whether modifications to the functional groups have occurred. The results will be presented in the poster.

Biosolids are considered an alternative to chemical fertilizers due to their rich nutrients. However, long-term biosolids application can lead to heavy metals accumulation, which severely affects soil microbial community compositions. The factors influencing soil microbial community assembly were explored under a 16-year long-term experiment with biosolids applications. Our results indicated that biosolids application significantly increased fungal richness while not for bacterial and arbuscular mycorrhizal (AM) fungal richness. Besides, biosolids application significantly affected soil bacterial, fungal compositions and AM fungal community. Soil microorganisms were clustered into different modules with bacterial and AM fungal communities were affected by both organic matter and heavy metals, while fungal communities were affected by heavy metals (Cr, Ni, and As). The soil bacterial community assembly was dominated by stochastic processes while the fungal and AM fungal community assemblies were mainly driven by deterministic processes. Random forest analysis showed that heavy metals were identified as major drivers (Hg, Cu, Cd, and Zn for bacteria, Pb and Cr for fungi, and As and Ni for AM fungi) of the community assembly process. Overall, our study highlights the significant role of heavy metals in shaping microbial community dynamics and gives a guide for controlling biosolids application.

Cadmium (Cd) is a heavy metal present in soils and has no biological function at the human or ecosystemic level. Cocoa cultivation in Colombia is experiencing difficulties due to the presence of this heavy metal in its soils, which affects the Cd content in the final products and therefore human health. Different investigations have been reported that have addressed this problem, however, little is known about the metabolic dynamics of the cocoa root-soil system, especially in those systems that present different behaviors in the fractions and contents of cadmium in the soil. For this reason, the objective of this project is to evaluate the metabolic dynamics of the root-soil system of cocoa (*Theobroma cacao* L.), with a view to determining possible relations between this and the cadmium fractions in rhizospheric soils in cocoa crops areas of the Department of Santander, Colombia. For this purpose, the physicochemical characteristics, fractions and cadmium content in soils will be evaluated, as well as the cadmium content in the respective plant tissues. The variations in the metabolic profiles present in the roots of cocoa plants and in the rhizospheric soils will be characterized. Likewise, the metabolic and enzymatic activity in the soils will be evaluated. Finally, the relationships between the different parameters determined will be analyzed globally, with a view to understanding the metabolic dynamics of the root-soil system. As well as, to promote spaces for feedback and collaborative work at national and international level, which allow the generation of regulations, standardization and governance around the management of soils with the presence of heavy metals, as well as the maximum limits allowed in food and soils. Special attention should be paid to countries where this problem has not yet been addressed in depth, putting public health, ecosystems and food safety at risk.

There has been a systematic increase in livestock production in recent years, generating organic waste and by-products that, if not properly managed, can pose a significant threat to the soil environment. So far, animal manure has been studied mainly in terms of its fertilizing value, i.e. beneficial effects on soil properties and crop yield. However, increased and repeated application of such fertilizers, and improper management or disposal, may result in the introduction of a broad spectrum of contaminants e.g. pathogens, pesticide residues and emerging pollutants (veterinary pharmaceuticals, antibiotic resistance genes or steroid hormones). The impact of the latter substances on the soil is so far not well recognized, so research has been undertaken to assess changes in soil biological activity and functional diversity in the area of intensive livestock (i.e. poultry) production. Seasonal changes in the soil environment under poultry farming pressure were an additional factor analysed.

Soil samples were collected from the top layer of two arable fields in spring and autumn 2021 respectively. Soil microbial activity was determined by analysing enzymatic activity, respiration, microbial biomass and nitrifying activity. The diversity and the metabolic potential of the microbial community was determined using the Biolog EcoPlate™ method and the average well colour development (AWCD), richness (R), Shannon diversity (S) and evenness (E). In addition, metabolic (qCO<sub>2</sub>) and microbial (MicQ) quotients were calculated and the contents of selected trace elements, anions and pharmaceuticals were analysed.

The EcoPlate results showed no statistically significant metabolic differences (S, R, E) between the communities studied, only differences in growth itself (AWCD). However, substantial differences were observed in phosphatases, nitrifying activity and microbial biomass, as well as in qCO<sub>2</sub> and MicQ quotients. In general, lower microbial activity was observed in the soil from the field with the manure pile, where excess nutrients and pharmaceutical residues (ciprofloxacin, enrofloxacin, carbamazepine and metoclopramide) were found.

This study was supported by the National Science Centre, Poland, under grant no. 2019/35/B/NZ7/04394.

<sup>1</sup> University of Padova, Legnaro (PD), ITALY

<sup>2</sup> University of Georgia, Athens, USA

Soils under agricultural production are a major source of nitrous oxide (N<sub>2</sub>O) emissions primarily through denitrification and nitrification pathways. Recently, emissions appeared to be strictly related to soil structure characteristics, which may also play a substantial role in the emission pathways. Among these characteristics, the extent to which soil compaction impacts N<sub>2</sub>O emissions is still debated. To investigate this, a two-year lysimeter experiment was set up under five different cultivation systems with four replicates each: bare soil (BS), conventional (CV), conventional + cover crop (CC), conservation with shallow soil compaction (0-25 cm, CA1), and conservation with deep soil compaction (25-45 cm, CA2). Maize (2022) and grain sorghum (2023) were grown as the main crop and fertilized using solid digestate (300 kg N ha<sup>-1</sup>). In this timespan, continuous automatic measurements of N<sub>2</sub>O emissions were collected using a non-steady state through-flow chamber system and an FTIR gas analyzer, allowing to measure up to seven fluxes for each chamber per day. In this study, we focused on the intra-daily emissions in the 30 days following fertilization. The relative importance of nitrification and denitrification to the flux of N<sub>2</sub>O was hinted at by concurrently measuring the soil NO<sub>x</sub> emissions and the water-filled pore space (WFPS) and soil temperature measured in the 0-30 cm profile. Further, soil samples at 0-5 cm and 5-15 cm depths were taken in each lysimeter in the 30-day period for a total of 320 soil samples and analyzed for pH and ammonia and nitrate pool dynamics. This comprehensive approach aims to provide valuable insights into the complex relationship between soil compaction, cultivation systems, and N<sub>2</sub>O emissions in the critical period post-fertilization.

**Keywords:** nitrification, nitrogen pool dynamics, flux, soil compaction, emission pathways

### DIFFERENT TILLAGE AND FERTILIZATION AFFECT N<sub>2</sub>O EMISSION OF ARABLE SOILS

M. DENCZO, Z. BAKACSI, S. MOLNAR, E. TOTH

Institute for Soil Sciences, HUN-REN Centre for Agricultural Research - Department of Soil Physics and Water Management, Budapest, HUNGARY

Measuring greenhouse gas emissions of arable soils is essential to evaluate mitigating techniques in climate-smart agriculture. Anthropogenic disturbances, like tillage operations and different fertilizations, alter soil nitrogen cycle and greenhouse gas emissions like N<sub>2</sub>O effluxes in the short- and even longer term.

We measured N<sub>2</sub>O emissions by the dynamic chamber method in two different long-term field experiments on chernozem-type soils from 2019 through 2022. In the tillage experiment, we compared the soil derived emissions under the conventional mouldboard ploughing (MP) and the conservational shallow cultivation (SC) and no tillage (NT) treatments, while in the fertilizer experiment we measured on NPK fertilized and organic manured parcels. Besides N<sub>2</sub>O emission, we determined the main environmental drivers, like soil temperature (T<sub>s</sub>), soil water content (SWC) and soil chemical parameters like soil organic carbon (SOC), total nitrogen (N<sub>tot</sub>), ammonium-nitrogen (NH<sub>4</sub>-N), nitrate-nitrogen (NO<sub>3</sub>-N) and pH.

Based on our results from the tillage experiment, major N<sub>2</sub>O emission occurred due to denitrification in the upper soil layer. The mean SWC and the nitrogen form values were the highest under NT, causing elevated N<sub>2</sub>O emission compared to SC or MP parcels. In addition, soil pH was the lowest under NT, hence it also contributed in soil biological processes and in the elevated emission. Regarding the fertilizer experiment, rather NPK fertilization than organic manure had major effect on N<sub>2</sub>O emission of soil caused by higher soil N<sub>tot</sub> and NO<sub>3</sub>-N contents.

The research was funded by the Sustainable Development and Technologies National Programme of the Hungarian Academy of Sciences (FFT NP FTA).

<sup>6</sup> Austrian Federal Forests, Purkersdorf, AUSTRIA

Under natural conditions temperate forests are a sink for CO<sub>2</sub> and methane while soil emissions of nitrous oxide (N<sub>2</sub>O) are low. Rewetting events and freeze-thaw cycles are known triggers for N<sub>2</sub>O emission. However, ground-based harvesting systems disturb soil conditions and can significantly increase soil N<sub>2</sub>O emissions. Logging causes severe soil compaction, soil displacement, and incorporation of organic matter (OM). These changes in soil optimize denitrification conditions. Incorporated OM in the soil matrix delivers carbon and nitrogen compounds, while oxygen gets limited due to reduced soil porosity and gas diffusivity. Soil disturbance is particularly strong and long-lasting in compaction-prone silty and loamy soils.

In an empirical study, we compare the effects of harvester-forwarder with and without tracks (HF/HFt) and cable-yarding with motor-manual-felling (CMM) on the microbial community (MBC), nitrogen balance, and N<sub>2</sub>O fluxes. N<sub>2</sub>O soil flux rates are measured with a trace gas analyzer (Li-Cor), either manually at the recently thinned stands, or continuously at plots that were thinned in 2016. Changes in the MBC were determined by phospholipid fatty acids and microbial biomass analysis. Supplementary soil analyses provide estimates for nitrogen availability and turnover.

Results show a significant impact the applied harvesting techniques on soil N<sub>2</sub>O fluxes of both skid trails and CCM corridors, compared to the control plots at the thinned stand. Our findings indicate that OM translocation and aggregation play a key role in the changes of soil N<sub>2</sub>O fluxes. In an irrigation experiment, CCM sections with high amounts of particular OM showed greater N<sub>2</sub>O fluxes than HFt skid trails. Areas with loose topsoil structure showed a tendency for elevated N<sub>2</sub>O emissions after rewetting. In a transect across a skid trail measured one day after precipitation, N<sub>2</sub>O fluxes were 2-fold higher in the middle mound compared to the ruts. Our findings underline that soil compaction is a central concern, but it is crucial to consider logging induced soil displacement and OM incorporation in research for sustainable management methods.

<sup>5</sup> Universidad de Concepción, Chillan, CHILE

Nitrous oxide (N<sub>2</sub>O) emissions contribute c. 20% of total agricultural greenhouse gas (GHG) emissions in New Zealand. The incorporation of plantain (*Plantago lanceolata*) in pastures has reportedly reduced N<sub>2</sub>O emissions through the production of secondary compounds inducing biologically nitrification inhibition (BNI), although the mechanisms associated to their release are still unclear. The experiment aimed to understand the role of pH (4.2, 5.6 and 6.8) and nitrogen (N) source (N-NH<sub>4</sub><sup>+</sup>, N-NO<sub>3</sub><sup>-</sup>) on plantain's BNI metabolites. For this, plantain and ryegrass (*Lolium perenne*, control) were sown in rockwool cubes and after 10 days the seedlings were transferred to a hydroponic system for a period of 45 days (30 L cubic tanks, 8 plants per tank), solution N concentration and pH were revised and adjusted weekly. An additional solution medium was used to collect root exudates. The concentration of aucubin, acteoside and catalpol in root exudates, leaf and root samples were determined by high-performance liquid chromatography (HPLC) and UV-Vis detector (leaf and root) or a mass spectrometer (root exudates), and data was analysed using SAS 9.6. All three metabolites were found in higher concentrations in plantain leaves and roots, in comparison to ryegrass ( $p < 0.05$ ). Higher concentrations of acteoside were found at pH 5.6 ( $0.51 \pm 0.008$  mg/g DM for pH 5.6 and  $0.45 \pm 0.013$  mg/g DM for pH 4.2 and 6.8, on average, respectively;  $p < 0.07$ ), and when N-NH<sub>4</sub><sup>+</sup> was used as N source ( $0.73 \pm 0.007$  mg mg/g DM for NH<sub>4</sub><sup>+</sup> and  $0.40 \pm 0.03$  mg mg/g DM for NO<sub>3</sub><sup>-</sup> treatments, respectively;  $p < 0.05$ ), reflecting that weakly acid conditions may favour the release of this metabolite. No significant differences between treatments were found for aucubin concentrations in plant tissue ( $p > 0.05$ ), and catalpol was not detected in leaves or roots. Aucubin, catalpol and acteoside were not detected in root exudates, with implications for the detection methodology.

Soil enzyme activities and microbiologically regulated nitrification and denitrification processes on the Tibetan Plateau are sensitive to grassland degradation and nitrogen addition. With the aim of understanding what happened to the soil nitrification and denitrification rates under the N application gradients, we set a field experiment treated with N at 6 different rates (0, 2, 4, 8, 16, and 32 g N·m<sup>-2</sup>·yr<sup>-1</sup>) in 2014. We determined the physico-chemical properties, abundances and community structures of the nitrifiers and denitrifiers, the net nitrification rate (NNR) and the potential denitrification rate (PDR) of soil samples that were collected in 2020. In addition, we conducted a meta-analysis that collected 130 papers and 881 data sets in order to investigate the effects of different degradation levels on soil enzyme activities on the Tibetan Plateau.

Soil acidification was mainly affected by the nitrification process producing in alpine meadows. The N application could change the microorganisms that dominate the ammonia-oxidizing process from AOA to AOB. High N application decreased the *nosZ* gene abundance. The community compositions of AOA *amoA*, AOB *amoA*, *nirS*, *nirK*, and *nosZ* were not affected by the N addition, which indicates that the soil microorganisms respond to the N addition preferentially with the abundance changes rather than the community composition changes. The nitrification rate was mainly explained by the nitrifier abundance (46.3%), while the denitrification rate was mainly explained by soil environmental properties (71.1%). Significant changes in enzyme activity were observed primarily during the extreme degradation stage in the Tibetan Plateau. The results demonstrated that the NNR and PDR were mainly explained by functional genes abundances and environmental factors, respectively, in alpine meadow soil under sustained N deposition.

Cover crops (CC) are an essential part of sustainable nutrient management in agroecosystems. The most promising but largely unknown functions are plant controls on microbial-mediated nutrient cycles in soil and understanding this complex process can help to improve nutrient use efficiency in agroecosystems.

In long-term field experiments in Germany, we explored a very different pattern of N uptake, gaseous or leaching losses between various CC treatments. We selected the two most contrasting CCs, clover (*Trifolium alexandrinum*) and phacelia (*Phacelia tanacetifolia*), and a fallow as a control for a temporal gradient study. We investigated soil nutrients, the abundance of microbial phylogenetic markers and functional genes of the N cycle by q-PCR and composition and diversity by amplicon sequencing from bulk soil samples. Samples were taken in autumn at the peak of biomass development, after frost kill and litter decay (winter and spring), and after the germination of the following crop, maize. Clover supported significantly higher bacterial and fungal biomass than phacelia and fallow. The structure of microbial communities was significantly influenced by treatments over time. Bacterial and fungal network complexities were significantly higher in clover than in phacelia and fallow. Higher abundance of *amoA* genes suggests a higher potential of prokaryotic nitrification activity for clover that corresponds with higher NO<sub>3</sub><sup>-</sup> in soil and a higher N-leaching potential compared to phacelia. Based on AOA/AOB ratio, phacelia showed a higher potential for nitrification inhibition. Both CC significantly increased the abundance of *nosZ* gene compared to fallow, which indicates N<sub>2</sub>O consumption in the soil and mitigation of N<sub>2</sub>O emissions.

Our results suggests that CC species have a unique fingerprint on soil microbial communities and a variable impact on their diversity, composition, network complexity and functions. Clover has a higher potential for N-fixation and mobilization but faces the risk of higher N-leaching. Phacelia has shown potential for nitrification inhibition, and both plant species reduced the nitrous oxide emission and activated a biological sink of N<sub>2</sub>O.

The reuse of organic waste as a soil amendment is promoted as a cost-effective solution to improve soil quality and agro-system sustainability. The effect of urban sewage sludge (with or without co-application of urea-N and biochar(BC)) on the N cycle, on the gaseous losses of soil N and C, and on the growth of selected plant species was studied. Positive effects were observed under the co-application of sewage sludge with inorganic N fertilization on soil fertility. However, the addition of readily degradable C and a gradual accumulation of NO<sub>3</sub><sup>-</sup>, increased N<sub>2</sub>O emissions, without significant benefit to soil C storage. Co-application of urea and organic fertilization reduced the N<sub>2</sub>O emission factor by 5x compared to urban sewage sludge but remained above 1% (IPPC). The application of sewage sludge and its co-application with urea enhanced the CO<sub>2</sub> equivalent per unit of soil C storage, by 74% and 96%, respectively, indicating the complete loss of added organic C mainly through the respiratory activity of microorganisms.

Reduced tillage intensity is known to increase soil organic carbon (SOC) in the topsoil. Its effect is positively related with microbial community, however conflicting results were reported regarding the impact on N<sub>2</sub>O emissions. In our study, two different tillage systems were studied in a long-term field experiment at the University of Ljubljana: no till (NT) and conventional tillage with mouldboard ploughing (CT); in combination with three different fertilization strategies: mineral fertilization (MIN), compost (ORG) and unfertilized control (CON). After 21 years, the data showed a clear increase of SOC in NT compared to CT at 0-10 cm depth (Govednik et al. 2023). Long-term mineral fertilisation increased the share of bacterial ammonia oxidisers in the total bacterial community (AOB/16S) which also coincided with the observed highest cumulative emissions in mineral fertilisation (Govednik et al. 2024 in revision). This ratio was proven to be one of the most important variables explaining cumulative N<sub>2</sub>O emissions, possibly reflecting the role of bacterial ammonia oxidisers in minerally fertilised soil (Figure 1). A higher genetic potential for N<sub>2</sub>O emissions was observed under NT than under CT, as indicated by an increased (nirK+nirS)/(nosZI+nosZII) ratio. Mentioned ratio under NT decreased in the order CON > MIN > ORG, indicating a higher N<sub>2</sub>O consumption potential in the NT-ORG treatment, which was confirmed in terms of cumulative emissions. The latter was indicated further by employing potential denitrification assay where significantly lower (N<sub>2</sub>O)/(N<sub>2</sub>O+N<sub>2</sub>) product ratio was observed in NT-ORG compared to the other treatments. Sequencing of 16S rRNA gene showed substantial differences in community composition between the two tillage systems while the impact of fertilisation remains to be further examined. Distinct patterns between different treatments were observed in terms of nosZI and nosZII metagenomic abundance and phylogenetic placement indicating an influence of long-term differential management on microbial community functional composition.

Most cropland soils rely on crop residues as their sole source of carbon, especially in cereal production. In the context of climate change mitigation, incorporating these residues into the soil (instead of removing them) is one popular soil management strategy to enhance the carbon input on agricultural land.

Usually, it is observed that crop residue incorporation leads to higher soil organic carbon (SOC) stocks. However, higher carbon in the soil may also modify the N<sub>2</sub>O and CH<sub>4</sub> fluxes, since these gases are produced by microbial processes mediated by carbon availability. The effect of residue management on non-CO<sub>2</sub> GHG fluxes has not been comprehensively assessed, what prevent us from estimating the overall effect of management strategies on the soil greenhouse gas (GHG) balance.

Here, we monitored GHG fluxes from a long-term experiment in the Marchfeld, a productive agricultural area in east Austria. In this experiment, two crop residue management strategies have been compared since 1982: removal of residues vs incorporation.

We used static manual chambers to estimate CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub>O fluxes between cropland and atmosphere. In parallel, soil environmental conditions and soil nutrients were investigated. We captured flux information between 902 days with a temporal resolution of approximately 21 days between measurements. Within this period the field had a rotation of winter wheat, sorghum, and triticale.

We observed a large interannual variability in N<sub>2</sub>O fluxes, from no effect to higher emissions following incorporation of residues. Cumulative N<sub>2</sub>O emissions were enhanced by incorporating residues compared to the removal treatment. Nevertheless, this amount is relatively minor compared to the currently higher SOC stocks in the first 25 cm in the residue incorporation scenario. While our case study illustrates a trade-off scenario between GHG fluxes and SOC storage in temperate croplands, the trade-off is only a small fraction of the long-term climate mitigation benefit by incorporating residues.

Ammonia oxidizers are abundant and ubiquitously distributed soil microorganisms that play an important role in the global nitrogen cycle. Despite advances in our understanding of niche differentiation and the functional importance of ammonia oxidizers over the past two decades, the recent discovery of complete ammonia oxidizers (comammox) requires novel methods to elucidate their roles and ecosystem function. Firstly, we tested the inhibitory effects of several commonly used nitrification inhibitors—acetylene, 1-octyne, 3,4-dimethylpyrazole phosphate (DMPP), 2-phenyl-4,4,5,5-tetramethylimidazoline-1-oxyl-3-oxide (PTIO), and chlorate—on nitrification by ammonia-oxidizing archaea (AOA), ammonia-oxidizing bacteria (AOB) and comammox *Nitrospira* in two wetland soils. Secondly, we conducted a microcosm experiment to assess the functional importance of AOB, AOA, and comammox *Nitrospira* in nitrification and N<sub>2</sub>O emissions in agricultural soils by using the novel method previously established. Finally, we conducted <sup>13</sup>C<sub>2</sub>O<sub>2</sub>-stable isotope probing (SIP) incubation study to test the hypothesis that the competitive intensity of AOA with AOB is lineage-specific, with the greatest intensity between phylotypes within the AOA genus *Nitrosocosmicus* and the copiotrophic AOB. The results indicate that the combined use of acetylene, 1-octyne and DMPP is a widely applicable and effective method to distinguish the relative contribution of ammonia oxidizers to nitrification and N<sub>2</sub>O emissions in soil. The sensitivity of comammox *Nitrospira* clade A to 1-octyne varied across soils, highlighting that the inappropriate use of 1-octyne can lead to misestimation of comammox activity. AOA were key ammonia oxidizers in acidic and weakly alkaline agricultural soils, while AOB dominated N<sub>2</sub>O production under conditions of high inorganic ammonia input. In contrast, comammox *Nitrospira* always played a minor role in ammonia oxidation and N<sub>2</sub>O emissions, likely due to their low abundances, restricted cellular kinetic properties and N<sub>2</sub>O production mechanisms. Furthermore, we confirmed by using SIP incubation that the AOA phylotype susceptible to AOB competition was closely related to *Nitrososphaera viennensis* EN76. Taken together, this work opens research avenues for distinguishing the activity of ammonia oxidizers and is crucial for promoting sustainable nitrogen management.

Carbon sequestration in soils is seen as a valuable contribution to climate change mitigation. Funded by the EJP Soil, the project Road4Schemes has developed a proposal for feasible and accepted systems for carbon farming based on the current experiences in European countries. Based on stocktakes, questionnaires and workshops, the demands and needs of farmers as well as administration and research in Europe have been collected and summarized. Consequently, a roadmap for the implementation of a local, regional, or even national level has been designed. The results of the project will be presented, especially focussing on gaps in knowledge and research.

**ON-FARM ASSESSMENT OF SOIL CO<sub>2</sub> EMISSIONS AFTER 7 YEARS OF DIFFERENT SOIL TILLAGE MANAGEMENT: PRELIMINARY RESULTS ON MAIZE (ZEA MAYS L.) CROP**

M. BEN HASSINE<sup>1</sup>, D. BORGATTI<sup>1</sup>, V. QUINTARELLI<sup>1</sup>, A. ZATTA<sup>2</sup>, E. RADICETTI<sup>1</sup>

<sup>1</sup> University of Ferrara, Department of Chemical, Pharmaceutical and Agricultural Sciences (DOCPAS), Ferrara, ITALY

<sup>2</sup> Research Center on Animal Production, Reggio Emilia, ITALY

It is known that the greatest emissions of carbon dioxide (CO<sub>2</sub>) from agricultural soils are due to the frequent adoption of soil ploughing. Therefore, it is necessary to evaluate the effect of alternative soil tillage practices to “conventional” plough that allow the optimal management of carbon cycle in agricultural systems. This study aimed to verify how reduced tillage practices could represent a suitable strategy for maize cultivation to reduce soil CO<sub>2</sub> emissions, while maintaining crop yield. A long-term experiment, established in 2017, in Ferrara (Italy) consisted in three different soil management practices: conventional tillage (CT), minimum tillage (MT) and old no tillage (ONT, 7 years), in addition new no tillage (NNT, started in 2023) has been included. All soil tillage practices were combined with the application of digestate, a soil amendment rich in nutrients used to enhance soil health. Maize was sown on March, 23rd and harvested on July, 26th 2023. Plots were replicated three times in a complete randomized blocks experimental design. The digestate has been applied on September, 28th 2022 in CT and MT before the soil tillage and on April, 28th 2023 (V6 growth stage) on NNT and ONT plots due to Regional regulation. Measurements of CO<sub>2</sub> emissions, soil moisture and temperature were carried out using an EGM-5 portable CO<sub>2</sub> gas analyzer and a FieldScout TDR meter, respectively at a one-week interval. Results showed that soil CO<sub>2</sub> emissions trends were lower in MT, ONT and NNT, this improves the soil ecological service of C sink and affects the carbon balance. The reduced biomass yield observed after 7 years in ONT showed the need to improve the cropping system to maintain comparable yield to CT. Soil moisture measurements showed that MT, NNT and ONT can retain moisture better thus suggesting less need for irrigation and better resistance to drought periods and reinforcing the hypothesis that soil under conventional tillage has a lower water-holding capacity and promotes nutrients leaching.

### GREEN MANURE APPLICATION, AS A TOOL FOR SUSTAINABLE N MANAGEMENT IN CROP ROTATIONS

V. PÁL, L. ZSOMBIK

University of Debrecen Research Institute of Nyíregyháza, Debrecen, HUNGARY

Given the increasing frequency of extreme weather conditions, the utilisation of N fertilizers is not guaranteed, and the application of reasonably adapted crop rotations is justified to maintain soil health. In our experiment, green manure crops were used in crop rotation systems, and the treatments were compared with N fertilized (80 kg ha<sup>-1</sup>) and control plots. The green manure species used in the experiments were common vetch (*Vicia sativa*) and oil radish (*Raphanus raphanistrum* var. *oleiformis*), and maize, triticale, and oats were used as cash crops. The experiment was set up in Hungary on humic sandy soil, in 2020 and contained four crop rotations, which allowed the evaluation of the different crop rotations in different cropyears. Precipitation had a significant effect on the biomass yield of green manure plants, which is related to the amount of CO<sub>2</sub> sequestered. For common vetch, dry biomass yields of 1.91, 0.28, and 0.60 t ha<sup>-1</sup> were measured in 2020, 2021, and 2022, corresponding to an average of 2.98, 0.44, and 0.94 t CO<sub>2</sub> sequestered per hectare, respectively. For oil radish, the values were 3.31, 0.68, and 1.36 t ha<sup>-1</sup> in the years studied, corresponding to an average of 5.16, 1.06, and 2.12 t ha<sup>-1</sup> CO<sub>2</sub> sequestered, respectively. In terms of forecrop value, in favourable year (2021), both green manure treatments were more effective than fertilization in terms of yields of triticale, oats, and maize. In 2022, an exceptional drought year, green manure treatments were equivalent for oats and significantly higher for maize yield, compared to N fertilizer. In 2023, in terms of maize yield, green manure treatments continued to be equivalent to the effect of fertilization, so in terms of crop rotation efficiency, in the 4 years studied, the application of green manures replaced a total of 320 kg of N inputs, in addition to the 4.36 tonnes and 8.34 tonnes of CO<sub>2</sub> per hectare sequestered by green manures.

EFFECTS OF 4-YEAR CONTINUOUS USE OF THE MULTIPLE INTER-TILLAGE WEEDING METHOD IN HOKKAIDO, JAPAN ON GREENHOUSE GAS BUDGET AND CARBON BUDGET

H. NAMIE<sup>1</sup>, K. SHIMADA<sup>1</sup>, S. ZHAO<sup>1</sup>, Y. TOMA<sup>2</sup>, M. ISHIGURO<sup>2</sup>, R. HATANO<sup>2</sup>

<sup>1</sup> Graduate School of Agriculture, Hokkaido University, Sapporo, JAPAN

<sup>2</sup> Research Faculty of Agriculture, Hokkaido University, Sapporo, JAPAN

Reducing CH<sub>4</sub> emission in rice paddy field is important issue in the world. Oxygen supply and plowing residues by multiple inter-tillage weeding (MIW) may effect on GHG emissions and carbon storage but there is unclear. We tested hypotheses that MIW reduces CH<sub>4</sub> emissions and improves carbon storage.

From 2020 to 2023, we investigated in paddy fields of Hokkaido University. We arranged 3 replicates of 4 treatments: without fertilizers and pesticides with MIW 0/2/5 times (T0/T2/T5) and CF with chemical fertilizers (340 kg N ha<sup>-1</sup> 4-year<sup>-1</sup>) and pesticides. GHGB was calculated by (Cumulative CO<sub>2</sub> equivalent GHG (RH (heterotrophic respiration) + CH<sub>4</sub> + N<sub>2</sub>O) emissions + Coutput - NPP (net primary production) - Cinput), and NBP was calculated by (NPP + Cinput - Cumulative (RH + CH<sub>4</sub>) emissions - Coutput). Soil temperature, redox potential (Eh), and soil physicochemical properties (NO<sub>3</sub><sup>-</sup>, SO<sub>4</sub><sup>2-</sup>, etc.) were measured. GHGs were measured by chamber methods. However, CH<sub>4</sub> and N<sub>2</sub>O emissions during MIW treatments were estimated by acrylic chamber with MIW function in 2023, which were 2.31% and 2.53% of total CH<sub>4</sub> and N<sub>2</sub>O emissions in T2, respectively and 6.86% and 14.6% of the total emissions in T5, respectively. Therefore, 4 years total emissions were modified by those proportions.

GHGB were T0 < T2 < CF < T5 (14.7, 17.5, 24.2, 31.2 Mg CO<sub>2</sub>-eq ha<sup>-1</sup> 4-year<sup>-1</sup>, respectively)<Fig.1(a)>. NBP were T5 < T2 < CF < T0 (-4.73, -2.37, -1.75, -1.34 Mg C ha<sup>-1</sup> 4-year<sup>-1</sup>, respectively)<Fig.1(b)>. RH contributed 2.0 and 20 times more than CH<sub>4</sub> to GHGB and NBP, respectively. RH correlated with SO<sub>4</sub><sup>2-</sup> and NO<sub>3</sub><sup>-</sup>, indicating that MIW oxidized promoted RH generation. Therefore, contrary to our hypotheses MIW promoted microbial respiration and organic matter decomposition, which decreased NBP and increased GHGB. Grain yields were T0 < T2 < T5 < CF (9.56, 12.4, 13.7, 23.5 Mg ha<sup>-1</sup>, respectively). GHGI (GHGB/yield) was highest in T5 as there was not enough yield to offset GHG emissions.

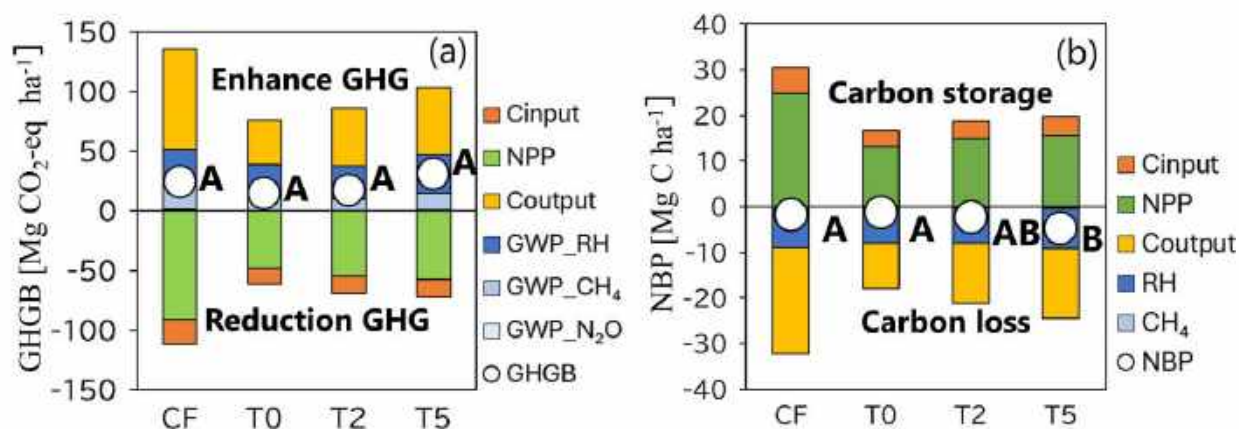

Fig.1 The results of (a) 4-year GHGB, (b) 4-year NBP.

※Error bars are standard deviations. Value with the same letters are not significantly different (p<0.05).

### A COMPREHENSIVE ANALYSIS OF SOIL HEALTH INDICATORS IN A LONG- TERM CONSERVATION TILLAGE EXPERIMENT

K. JUHOS<sup>1</sup>, P.A. NUGROHO<sup>1</sup>, G. JAKAB<sup>2</sup>, Z. KOTROCZÓ<sup>1</sup>, N. PRETTL<sup>1</sup>, Z. SZALAI<sup>2</sup>, B. MADARÁSZ<sup>1,2</sup>

<sup>1</sup> Department of Agro- Environmental Studies, Hungarian University of Agriculture and Life Science, Budapest, HUNGARY

<sup>2</sup> Geographical Institute, Research Centre for Astronomy and Earth Sciences, Budapest, Hungary, Budapest, HUNGARY

Conservation tillage (CT) is a ploughless tillage with a reduced number of operations, and its positive effect on soil functions and health is widely known. Multivariate analyses are required to choose indicators that adequately characterize the changes in soil health. However, there is little research on the comprehensive analysis of the full spectrum of soil physical, chemical, and biological properties. Therefore, we examined 21 soil parameters in a long-term CT experiment conducted in Hungary. Four pairs of similarly sized CT and conventional ploughing tillage (PT) plots were set up in 2003 on Luvisols. The soil samples were collected after 17 years. The total organic carbon (TOC) increased significantly in the 0–15 cm layer at CT sites compared to those in PT, indicating a total increase of 5.22 t per ha TOC stock. In addition, the increasing biological activity and improved soil structure were the most important processes at the CT sites. Furthermore, more complex humic substances with higher molecular weights are characteristic of water-extractable organic matter (WEOM) as a result of CT. The potentially available nitrogen, phosphorus, and potassium were also measured with a relatively high response ratio. Slowly changing parameters, such as cation exchange capacity and base saturation, are important soil physical and chemical parameters, but are not good indicators of the impact of tillage practices. Based on the principal component analysis, we suggest the use of water-extractable organic C, amino-nitrogen, water-stable aggregates, available P and K, and photometric analysis of WEOM to identify the soil-improving processes.

The authors express their cordial thanks to the National Research, Development, and Innovation Office (No. K143005) and Syngenta Hungary Ltd. for their technical and financial support.

### MULTI-CRITERIA MONITORING OF SOIL C SEQUESTRATION FOR CARBON FARMING PRACTICES IN CENTRAL EUROPE

M. MAZZON <sup>1</sup>, G. FALSONE <sup>1</sup>, A. PAESANO <sup>1</sup>, M. DI BONITO <sup>1,2</sup>, C. MARZADORI <sup>1</sup>

<sup>1</sup> DISTAL, Department of Agricultural and Food Sciences, Alma Mater Studiorum University of Bologna, Bologna, ITALY

<sup>2</sup> ARES, School of Rural, Animal and Environmental Sciences, Nottingham Trent University, Brackenhurst campus, Southwell, UNITED KINGDOM

The Central Europe Interreg Carbon Farming project is working on the introduction and adoption of carbon farming practices, business models, monitoring solutions and policies to improve the role of the agricultural sector in reducing greenhouse emissions and storing soil organic C in 9 Central Europe countries.

In this context, our aim was the study of different soil C monitoring strategies using a multi-criteria framework for the direct or indirect assessment of soil C sequestration of different C farming techniques. The monitoring strategies have been defined at different levels of complexity, so that they can be used for farmers self-assessment (visual soil assessment, VSA) and for independent audits (for 0-30 cm soil depth: C stock, enzyme activities and related Soil Quality Index, SQI).

This study was conducted on long-term field experiments (started in 1966) on Udifluventic Haplustepts, at the experimental farm of the University of Bologna (Italy); two C farming approaches were assessed: crops rotation (continuous corn, continuous wheat, wheat-corn rotation, and a nine-year rotation including wheat-corn-alfalfa rotation) and organic fertilization (manure addition, crop residues).

On average VSA, C stock and SQI values were  $25 \pm 5$ ,  $42.9 \pm 13.3$  Mg ha<sup>-1</sup> and  $29.0 \pm 7.7$ , respectively. Soil microbial biomass C (MBC) was  $67.8 \pm 28.4$  mg kg<sup>-1</sup> and  $\delta^{13}C$  was  $-23.26 \pm 1.66$ ‰ ( $\delta^{13}C$  mean value without considering the continuous corn rotation was  $-23.54 \pm 1.39$ ‰,  $\delta^{13}C$ -NOC). Both VSA, C stock and SQI were significantly negatively correlated to  $\delta^{13}C$ -NOC ( $r_s$  from -0.709 to -0.455,  $p < 0.05$ ), while VSA and C stock were positively correlated to MBC ( $r_s = 0.633$  and  $0.419$ ,  $p < 0.05$ , respectively). Our results suggest that in these soils a weak isotopic fractionation occurring during soil organic matter turnover led to improving soil quality and increase C stock. This occurred where C farming practices (i.e., nine-year rotation and manure addition) enhanced soil conditions to favour microbial biomass growth and enzyme activity efficiency.

The advantages and disadvantages of each C farming monitoring strategy were also drawn to support stakeholders in choosing the most appropriate one.

### SHORT-TERM EFFECTS OF BIOCHAR AND COMPOST ON SOIL NUTRIENT CYCLING AND LETTUCE (*LACTUCA SATIVA* L.) YIELD IN A MEDITERRANEAN ENVIRONMENT

S. MARINARI<sup>1</sup>, L. MASSACCESI<sup>1,4</sup>, I. NOGUES<sup>2</sup>, V. MAZZURCO MIRITANA<sup>2,3</sup>, L. PASSATORE<sup>2</sup>, M. ZACCHINI<sup>2</sup>, E. PERUZZI<sup>2</sup>, S. CARLONI<sup>2</sup>, R. MARABOTTINI<sup>1</sup>, M.C. MOSCATELLI<sup>1</sup>

<sup>2</sup> Research Institute on Terrestrial Ecosystems, National Research Council (IRET-CNR), Montelibretti, Roma, ITALY

<sup>3</sup> Bioprocesses for Energy and Industry Laboratory -(TERIN BBC PBE) ENEA, Roma, ITALY

<sup>4</sup> National Research Council of Italy, Institute for Agriculture and Forestry Systems in the Mediterranean (ISAFOM-CNR), Perugia, ITALY

Despite the use of biochar as a soil amendment has been widely studied, it is still not clear its effects on soil biochemical properties related to nutrient cycling and vegetable yield in a Mediterranean environment. To test the short-term effects of biochar, alone or in addition to compost, on soil nutrient cycling and lettuce (*Lactuca sativa* L.) yield, a randomized block field trial was set up within an experimental area of about 500 m<sup>2</sup>. The soil of the study area is developed from sandy and calcarenitic deposits and is classified as Calcaric Cambisols (IUSS WRB, 2022). The four treatments tested were: 1) Control (C); 2) Compost (CMP); 3) Biochar (BIO); 4) Compost-Biochar mixture (CMP+BIO). Soil sampling was performed nine months after soil amendment spreading. To evaluate the efficiency of the treatments, *L. sativa* was cultivated as an indicator of soil fertility. The biomass of lettuce was increased in all amended soils with respect to the control; the CMP amended soil showed the highest effect on microbial biomass activity (increase in  $\beta$ -glucosidase, synthetic enzymatic index and butyrate esterase) and structure (increase in G- bacteria, total fungi and AMF), indicating that the organic matter provided by the compost is more readily mineralized than that added with the biochar. Moreover, the biochar derived from pruning wastes, resulted in the lowest metabolic quotient (qCO<sub>2</sub>) and ecoenzymatic C:N ratio and the highest microbial quotient (qMIC), indicating the process of C immobilization into the microbial biomass and a greater limitation of N than C, offset by an increase enzyme activity involved in N-cycling. In the short-term, even if the number of well-developed plants increased in all amended soils, an unbalance of soil C and N cycling was evident with CMP and BIO amendments which was not re-equilibrated in CMP+ BIO, probably because requiring longer period. For this reason, long-term field experiments are needed for further investigations on the effect of biochar soil amendment on nutrient cycling.

**ASSESSING BIOCHAR FROM OLIVE PRUNINGS FOR LONG TERM SOIL RECARBONIZATION IN SPANISH OLIVE ORCHARDS: A SOIL C MODELLING APPROACH.**

F. CONTRERAS RODENAS<sup>1</sup>, E. RONCHIN<sup>2</sup>, M.L. CAYUELA<sup>1</sup>, C. MONDINI<sup>2</sup>, M.A. SÁNCHEZ-MONEDERO<sup>1</sup>

<sup>1</sup> CEBAS-CSIC, MURCIA, SPAIN

<sup>2</sup> CREA Research Centre for Viticulture and Enology, GORIZIA, ITALY

The utilization of biochar derived from olive prunings presents a sustainable way for enhancing soil organic C stocks in olive orchards. This study investigates the feasibility of using biochar from olive pruning residues for recarbonising agricultural soils from olive orchards in Spain as a strategy to mitigate the impact of the whole oleiculture sector to climate change. Soil recarbonisation will be investigated by the adoption of biochar production and soil application as a negative emission technology (NET), aimed at the net removal of atmospheric CO<sub>2</sub>. As a first step, this study estimates the olive pruning residue generation in Spain to provide context for the potential impact of integrating biochar into soil management practices. Subsequently, the Roth-C model modified for amended soil is employed to project the long-term impact of incorporating biochar at two different application rates on soil organic C stocks. Preliminary results suggest that adding biochar derived from olive pruning residues has the potential to significantly augment soil organic C content in the long term. The integration of biochar into soil management practices represents a promising strategy for sustainable agriculture, with implications for mitigating the environmental impact of olive cultivation.

**EFFECT OF MYCORRHIZA INOCULATION DEPENDING ON FERTILIZATION LEVEL AND SOIL TYPE AT A CENTRAL EUROPEAN FIELD TRIAL**

N. PRETTL, K. JUHOS, P.A. NUGROHO, Z. KOTROCZÓ, S. KABALAN, F. KOVACS, B. BIRÓ

Hungarian University of Agriculture and Life Sciences, Budapest, HUNGARY

Due to the greater pressure on soil resources and climate worldwide, in recent years, there has been a significant increase in the use of microbial inoculants, which are expected to help reduce fertilizer demand and mobilize the potential nutrients in soils. This research presents the results of a 4-year field trial that investigated how mycorrhiza inoculants (*Funneliformis*, *Claroideoglomus*, *Rhizophagus*) affected soil biological indicators and corn and wheat development depending on fertilization level and soil types. The experiment was conducted on siltic Luvisols (pH=4.91; SOC=0.94%; available P=29 ppm) and silty clay Gleysols (pH=6.75; SOC=1.45%; available P=133 ppm). Conventional fertilizer levels (NPK) in the first three years and a significantly reduced fertilizer application in the fourth year were applied combined with inoculation. The root colonization of mycorrhiza, the phosphatase enzymes of soils, shoot biomass, plant height, grain yield, root neck diameter, chlorophyll, and root capacity were measured. During the four years, precipitation amount had the greatest influence on grain yield and plant development parameters, and conventional fertilizer use increased the grain yield and shoot biomass by 25% compared to reduced fertilizer use. The mycorrhiza treatment led to higher root colonization every year compared to the control but higher biomass, height, and yield differences were found only with a strong decrease of fertilizer use on the poor nutrient content Luvisols. Despite the reduction in fertilization, the root colonization did not increase, which may have been due to improved soil nutrient availability in the wetter year, so plants were not as dependent on the mycorrhiza as in drier years. The soil organic matter was decisive in the plant development because the higher easily accessible organic substrate and microbiological activity on Gleysols contributed to higher yields and reduced the effect of fertilizers and mycorrhizal inoculation. We found that, at a reduced fertilization level, using mycorrhiza inoculation in these fields was not economically profitable because it only partially replaced the yield-increasing effect of fertilizers.

### AGREENA AS A TOOL TO SUPPORT SCALING CARBON FARMING IN EUROPE – TOOLS AND METHODS FOR SOIL ORGANIC CARBON QUANTIFICATION AND VERIFICATION

P. GEORGIADIS, M. O'NEIL, M. ALVES, R. MCDONALD

Agreena, COPENHAGEN, DENMARK

Carbon farming plays a key role in climate change mitigation and promote sustainable production of food feed and fiber. Adoption of practices such as the use of cover crops, crop rotation, no-till farming, and the addition organic matter to the soil such as crop residues, may require time and significant resources to establish a successful production and are therefore overlooked at scale. The carbon credit market can prove an important tool to support farmers transition to carbon farming. Agreena is a carbon program project developer with the aim to support farmers make this transition. Our work presents the opportunities raised by the carbon markets to lead a large-scale transformation of the agricultural landscape to climate friendly solutions in Europe, by giving farmers an economic incentive to adopt carbon farming practices and increase biomass input to their soils. We showcase the tools and data used to deliver a scalable and scientifically sound methodology of soil organic carbon modelling and verification processes. We further delve in the methods for verification and quality control of all data and result outputs for the valorization of the different carbon practices implemented in individual fields.

**RESPONSE OF QUALITY INDICATORS AND SUSTAINABLE SOIL MANAGEMENT TO THE APPLICATION OF ECOLOGICAL AGRICULTURE TECHNIQUES IN COFFEE FARMERS UNDER DIFFERENT ENVIRONMENTAL CONTEXTS IN COLOMBIA**

L.M. AVELLANEDA-TORRES

Departamento de Química. Facultad de Ciencias. Universidad Nacional de Colombia, Bogotá, COLOMBIA

With the objective of evaluating the response of soil quality indicators in the sustainable management and application of ecological farming techniques in coffee crops in Colombia, the following three processes were carried out: 1. Application of ecological farming techniques in coffee plantations under different coverings (banana, mandarin, and a mix of citrus fruits) in San José de Pare. 2. Application of the same techniques on soil characteristics in coffee plantations of varying ages (zero, two, and four years) in San Francisco. 3. Evaluation of the quality of the soil associated with the use of mycorrhizae in coffee plantations in Sasaima. In the three cases, physicochemical parameters of the soil, enzymatic activities of the biogeochemical cycles of carbon, nitrogen and phosphorus and abundance of functional groups associated with the same cycles were determined. Additionally, in the last two processes, microorganisms associated with the nitrogen cycle (ammonifying, proteolytic, ammonium oxidizing, nitrite oxidizing and denitrifying) were evaluated. In the first two processes the results showed modifications in the soil quality indicators as a consequence of the application of ecological agriculture techniques. In the three-process finding a significant increase in the content of carbon and phosphorus. In the first process finding a significant increase phosphate solubilizing bacteria and fungi, and cellulolytic fungi. In contrast, no significant changes were observed for enzymatic activity. For the second increased abundance of phosphate solubilizing fungi and cellulolytic fungi were found. Conversely, significant decreases in pH and b-glucosidase enzyme activity were observed. However, no statistically significant changes were found in the abundance of microorganisms in the nitrogen cycle. For the third process, the mycorrhizae inoculation significantly increased of nitrogen-fixing bacteria, phosphate-solubilizing bacteria, cellulolytic bacteria, and phosphate-solubilizing fungi. In addition, the local native mycorrhizae that were isolated by the authors showed greater benefits than those of the commercial mycorrhizae. However, the abundance of the functional groups of the nitrogen cycle did not present significant differences.

### TECHNOLOGICAL INNOVATION AND RESISTANCE IN CREDIBLE CARBON FARMING

P. RAJEWICZ<sup>1</sup>, J. ATHERTON<sup>1</sup>

University of Helsinki, Institute for Atmospheric and Earth System Research, Helsinki, FINLAND

Over the last decade, there has been a rapid development in new sensor and digital technologies, including, for example, innovations in proximal sensing and digital mapping. In terms of Carbon Farming, these developments bring both opportunities and challenges. One of the greatest challenges now is to efficiently incorporate and connect diverse new technologies into monitoring, reporting, and verification (MRV) systems required for the EU-level Carbon Farming certification scheme.

Within Credible Action, an EU-funded initiative focused on Carbon Farming, we - as one of the action's focus groups - work towards characterizing the current extent, interconnectedness, and possible future roles of innovative digital technologies in Carbon Farming. The focus group has a wide scope covering - but not limited to - proximal sensing, digital mapping, artificial intelligence, and farmers' perspective. We gather facts, perspectives, and opinions concerning what new technologies should be implemented across Europe and why, we investigate how the implementation of these technologies should be carried out, and what the constraints are that keep land (farms, forests, peatlands) users away from implementing the innovations.

Understanding this land users' perspective is our key aim, as we believe listening to the end-users' needs, ambitions, and worries is the best way to introduce and effectively maintain good Carbon Farming practices across Europe. Here I will present our recent survey of emerging technologies - digital tools and proximal sensing methods - together with their possible limitations. Then I will discuss the need for crystallization of the current and future role of innovative technologies in MRV systems. Lastly, I will discuss current and future barriers to their adoption, or technological resistance, suggesting a path forward.

### APPLICATION OF ROTHAMSTED CARBON MODEL INTEGRATED GIS ON SOIL ORGANIC CARBON TURNOVER OF REGIONAL CROPLAND IN NORTH CHINA PLAIN

H. LI, X. LIU, Y. LEI

The Center for Agricultural Resources Research, Institute of Genetics and Developmental Biology of CAS, Shijiazhuang, CHINA

Rothamsted carbon model is a model for the turnover of organic carbon in non-waterlogged top soils that allows for the effects of soil type, temperature, moisture content and plant cover on the turnover process. Since RothC model has been validated in cropland experiments in the NCP, this study develops a regional version of RothC model using ArcGIS ArcObjects for model application in this area. The regional model is tested by simulating soil organic carbon dynamics of the intensive winter wheat-summer maize cropland under different organic manure and stubble management practices in the Baiyangdian Basin of the North China Plain. RothC model has four active and one inert SOC compartments or pools: Decomposable Plant Material (DPM), Resistant Plant Material (RPM), Microbial Biomass (BIO), Humified Organic Matter (HUM) and the Inert Organic Matter (IOM). Variability of SOC and four components defined by RothC model in cropland of seventeen plain counties in the Basin in a short period of two years are calculated by a step of month. Range of increase of SOC in depth of 30 cm is 3.15-4.49 t C ha<sup>-1</sup> in six counties, 2.11-2.44 t C ha<sup>-1</sup> in three counties, 1.14-2.1 t C ha<sup>-1</sup> in two counties, 0.8-1.13 t C ha<sup>-1</sup> in three counties and 0.53-0.79 t C ha<sup>-1</sup> in three counties, respectively, with the application of wheat and maize straw. Ranges of differences of DPM C, RPM C, BIO C, HUM C of cropland soil among above counties caused by application of straw are 0.14-0.70 C ha<sup>-1</sup>, 0.28-1.13 C ha<sup>-1</sup>, 0.04-0.27 C ha<sup>-1</sup> and 0.04-0.12 C ha<sup>-1</sup> respectively. Considering the performance of the regional model in calculating spatial and temporal variability of SOC, this regional could be used to evaluate the turnover of soil organic carbon on regional cropland under different field managements of promoting carbon sequestration.

### IMPACT OF ORGANIC MANAGEMENT SYSTEM ON SOIL CARBON SEQUESTRATION IN THE CENTRAL REGION OF ITALY

A. KUMAR, G. ANTONIELLA, R. MARABOTTINI, S. MARINARI, E. BLASI

Department for Innovation in Biological, Agro-food and Forest Systems, University of Tuscia, Via San C. De Lellis snc, Viterbo, ITALY

The Mediterranean area, particularly Italy, is a European biodiversity hotspot with diverse ecosystems facing climate change impacts. Agriculture, vital for food security, significantly contributes to greenhouse gas (GHG) emissions, often relying on harmful inputs like excessive synthetic chemical fertilizers and pesticides. Sustainable techniques, such as carbon (C) farming practices, are critical not only for mitigating climate change but also for improving soil health and nutrient availability while establishing a favourable environment for soil organisms by controlling soil organic C (SOC) levels. Thus, this study aims to investigate the quantity of C in the bulk mineral soil and its distribution in fractions with different stability (e.g., labile vs. recalcitrant) in three agricultural farms from different regions of Central Italy where conventional and organic management systems were compared. Furthermore, the study also develops a better understanding of the impact of organic management systems on storing C and possibly retaining it for a longer period of time than conventional systems. At each sampling site, five mineral soil samples were collected at the depths of 0-15 and 15-30 cm, to determine the total SOC stock. Additionally, the distribution of SOC in labile and recalcitrant fractions was evaluated using an acid-alkali extraction method. The results showed a dynamic response, where organically managed soils at both depths had significantly higher levels organic C compared to conventionally managed soils, but the distribution of C in labile and recalcitrant fractions does not reveal any clear trend that can be related the stability of the C in the soil system. This study is suggestive that organic management systems enhance soil C sequestration, but it is still unclear the impact of this management system on the long-term permanence of the C that leads to a decline in GHG emissions. Additional research is essential to finally evaluate the permanence of C in the soil system in relation to organic management.

**Keywords:** Carbon farming, Labile carbon, Organic management, Recalcitrant carbon, Soil organic carbon

### IMPACT OF REDUCED TILLAGE ON SOIL C AND N POOLS AND MICROBIAL FUNCTIONAL DIVERSITY UNDER ORGANIC MANAGEMENT IN A MEDITERRANEAN ENVIRONMENT

M. BEN HASSINE<sup>1</sup>, R. MANCINELLI<sup>2</sup>, M.C. MOSCATELLI<sup>3</sup>, E. RADICETTI<sup>1</sup>, R. MARABOTTINI<sup>3</sup>, S. MARINARI<sup>3</sup>

<sup>1</sup> University of Ferrara, Department of Chemical, Pharmaceutical and Agricultural Sciences (DOCPAS), Ferrara, ITALY

<sup>2</sup> University of Tuscia, Department of Agricultural and Forestry Sciences, Viterbo, ITALY

<sup>3</sup> University of Tuscia, Department for Innovation in Biological, Agrofood and Forest Systems, Viterbo, ITALY

The conventional agricultural system, based on soil inversion tillage, is a weak system in terms of its environmental impact and low biodiversity, compared to the organic system, defined as a sustainable system that allows to enhance the soil fertility and quality and use of environment-friendly techniques such as cover cropping. The aim of this study was to assess the impact of conventional and organic agricultural systems on C and N stocks and soil quality after 14-year long-term experiment in a Mediterranean environment by focusing on C and N pools and soil quality bioindicators such as microbial biomass size and activity. For this objective, a long-term experiment (LTE) located at University of Tuscia experimental farm (Viterbo, Italy) was established in 2001 with the objective to study conventional (CONV) vs. organic (ORG) systems and ploughed (30 cm, CT) vs. reduced tillage (RT). A 3-year crop rotation [pea, durum wheat and tomato] was established in both cropping systems and replicated as a randomized block design. Soil samples were collected at two soil depths (0-15 cm and 15-30 cm). Over 14 years of management, the ORG-RT management showed an increase of 25% (+3.75 Mg C ha<sup>-1</sup>) of C stock with respect to the CONV-CT management. The soil microbial biomass and the microbial quotient were positively influenced by the ORG system, probably due to the cover crop incorporation as green manure. The sum of enzyme activity involved in the C-cycle (SEI-C) at both soil depths, showed the greatest values under ORG-RT system. Moreover, the C-cycle specific enzyme activity was influenced by tillage at 0-15 cm (RT>CT). Enzyme activities reflected the effect of system management (per unit of soil) while the tillage effect was registered only for the specific enzyme activity (per unit of organic carbon). The management system was also marked at 15-30 cm soil depth in terms of SEI-C and Phosphatase activities. LTE is an efficient tool in assessing the agricultural management sustainability.

### IMPACT OF COPPICE CONVERSION TO HIGH FOREST ON CLIMATE CHANGE MITIGATION. A CASE STUDY FROM BROADLEAVES FORESTS IN CENTRAL ITALY

G. FANTONI <sup>1</sup>, T. CHITI <sup>2</sup>

<sup>1</sup> University of Florence (UniFi)-Department of Agriculture, Food, Environment and Forestry (DAGRI), Florence, ITALY

<sup>2</sup> University of Tuscia-Department for Innovation in Biological, Agro-food and Forest Systems (DIBAF), Viterbo, ITALY

Under the threat of climate change for terrestrial ecosystems and the society, carbon (C) sequestration represents one of the key ecosystem services provided by forests. The capacity of forests to store additional amount of C is limited by the current increase in the demand for wood products by the increasing global population, which represents a further pressure on forest ecosystems. In this work we evaluated the mitigation potential, offered by the conversion from coppice to high forest stands, of the C at an ecosystem level but focusing on the contribution of the C stored in the top 30 cm of mineral soil. In this purpose, apart from the SOC stock, we applied an acid-alkali extraction methodology to investigate the distribution of the SOC fractions with a possible different stability (e.g., labile vs. recalcitrant). Two different forest typologies, located in the central Italian Apennine, were considered: a) beech stands (*Fagus sylvatica*) and b) mixed broadleaves (e.g. *Ostrya carpinifolia* and *Fraxinus ornus*). Results indicated an increase of C stored in the living biomass for beech stands two decades from the conversion and promising results regarding mixed broadleaves stands. No significant changes were observed in the SOC stock before and after almost two decades from the intervention, suggesting a minor effect of the conversion cut. The fractionation results showed a dynamic response revealing a fluctuation of C in the labile and recalcitrant organic fractions between the forest types. The variation of C measured in this study suggests that, although the amount of C stored in a forest ecosystem can increase after sustainable practices application, these variations are distributed amongst C pools with different turnover time. In conclusion, in the investigated area this type of forest intervention lead to an increase of C at an ecosystem level and seems promising for the delivery of additional ecosystem services.

### THE SOIL CARBON STOCK UNDER NO-TILL FARMING IN RUSSIAN FOREST-STEPPE REGION

L. MIRNYI<sup>1</sup>, S. SUSHKO<sup>1</sup>, O. SUKHOVEEVA<sup>1, 2</sup>, Y. DVORNIKOV<sup>1, 3</sup>, L. ORLOVA<sup>4</sup>, N. ANANYEVA<sup>1</sup>, K. IVASHCHENKO<sup>1</sup>

<sup>1</sup> Institute of Physicochemical and Biological Problems in Soil Science, Pushchino, RUSSIA

<sup>2</sup> Institute of Geography, Moscow, RUSSIA

<sup>3</sup> Peoples Friendship University of Russia, Moscow, RUSSIA

<sup>4</sup> LLC Orlovka - AIC, Stary Amanak, RUSSIA

A useful tool for climate change mitigation is the ability of soil to store organic carbon (SOC). Agricultural soils with conservation agriculture technologies have a high capacity to store SOC. One of these technologies is no-tillage. The capacity of Chernozems in SOC storage under no-tillage was tested in cooperation with the agricultural enterprise Orlovka - AIC (54.181°N, 50.322°E, Samara region, Russia), which has been using this technology for the last 12 years. Two agricultural fields were selected on the farm: no-tillage for 5 and 8 years (88 and 161 ha, respectively). The neighboring field (42 ha) under conventional tillage – ploughing was selected for comparison. In each field, 30 sites were selected for soil sampling from the topsoil (0-10 cm) and subsoil (10-30 cm). We have used model-based sampling design i.e. conditioned Latin Hypercube sampling with a range of morphometric predictors.

Compared to conventional tillage, a significant increase of SOC stocks was found in the topsoil under no-tillage during 5 and 8 years (on average by 0.57 and 0.45 kg/m<sup>2</sup>, respectively), while for the subsoil a significant difference between treatments wasn't observed. In general, SOC stocks in the upper 30 cm layer increased by 0.61 and 0.34 kg/m<sup>2</sup>. Consequently, the SOC accumulation rate under no-tillage could reach up to 0.43-1.22 t C/(ha\*yr). However, the proposed assessment approach could lead to an overestimation of the SOC accumulation rate as it is based on comparative data analysis with conventional tillage. In this context, SOC stock dynamics under no-tillage were modelled from 2017 to 2022 using DNDC (DeNitrification-DeComposition model). The model showed that the SOC accumulation rate under no-tillage could range from 0.02 to 1.07 t C/(ha\*yr) depending on the climatic conditions of the year and the type of crop. Thus, no-tillage could be a useful tool for conserving SOC stocks in a studied region.

The study was carried out within the framework of the state assignment No. 122111000095–8.

**Keywords:** Conservation agriculture, SOC accumulation rate, DNDC, Chernozems

<sup>3</sup> National Biodiversity Future Center (NBFC), Palermo, ITALY

This study evaluates the impact of adopting municipal solid waste (MSW) compost as a carbon farming practice in agricultural supply chains (olive oil, wine, cereals/oilseeds and vegetables).

The MSW compost, derived from the municipal organic fraction of waste collected from the city of Florence (Tuscany, Italy), has been applied to typical crops of the Tuscany Region (olive tree, wine vine, sunflower and cardoon for the first year of research activity).

For each crop, one plot (about 1 ha) has been subjected to different treatments in three different farms: conventional fertilizer as usually applied by the farm (control), MSW-compost, and MSW-compost mixed with commercial bio-stimulants.

A three-year multidisciplinary monitoring plan (2023-2026) was planned to evaluate soil health, the physiological and functional state of the crops, and greenhouse gas (GHG) emissions from the soil.

Particular attention will be given to the potential carbon sequestration in soil by evaluating particulate and mineral-associated organic matter, and to the evaluation of eco-enzyme stoichiometry ratios.

After one year of monitoring, preliminary results demonstrated that the crops responded well to the compost treatments, with an excellent eco-physiological status, and that soil organic carbon and nitrogen stocks significantly increased.

Furthermore, the Life Cycle Assessment will identify the advantages and hotspots in each supply chain in relation to the fertilisation system.

### RESTORING DEGRADED CROPLAND WITH AMP CATTLE GRAZING: A FOCUS ON SOIL CARBON FRACTIONS

W. BRINKERHOFF<sup>1</sup>, P. STANLEY<sup>2</sup>, T. BOWLES<sup>2</sup>, J. BLESCH<sup>1</sup>

<sup>1</sup> University of Michigan, Ann Arbor, USA

<sup>2</sup> University of California, Berkeley, Berkeley, USA

Today's worsening climate crisis and increasing global demand for food makes agricultural sustainability an urgent priority. Employing ecological principles to manage farms as agroecosystems can help produce food more sustainably. In particular, Adaptive Multi-Paddock (AMP) cattle grazing, characterized by short grazing intervals and strategic rest periods, has emerged as a key agroecological practice that can help achieve sustainable development goals by building soil organic carbon (SOC). However, existing studies on AMP grazing often overlook the distinction between soil carbon fractions, such as mineral associated organic matter (MAOM) and particulate organic matter (POM), which play different functional roles in soil. This gap in knowledge hinders a comprehensive understanding of the practice's implications for climate change mitigation alongside other ecosystem services. To address this gap, we asked: 1) how do transitions from row crop production to AMP grazing affect the potential for soil C sequestration? And 2) how does AMP grazing influence C accrual in POM and MAOM fractions of SOM? We collected and analyzed soil samples from ten fields in Southeast Michigan USA to compare conventional corn/soybean rotations with forage-seeded fields subjected to five years of AMP cattle grazing. Topsoils (0-15 cm) in AMP-grazed pastures contained 13% higher total organic carbon compared to row crop fields. On average, AMP pastures had significantly more MAOM-C (24.15 g C / kg dry soil compared to 22.1 g C / kg dry soil in row crop fields). Notably, grazed pastures had a 15.1% higher concentration of POM-C, and 2.8-fold higher microbial biomass (measured with PLFA) than row cropped fields. Microbial turnover of POM is a known mechanism of MAOM accrual; our results thus suggest the potential for longer-term C sequestration with AMP grazing. Building on these findings, we are establishing a new, on-farm experiment to evaluate whether AMP grazing of overwintering cover crops within row crop rotations can produce similar benefits for building stable SOC fractions that could support climate change mitigation goals.

### INCREASING MINERAL AND PARTICULATE ORGANIC CARBON ACROSS A GRADIENT OF REGENERATIVE MANAGEMENT

K. ESQUIVEL<sup>1</sup>, T. BOWLES<sup>1</sup>, H. WATERHOUSE<sup>2</sup>, K. DASTOGEER<sup>1</sup>

<sup>1</sup> Dept of Environmental Science, Policy, and Management, UC Berkeley, Berkeley, USA

<sup>2</sup> Dept of Environmental Studies, UC Santa Cruz, Santa Cruz, USA

Increasing soil organic matter and soil health has been a long standing goal of regenerative and agroecological farming methods. Practices like cover cropping and organic amendments are recognized for their potential to increase soil organic carbon and produce many co-benefits including increased water and nutrient retention. However, the capacity for carbon storage in soils varies greatly depending on local edaphic and climatic conditions, and the form of the soil carbon itself. A substantial body of research has investigated how so-called 'soil health' or 'regenerative' management affects soil carbon, often conducted at research station-based trials. While such controlled trials are essential, how multiple management strategies interact with inherent soil conditions to modify carbon fractions, mineral versus particulate, is less resolved. This gap is a critical area needed to better understand how farmers can best manage their lands for soil health and climate mitigation.

Using soil samples from 28 organic fields in the California Central Coast alongside detailed management and soil biological data, we assess how the variable adoption of soil health practices (crop rotation and diversity, cover cropping, reduced tillage, and organic amendments) influence the soil carbon fractions on lettuce farms spanning a range of edaphic conditions in our focal region. Additionally, we hone in on what practices have a particularly strong influence on the carbon stored in mineral versus particulate fractions. We demonstrate that cover cropping, continuous plant cover, and reduced disturbance may be important in driving carbon stored in both particulate and mineral fractions, while crop diversity enhances particulate organic matter.

Despite the increasing focus on microbial contributions to the mineral fraction, we find that our metrics of soil biology do not influence mineral-associated organic carbon, indicating that non-biological processes may also be crucial for increasing mineral-associated carbon.

## 4. Soil health in achieving the Sustainable Development Goals 4.22 133580 - Sustainable grassland management for healthy soils and vice versa

### INFLUENCE OF SOIL ACIDITY AND EXCHANGEABLE AL ON THE GROWTH OF TWO FORAGE LEGUMES: LOTUS PEDUNCULATUS AND LUPINUS POLYPHYLLUS

L. BELL, J. MOIR, A. BLACK

Lincoln University. Faculty of Agriculture and Life Sciences, LINCOLN, NEW ZEALAND

Soil acidity and associated Al toxicity limit the growth of forage legumes in high country grasslands of New Zealand (NZ). Forage legume species that tolerate soil acidity and Al toxicity can support sustainable grassland production through increased yields and N fixation. Two species, Lotus pedunculatus (Lotus) and Lupinus polyphyllus (Lupin), have persisted in low-pH soils at agronomic trial sites and commercial farms across the NZ high country. Our objective was to examine how these species respond to soil acidity and exchangeable Al.

At Lincoln University, NZ, Lotus and Lupin were sown in 20-cm tall, 1.2 L pots of acidic high country soil to which was added 0.1 g P/L, 0.9 g S/L, 0.4 g K/L, and either 4.5 or 6.7 g lime/L in either the full pot, top half (0-9 cm), or bottom half (9-18 cm), across six randomised blocks in a glasshouse. Soil pH was 4.4, 4.9 and 5.4 and Al was 24, 2.5 and 1.5 mg/kg for 0, 4.5 and 6.7 g lime/L. Plants were thinned to one/pot, inoculated with fresh, ground nodules for Lotus and Lupin, and watered to field capacity until harvest on 10-15 May 2023, 16 weeks after sowing. Plants were divided into shoots, roots at 0-9 and 9-18 cm, dried at 65°C for 2 days, then weighed. All plants were nodulated at harvest.

Total plant dry weight (DW) and shoot to root DW ratio were higher and shoot %N was lower for Lotus than Lupin across lime rates and depths (13.2 vs. 2.9 g/plant, 5.3 vs. 1.6 and 2.4 vs. 3.3%,  $p < 0.001$ ). For both legumes, root DW was greater in the 0-9 cm than 9-18 cm horizon across lime rates (1.3 vs. 0.3 g/plant,  $p < 0.001$ ). None of these variables were affected by lime rate.

The results indicated that both Lotus and Lupin are tolerant to soil acidity (pH 4.4-5.4) and associated Al toxicity (1.5-24 mg/kg), highlighting their potential for grasslands with acid soils.

## 4. Soil health in achieving the Sustainable Development Goals 4.22 133580 - Sustainable grassland management for healthy soils and vice versa

### SUSTAINABLE FERTILIZATION: THE POTENTIAL OF ROCKING AS A NUTRITIONAL ALTERNATIVE IN BRACHIARIA CROPS

P. BATISTA PASSOS, W. MOZENA LEANDRO, J. PAULO VILELA CASTRO, C. BROM AKI DE OLIVEIRA, M. PORTO MUNIZ, R. SANTOS RIBEIRO, M. LUCAS DA SILVA, L. CATARINA LOBO DE GODOI

Universidade Federal de Goiás, Escola de Agronomia. Programa de Pós-graduação em Agronomia (PPGA), Goiânia, BRAZIL

Agriculture is renewed every decade, thus prioritizing the preservation of soil quality, without harming its characteristics. Rocking, a technique of adding rock dust, is used to improve soil fertility in a sustainable way by releasing nutrients gradually. The aim of this study was to evaluate a sustainable approach in the planting of traditional forage in Brazil (*Brachiaria decumbens*), using rocking in order to reduce the use of chemical fertilizers. The experiment was carried out in a greenhouse at the School of Agronomy of the Federal University of Goiás (UFG), using an Oxisol with a clayey texture. Two products were used: K6 (biotite rock - 5.89% of K<sub>2</sub>O) and HVB-K (mica schist rock - 3.47% of K<sub>2</sub>O), both registered by the Brazilian Ministry of Agriculture. In addition to the soluble chemical, potassium chloride (KCl) as a reference. A completely randomized design was used, with three replications for each treatment. Treatments consisted of T0 (control), T1 (50% K6 dose), T2 (100% K6 dose), T3 (200% K6 dose), T4 (50% HVB-K dose), T5 (100% HVB-K dose), T6 (200% HVB-K dose), T7 (100% KCl dose). The equations were considered significant at 5% probability by the F test. The green mass result was observed significant differences indicated by the F test (7.19), with a coefficient of variation (CV) of 15.14%. At 100% dosages, T5 (HVB-K) stood out by reaching an average of 209.300 kg ha<sup>-1</sup>, surpassing T2 (K6) which recorded 182.600 kg ha<sup>-1</sup>. In the dry mass analysis, there were significant differences indicated by the F test (4.00), with a CV of 20.28%, and the T5 and T2 treatments showed statistical similarity. It was found that the HVB-K presented superior performance compared to the K6 product. Despite its higher concentration of K<sub>2</sub>O, K6 did not guarantee efficiency in increasing *Brachiaria* biomass. However, both products contribute to the sustainable promotion of local agriculture.

## 4. Soil health in achieving the Sustainable Development Goals 4.22 133580 - Sustainable grassland management for healthy soils and vice versa

### EFFECT OF LITTER AND SOIL ORGANIC MATTER CHEMISTRY ON SOIL C, N DYNAMICS OF ALPINE GRASSLAND ECOSYSTEM IN THE QINGHAI-TIBETAN PLATEAU

X. LU <sup>1</sup>, Y. CHEN <sup>2</sup>, Y. HU <sup>1</sup>, Z. WANG <sup>1</sup>

<sup>1</sup> Institute of Mountain Hazards and Environment, Chinese Academy of Sciences, Chengdu, CHINA

<sup>2</sup> Zhejiang A & F University, Hangzhou, CHINA

Plant litter and soil organic matter can influence many fundamental ecosystem functions during decomposition. However, the mechanism of litter and soil organic matter chemistry effects on belowground ecological processes remains unclear, especially with regard to soil C and the N cycle in alpine ecosystems. Here we employed a combination of field survey sampling and incubation experiment to examine the influence of litter chemical diversity and soil organic matter chemical compositions on soil carbon and nitrogen transformation dynamics and greenhouse gas emissions of alpine grassland ecosystem in the Qinghai-Tibetan Plateau. Litter mixing frequently had non-additive effects on litter decomposition which showed more antagonistic effects than synergistic effects, especially in the very early stage of decomposition. Litter chemical traits and climatic factors affected the direction and magnitude of the non-additive effects. Litter treatments significantly enhanced CO<sub>2</sub> and N<sub>2</sub>O emissions and decreased CH<sub>4</sub> immobilization in general; soil organic C, total N, water soluble organic C, water soluble organic N, microbial biomass C, microbial biomass N, and urease activity were also enhanced, while soil total inorganic N was decreased by litter treatments. We calculated six chemical diversity indices, and found litter chemical diversity correlated with the strength of litter mixing effect on soil C and N and the incubation time is also an important factor in understanding the litter-mixing effects. Soil organic matter of five types of alpine grassland ecosystems at the molecular level was dominated by N-compounds (~32.47–51.76%), polysaccharides (~10.67–20.42%), and fatty acids (~7.03–20.33%) in the different alpine grasslands. The most abundant compounds in Soil organic matter were D-alanine (10.06–20.77%), 9-octadecenamide, (Z) (4.43–9.68%), and 13-docosenamide (1.52–14.76%) based on pyrolysis gas chromatography/mass spectrometry (Py-GC/MS). Correlation analysis showed that the N-compound abundance was negatively correlated with nitrate reductase. Polysaccharides were positively correlated with activity levels of invertase and cellulase. Fatty acids were positively correlated with polyphenol oxidase activity and negatively correlated with alkaline phosphatase activity.

### EVALUATING EFFECT OF PHYSICAL AND CHEMICAL CONTROL METHODS OF PTERIDIUM AQUILINUM (BRACKEN FERN) ON SOIL CHEMISTRY ON MT MULANJE AND NYIKA PLATEAU

I.J. TAULO

Forestry Research Institute of Malawi, Zomba, MALAWI

Mountain soils play a crucial role in mitigating climate change through carbon sequestration, regulation of water and carbon cycles. However, they are susceptible to invasive plants, particularly bracken fern (*Pteridium aquilinum*), which have impacts on ecosystem processes and soil communities, causing economic consequences and altering biodiversity. *P. aquilinum* is considered a worldwide invasive. In Malawi, *P. aquilinum* is found on Mt Mulanje and Nyika Plateau. There is currently limited understanding of how current control methods alter soil properties. This study aimed to evaluate the effects of physical and chemical control methods of *P. aquilinum* on soil chemistry on Mt Mulanje and Nyika Plateau. The four years study, investigated how chemical control treatments such as Forester, Eco-Imazypyr, & Lime application, and physical control methods including Mowing, and slashing/cutting can affect soil pH, SOC, exchangeable Ca & Mg, available P, total N and C:N ratio in the invaded areas dominated by *P. aquilinum*.

Two experimental plots were established at each site, and treatments were randomly assigned to plots. At least five soil samples were randomly collected before and after treatments from each quadrant at a depth of 0.15m for analysis in which selected chemical properties were determined. Soil data was subjected to statistical analysis (one way ANOVA) using Minitab 18.0 to determine the effects of the treatments on the soil chemistry. The results indicated significant differences ( $P < 0.05$ ) in soil pH and organic carbon levels after the treatments, with lime treatment displaying the highest (14.46%) pH increase and Forester indicating the highest (64.4%) SOC increase and total N in the soil. However, there were no significant differences in exchangeable calcium, magnesium and C: N ratio for both physical and chemical methods. As all treatments had significantly increased available P in the soil, physical method including Mowing had significantly increased (52.7%) soil organic carbon.

The study concluded that both physical and chemical methods, such as Forester can positively affect soil chemistry in invaded areas.

<sup>2</sup> Department of Animal Production, Facultad de Agronomía, Universidad de Concepción, Chillán, CHILE

<sup>3</sup> Department of Animal Science, Facultad de Ciencias Veterinarias, Universidad de Concepción, Chillán, CHILE

The intensive milk production system in Chile generates a large amount of organic waste from milking parlors on a daily basis, and it is inadequate storage and/or inadequate management has a negative impact on the environment. Incorporating organic matter has favorable effects on the physical properties of soils. The objective of this study was to investigate the physical properties of an Andisol soil treated with twelve years of slurry applications. For this purpose, soil physical quality indicators were evaluated and the results were interpreted with the soil physical quality index. A completely randomized experimental design was used, with six treatments (2, 4, 6, 8, 10 and 12 years of slurry application) plus a control (without slurry application) with four replications, the experimental unit corresponded to plots of 200 m \* 200 m. The study was carried out in permanent pastures composed of *Lolium perenne* L. and *Trifolium repens* L., the application rate was 150.000 L ha<sup>-1</sup> year<sup>-1</sup>. Regarding the physical properties of the soil, in the A horizon, the application of slurry increased organic matter up to six years; between the fourth and tenth year, it favored bulk density and total porosity. In both horizons, it favored available water capacity in the plots that received eight years of application. The organic matter present in the A horizon was positively correlated with the soil porosity and available water capacity.

### SOIL MICROBIAL COMMUNITY STRUCTURE UNDER PERENNIAL BIOENERGY CROPS TREATED WITH DIFFERENT NITROGEN FERTILIZATION RATES

S. DANGI, U.M. SAINJU, B.L. ALLEN, R.B. CALDERON

USDA-ARS, Sidney, USA

Perennial bioenergy crops may enhance microbial community structure and soil health due to extensive root system compared to annual crops. However, long-term effect of perennial bioenergy crops receiving different N fertilization rates on microbial community structure is not well defined. We evaluated the 11-year effect of perennial bioenergy crops with various N fertilization rates as well an annual crop with recommended N rate on soil microbial properties in 2019 and 2020 in the US northern Great Plains. Perennial grasses were intermediate wheatgrass, IWG (*Thinopyrum intermedium* [Host] Barkworth and Dewey) and switchgrass, SG (*Panicum virgatum* L.) with N fertilization rates of 0, 28, 56, and 84 kg N ha<sup>-1</sup>, and annual crop was spring wheat, WH (*Triticum aestivum*, L.) with 80 kg N ha<sup>-1</sup>. The total fungal phospholipid fatty acid (PLFA) proportion and fungal/bacterial ratio were significantly lower under annual spring wheat than perennial grass (SG). Increased N fertilization rate linearly increased Gram-positive bacterial PLFA proportions and Gram-positive/Gram-negative bacterial ratio for IWG in 2020, but decreased PLFA proportions of arbuscular mycorrhizal fungi (AMF) for both perennial bioenergy crops in all years. The proportions of AMF neutral lipid fatty acid and Gram-negative bacterial PLFA were greater for SG than IWG, but actinomycetes and Gram-positive/Gram-negative bacterial ratio were greater for IWG. Microbial community structure varied with perennial bioenergy crops, N fertilization rates, and perennial vs. annual crop. This study showed how perennial crops impact soil biological health and how these differ from annual crops.

**Keywords:** Arbuscular Mycorrhizal Fungi, Intermediate wheatgrass, Switchgrass, Spring wheat, PLFA

## 4. Soil health in achieving the Sustainable Development Goals 4.23 133583 - Soil carbon sequestration and land use change

### ADAPTATION AND MITIGATION OF AGRO-ZOOTECNICAL ECOSYSTEMS TO CLIMATE CHANGE

S. DONI<sup>1</sup>, E. PERUZZI<sup>1-2</sup>, A. SCARTAZZA<sup>1-2</sup>, C. MACCI<sup>1-2</sup>, F. VANNUCCHI<sup>1-2</sup>, I. ROSELLINI<sup>1</sup>, M. SCATENA<sup>1</sup>, G. MASCIANDARO<sup>1-2</sup>

<sup>1</sup> IRET-CNR, Pisa, ITALY

<sup>2</sup> NBFC, Palermo, ITALY

The protection, restoration, and management of natural and modified ecosystems have the potential to address the pressing issues related to climate change and ecosystem degradation.

The improvement of the agro-zootecnical land management is a priority for reducing greenhouse gas emission and sequester carbon, thereby limiting global warming. In addition to climate mitigation benefits, the management of agro-zootecnical lands can also affect climate resilience and adaptation, biodiversity conservation, and socio-economic and health conditions.

In this framework, the present contribution aims to evaluate the pressure induced by agro-zootecnical activities on soil ability to provide ecosystem services, with particular attention to carbon sequestration and nutrient cycles.

Sampling campaigns have been carried out from 2019 to 2023 in different natural and managed areas (forests, grasslands, agricultural and pasture soils) of the Regional Park of Migliarino, San Rossore, Massaciuccoli (Pisa, Italy).

The results highlighted a good content of organic matter (>2%) and nutrients (nitrogen and phosphorus) in all the managed areas, at each sampling time, comparable to those of the natural soils. However, the samples taken in the agro-zootecnical areas showed a greater vulnerability, as evidenced by the decrease over time in organic matter, including the stabilized one (humic substances), which may be linked to the grazing land use and to the uncontrolled presence of wild animals in the fallow areas.

This study provided important information to adequately plan the agro-zootecnical activities (timing, type and quantity of fertilizers, crop rotations, soil tillage, animal density and grazing period) to: 1. increase carbon sequestration, 2. reduce greenhouse gas emissions, 3. protect biodiversity, 4. preserve the physical-chemical-biological soil fertility, and 5. combine the sustainability objectives of agro-zootecnical systems with those of competitiveness, sustainability, and resilience to climate change.

### FROM FOREST TO VINEYARD: EXPLORING CARBON STOCK AND N<sub>2</sub>O EMISSIONS IN A LAND USE CHANGE CHRONOSEQUENCE

A.G. CERVERA MATA, M.A. SÁNCHEZ-MONEDERO, M.L. CAYUELA

CEBAS-CSIC - Department of Soil and Water Conservation and Organic Waste Management, Murcia, SPAIN

Over the past six decades, one-third of the world's territory has been affected by changes in land use mainly originated by agricultural practices. For instance, in Spain, large areas once covered by forests have been replaced by land for cereal cultivation. These activities result in a loss of soil carbon stocks and an increase in greenhouse gas (GHG) emissions. Bosque de Matasnos (Spain) is an estate winery where the conversion from forest to conventional cereal crops occurred 60 years ago, and the transition from cereal crops to organic vineyards took place 20 years ago. Therefore, in this site, three different land uses currently coexist: original forest, traditional cereal crops, and organically managed vineyards. As part of the LIFE-CLIMAWIN Project, the main objective of this study is to demonstrate the mitigation potential of land use change (shifting from cereal-based systems to more sustainable ones, such as organically managed vineyards), using the native forest as a reference. For this purpose, soil GHG emissions (CO<sub>2</sub>, N<sub>2</sub>O and CH<sub>4</sub>) and soil organic carbon stocks are being measured across the three land uses over a period of 2 years. In addition, general soil parameters relevant for soil fertility (e.g., pH, soil texture, carbonate content, available water content, nitrogen content) are also measured. This study presents initial findings regarding changes in carbon stocks in the three sites, showcasing the potential for reversing prior soil C losses through the adoption of regenerative soil management practices such as crop-livestock integration, where organic residues are returned to soil. Preliminary data on N<sub>2</sub>O emissions registered in the three studied sites are also presented.

<sup>5</sup> Agricultural Research, Ltd., Department of Agronomy, Troubsko, CZECH REPUBLIC

Studies on soil organic matter have always been important for soil environmental characterization. Soil potential to sequester or release organic carbon depends on various factors such as soil type, land use/management, climatic conditions, agrotechnical measures etc. The main aim of this study is to show changes in soil organic carbon (SOC) stocks and their development based on modelling by the RothC model. A valuable data set was received from the Field Experimental Station of Mendel University in Zábčice. The unequal development of SOC sequestration under the Norfolk crop rotation and Monoculture of spring barley (*Hordeum vulgare* L.) was documented during the modelled period of 1972-2100. The RothC model recognizes five active compartments of SOC: DPM – decomposable plant material; RPM – resistant plant material; BIO – microbial biomass; HUM – humified organic matter, and inert organic matter (IOM). Each compartment undergoes a different rate of decomposition and through a first-order process was characterized by a unique rate. Two different management scenarios (Norfolk and Monoculture) and three climatic scenarios (MPI, MRI, CMSS) were modelled. The findings revealed that SOC stocks were primarily impacted by inputs of plant residues and the application of exogenous organic materials. The prediction until 2100 indicated a declining trend in SOC stocks under the monoculture management. Moreover, the outcomes underscored that the straw incorporation and intercrops can optimise the sustainability of SOC stock and grain yield of spring barley. Results also showed that SOC stock at the end of the 20th century was approximately 66 t/ha and moderate SOC sequestration (0.09 t/ha/year) was achieved.

### FOREST-SPECIFIC MECHANISMS OF TROPICAL SOIL ORGANIC CARBON PRESERVATION UNDER PHOSPHORUS ENRICHMENT

Y. LI, Z. LIU

South China Botanical Garden, Chinese Academy of Sciences, Guangzhou, CHINA

Tropical forests are sensitive to atmospheric nutrient deposition, the variation of soil organic carbon (SOC) preserving mechanism between the monoculture and the multispecies forest remains to be explored. To reveal the forest-specific properties of microbial composition and metabolism mediating biochemical selectivity for SOC preservation in response to nutrient deposition, we selected a monoculture (Acacia plantation) and a multispecies forest both with long-term (>10 a) addition of phosphorus (P) fertilizers in subtropical regions. In both wet and dry seasons, we measured SOC compounds including specific fingerprints of plant- and microbial-derived C, followed with soil abiotic and biotic properties.

We found that fungal necromass carbon was significantly decreased with P addition in both forests, but due to divergent microbial nutrient acquisition. Site-specific responses of plant substrates, microbial community composition and enzymatic activity to nutrient addition occurred between the Acacia plantation and the multispecies forest. The response of SOC preservation to P availability in the Acacia plantation was likely to be regulated by lignin oxidation and its microbial community composition; meanwhile, plant community composition might be shifted by P addition in the multispecies forest, thus plant substrate-mediated enzyme activities contributed to altering plant- and microbial-derived C in response to P availability. Tight linkages existed between mineral associated C fraction and biotic C compounds in the multispecies forest, suggesting that SOC preserved by biochemical selection could be rather susceptible to chronic P enrichment in this type of forest. These findings provide valuable insights into implications for revealing the biotic mechanisms of SOC preservation in tropical forests and offer guidance for assisting reforestation planning in the context of future nutrient application.

## 4. Soil health in achieving the Sustainable Development Goals 4.23 133583 - Soil carbon sequestration and land use change

### SOIL ORGANIC CARBON IN CHERNOZEM UNDER DIFFERENT AGRICULTURAL PRODUCTION SYSTEMS IN THE PROVINCE OF VOJVODINA, SERBIA

M. STRBAC, M. MANOJLOVIC, R. CABILOVSKI, K. PETKOVIC, D. KOVACEVIC, M. VIJUC

Faculty of Agriculture, University of Novi Sad, NOVI SAD, SERBIA

The multiple and irreplaceable role of soil organic matter and its major constituent soil organic carbon (SOC), is well known, due to their influence on important physical, chemical, and biological soil properties. Land use management affects the SOC and its loss leads to soil degradation and emission of CO<sub>2</sub> from the soil. This study aimed to determine the concentration and stock of SOC in organic (ORG) and conventional (CONV) production systems and to compare them to permanent pastures (PAST).

Chernozem samples (in total 72) were collected from 9 localities in Vojvodina province, Serbia, from depths 0-25 and 25-50 cm. At each site, soil samples were taken from plots under ORG, CONV, and PAST. Soil physico-chemical properties were determined. The stock of SOC (t ha<sup>-1</sup>) was calculated based on the measured SOC concentration, bulk density, and soil depth.

PAST had a significantly higher SOC concentration ( $25.75 \pm 6.38$  g kg<sup>-1</sup> soil) concerning both production systems (ORG  $17.94 \pm 3.27$  and CONV  $18.09 \pm 2.92$ ), in the surface soil. The estimated SOC stock was in the same order as SOC concentration; PAST ( $81.41 \pm 14.20$  t ha<sup>-1</sup>) > CONV ( $61.34 \pm 9.85$ ) = ORG ( $58.82 \pm 11.16$ ). In the 25-50 cm soil layer, PAST SOC concentration ( $18.79 \pm 3.45$ ) and SOC stock ( $65.47 \pm 10.88$ ) were significantly higher compared to the CONV system ( $15.04 \pm 2.89$  and  $52.52 \pm 9.98$ , respectively), and there were no differences between ORG and CONV systems. In soil layer 0-50 cm, the total SOC stock was in order: PAST ( $148.59 \pm 25.38$ ) > ORG ( $113.81 \pm 18.18$ ) = CONV ( $113.92 \pm 18.94$ ). The greatest potential of PAST to store SOC is shown. No significant differences between SOC parameters in ORG and CONV systems indicate that for the improvements of these parameters longer period is needed. However, the positive effects of ORG production on studied plots in the subsurface soil were noticed.

Land use change has a significant impact on soil aggregation and the dynamics of soil carbon. This study aims to examine the effects of converting land use from grassland to cropland on soil organic carbon and soil aggregate stability at the Pontotoc Ridge-Flatwoods Branch Experiment Station in Pontotoc County, Southeast USA. Soil samples were collected from natural grassland and cropland planted with cereal rye (*Secale cereale* L.) at two depths (0-5 cm and 5-10 cm) for measuring soil bulk density, soil aggregate size distribution and stability, as well as soil organic carbon storage. The results showed that soil organic carbon content and storage at 0-5 cm depth increased by 6% and 9%, respectively, after the land use change. In the cropland, the proportion of > 2 mm aggregates, the mean weight diameter (MWD), and geometric mean diameter (GMD) increased by 55%-901%, 43%-151%, and 58%-72%, respectively, while the fractal dimension (FD) decreased by 12%, at depths of 0-5 cm and 5-10 cm, as compared to the corresponding values in the grassland. Collectively, our results underscore the increase in soil organic carbon storage and the stability of soil aggregates resulting from the conversion of land from grassland to cropland, suggesting that planting crops such as cereal rye could serve as an effective method for augmenting carbon input into the soil within agricultural ecosystems. The findings of this study provide novel insights into the alterations in soil aggregation and the potential for soil carbon sequestration following land use changes.

### INFLUENCE OF AGRICULTURE ON SOIL PROPERTIES IN CENTRAL CHILE

B. CÁRCAMO, O. SALAZAR, M. PFEIFFER

Universidad de Chile- Departamento de Ingeniería y Suelos, Santiago, Chile., Santiago, CHILE

Soil chemical and physical properties, such as carbonate content ( $\text{CO}_3^{2-}$ ), pH, electric conductivity, bulk density, among others, can be modified depending on agricultural practices used, e.g. the effect of irrigation water and fertilizer application on the soil. The overall objective of this study is to evaluate the effect of irrigation water from Maipo river -of high hardness-, on the chemical properties of agricultural soils (vineyard) and compare the effect on nonagricultural soils (forest of native vegetation) in an agricultural property of the Santiago basin, Chile (Csb Köppen climate). This study consisted of the definition of six areas according to: the soil parent material (propylitic tuffs, calcareous sedimentary rocks, tuffs, and green lavas), geomorphological position (foothills), and type of use (agricultural, flora conservation). Samples were taken at different depths (maximum of 2.65 m). It was found that soils located in vineyards presented a greater percentage variation of chemical properties comparing surface vs. deep averages, due to agricultural intervention. In the case of native vegetation, properties remained relatively stable along the soil profile. However, comparing both land uses, in most cases the measurements did not show statistically significant differences. In contrast, the presence of  $\text{CaCO}_3$  in values  $>1.5\%$  occurred in the sectors with vineyards at depths between 1.20 and 2.10 m. The  $\text{CaCO}_3$  formation occurred exclusively in soils parent materials of propylitic tuffs and calcareous sedimentary rocks, nevertheless, the latter had the highest  $\text{CaCO}_3$  values ( $>3\%$ ) compared to other parent materials. These soils have a high pH, with a high load of exchangeable cations, specifically calcium, very fine textures, and high bulk densities. In summary, the presence of  $\text{CaCO}_3$  was observed in soils intervened by agricultural activity, mainly influenced by irrigation water. Also, the origin of the parent material influenced the abundance of  $\text{CaCO}_3$ .

### EXPLORING THE ROLE OF DEEP ROOTING ABILITY ON SOIL CARBON ACCUMULATION IN PASTURE-RICE ROTATION SYSTEMS IN A VERTISOL

M MAYORGA COBOS, L RODRÍGUEZ, J ARIAS, P LOZANO, M DA SILVA, C COSTA, M F ALVAREZ, M C REBOLLEDO, C HERRERA, L M HERNÁNDEZ, R JAUREGUI, J ARANGO, I RAO, J. A. CARDOSO

International Center for Tropical Agriculture, Palmira, COLOMBIA

The pasture-crop rotation is an agricultural practice performed on the same land area to obtain multiple benefits, such as improved crop yield, enhanced soil quality, environmental sustainability, and economic profitability. *Urochloa humidicola* forage grasses are a promising option for their use in rotational systems, given their potential to develop deep and vigorous root systems which have been associated with increased accumulation of soil organic carbon (SOC) and their capacity for high biological nitrification inhibition (BNI). The rotation system with improved rice (*Oryza sativa*) genotypes with deep root systems might benefit soil health, from increased SOC, and BNI, reducing nitrogen (N) losses and improving fertilizer use efficiency. The objective of the present study is to evaluate the effect of a pasture-rice rotation compared to conventional management on SOC storage in a 4-year field trial. The field trial was established at the end of 2022 at the Alliance Bioversity International & CIAT Campus in Palmira, Colombia and is comprised of eight treatments organized in a randomized complete block design with management structure. Treatments include permanent plots with two rice genotypes (HL23057, Fedearroz 60), two *U. humidicola* genotypes (Bh08-1149, CIAT679), being the conventional management, and four rice-pasture rotations combining the four genotypes. The trial will annually record root biomass, roots C and N content, and SOC content in topsoil and subsoil layers down to 100 cm depth. The soil is classified as a Vertisol, presented clayey texture (39.63 - 73.81% clay), with SOC content of 3.95 - 21.96 g/kg, and pH of 7.4 - 8.7, across different soil layers. Preliminary results after one year of trial establishment showed that pastures have greater root biomass, root C content and C:N ratio than rice genotypes. These preliminary findings suggest that the use of pasture-rice rotation management can result in greater accumulation of SOC than conventional crop management. Research is in progress to test this hypothesis.

### PLOW ACCELERATES TO DECOMPOSE THE BURIED OLD HUMUS IN VOLCANIC ASH SOIL?

C. HAYAKAWA <sup>1</sup>, H. YAMANAKA <sup>1</sup>, H. UCHIDA <sup>1</sup>, K. FUJII <sup>2</sup>, H. HIRAI <sup>1</sup>, T. KOSAKI <sup>3</sup>

<sup>2</sup> Forestry and Forest Products Research Institute, Ibaraki, JAPAN

<sup>3</sup> Aichi University, Aichi, JAPAN

Over ten thousand years, soils have been formed through events of volcanic ash deposition in Tochigi, Japan. The soil organic matter (SOM) in the past surface layer has been buried in the deeper soil. The buried humic horizons serve as a large carbon (C) reservoir. When the buried humic horizons are exposed to the surface by deep plowing and bottom plow tillage, decomposition of the exposed SOM can be accelerated through priming effects (PE), due to the increased supply of substances from fresh plant litter inputs and microbial activities. To test this, we examined the effects of (1) plow depth and (2) plow strength on the buried humus decomposition through PE.

Soil samples were collected from the volcanic soil profiles in forest site and adjacent arable sites in Tochigi, Japan. To trap the CO<sub>2</sub> released from soils, the soils were incubated with the vials including NaOH solution in the plastic box sealed tightly after substitution of the head space air to CO<sub>2</sub>-free air. After 4 weeks, trapped whole CO<sub>2</sub> concentrations were determined by titration. The amount of CO<sub>2</sub> released from the buried soil were quantified through analyses of the <sup>13</sup>C abundance and <sup>14</sup>C content of trapped CO<sub>2</sub> by AMS.

Plowing induced the positive PEs in the buried soils with every plow depth. Strong plowing also induced the positive PEs in the buried soils, and the CO<sub>2</sub> amount derived from the buried humus decreased in non-plow plot compared with strong plow plot. These results show that the buried humus in volcanic soil can be accelerated to decompose through PE by plowing. However, in the both incubation studies, the values of <sup>14</sup>C content of CO<sub>2</sub> derived from the buried humus ranged ca. 96 – 98 pMC (30 – 190 yrBP). It was considered that relatively recent humus was decomposed by PE for short incubation, and the old humus may be stored even after plow in the buried humic soils.

<sup>2</sup> University of Sao Paulo, Piracicaba, BRAZIL

<sup>3</sup> University of Peradeniya, Peradeniya, SRI LANKA

Agroforestry has been identified as a partial solution to capture atmospheric carbon (C) and store it in the soil and trees for extended periods. The first objective of this study was to quantify soil C concentrations and stocks under tree buffer (TB), grass buffer (GB), grass waterways (WW), and crop field (CS, corn-(*Zea mays* L.)-soybean (*Glycine max* (L.) rotation). The second objective was to evaluate above-ground C stored in trees. Two watersheds were established in 1990 by installing GBs at 22-36-m spacing. Pin oak (*Quercus palustris* Muenchh.), swamp white oak (*Q. bicolor* Willd.), and bur oak (*Q. macrocarpa* Michx.) trees were planted at 3-m spacing on GBs of the TB watershed. Upper 50-cm soils were sampled using a bulk density sampler and lower 50-cm soil was collected by a Giddings probe. Growth of pin, swamp white, and bur oak were evaluated for 24 years in the TB watershed. Greater impacts of WW ( $113.5 \pm 12.9$  Mg ha<sup>-1</sup>), TB ( $106 \pm 14.5$  Mg ha<sup>-1</sup>), and GB ( $102.4 \pm 11.6$  Mg ha<sup>-1</sup>) were observed compared to CS ( $90.9 \pm 10.2$  Mg ha<sup>-1</sup>). Soil C with 10% TB and GB buffer areas within CS were 91.6 and 91.2 Mg ha<sup>-1</sup> compared to 90 Mg ha<sup>-1</sup> by CS alone. Soil C stocks in 2023 for 0-10-cm were +0.63, +1.06, +1.63, and +1.37% greater in CS GB, WW, and TB, than pre-treatment. Mean heights were 11.9-, 9.7-, and 8.4-m for pin, swamp white and bur oak trees. Pin oak recorded the largest above-ground biomass (483 kg tree<sup>-1</sup>) and bur oak had the lowest (130 kg tree<sup>-1</sup>). With the 3-species composition, tree biomass and carbon accumulation in a 24-year period were 22,613 and 10,854 kg ha<sup>-1</sup>. All three species appear to be suitable for watershed protection while pin oak showed promising growth and greater accumulation of biomass and carbon. The study showed long-term benefits of agroforestry alley cropping on soil carbon sequestration and C storage in tree biomass.

### MODELLING CARBON SEQUESTRATION POTENTIAL OF SOILS OF GEORGIA

G. GHAMBASHIDZE <sup>1</sup>, Z. CHANKSELIANI <sup>1</sup>, G. ORMOTSADZE <sup>1</sup>, T. JOLOKHAVA <sup>1</sup>, N. KENTCHIASHVILI <sup>1</sup>, G. ZARDIASHVILI <sup>1</sup>, G. GVENTSADZE <sup>1</sup>, E. SANADZE <sup>2</sup>

<sup>1</sup> Scientific-Research Centre of Agriculture, Soil Fertility Research Service, TBILISI, GEORGIA

<sup>2</sup> Ministry of Environmental Protection and Agriculture of Georgia, Department of Hydro-melioration and Land Management, TBILISI, GEORGIA

The study aimed to estimate soil organic carbon sequestration potential of soils on agricultural lands in Georgia under different sustainable soil management practices. Soil carbon sequestration potential is calculated using an updated version of the Rothamsted Carbon Model (RothC) for the period 2020-2040. Modelling was carried out according to 4 different scenarios: 1) maintaining the current conditions unchanged – business as usual scenario (BAU); 2) SSM-1 involves increasing the amount of organic matter in the soil by 5% through sustainable soil management; 3) SSM-2 involves increasing the input of organic matter to the soil by 10% through sustainable soil management; 4) SSM-3 involves increasing the input of organic matter to the soil by 20% through sustainable soil management. According to the results, the soils distributed in the humid subtropical zone of Western Georgia have a high carbon accumulation potential. In addition, in case of SSM-1 scenario across the country, it is possible to sequester 0.3 million tons of organic carbon in the soils used for agricultural production, which is equivalent to 63% of the total amount of greenhouse gases released into the atmosphere from the agricultural sector of Georgia, contributing about 20% from total GHG emissions of the country.

<sup>3</sup> Genomic Medicine Research Group, School of Biomedical Sciences, Ulster University, Coleraine, UNITED KINGDOM

This work contributes to the largest baseline soil sampling project ever undertaken as part of the £45M UK government funded Soil Nutrient Health Scheme (SNHS) in Northern Ireland (NI). Investigation of the extracellular enzyme activity and soil microstructure in grassland soils across NI is being assessed as a measure of soil health. The project aims to educate farmers on the environmental and financial impacts of various land management practices, this scheme will contribute to the development of policies governing the transition to Net Zero farming in Northern Ireland.

The ongoing assessment of extracellular enzyme activity in grassland soils across Northern Ireland is generating a standard picture of average enzyme activity in soils managed as grassland for either grazing, silage or a combination of grazing and silage. This project correlates the activity of  $\beta$ -1,4-Glucosidase,  $\alpha$ -Glucosidase,  $\beta$ -1,4-N-Acetyl-glucosaminidase and L-leucine aminopeptidase to the total carbon and nitrogen content in the soils, land management practices and pH as well as soil microstructure in a multifactorial assessment of soil health properties. This continuing work has started to identify trends in enzyme activity which correlate to total carbon and nitrogen content.

An innovative approach to assessment of soil microstructure in its natural state has been developed during this project by the use of low-vacuum scanning electron microscopy. Notable differences in soil composition between different soil types have been identified with the aim to compare this to other measures of soil health in an assessment of how beneficial soil microstructure can be in predicting other measurable soil health properties.

When complete, this vast interdisciplinary project aims to educate farmers on important issues such as sequestration of carbon in soil and loss of nutrients through surface runoff into bodies of water as a matter of environmental importance.

<sup>4</sup> Johann Friedrich Blumenbach Institute of Zoology and Anthropology, University of Göttingen, Göttingen, GERMANY

The impacts of urbanization on aboveground biodiversity are well studied, and its impact on soil microorganisms are also receiving increased attention. However, the impact of urbanization on soil protists are hardly investigated. Here, we studied how urbanization and distinct urban greenspaces affect protist communities. We used amplicon sequencing of the 18S rRNA gene of samples from five types of urban greenspaces (parks, greenbelts, industrial areas, residential areas and hospital lawns), neighboring natural forests and agricultural ecosystems in Ningbo, China. We found that urban greenspaces harbored higher protist alpha-diversity than forests, while protist beta-diversity increased from agricultural systems to urban greenspaces to forests. Among the studied driving factors, bacterial community of alpha- and beta-diversity best predicted phagotrophic protist alpha- and beta-diversity in urban greenspaces, while differences in alpha- and beta-diversity of phototrophic protists were best explained by soil carbon-to-nitrogen ratio and fungal beta-diversity, respectively. Abiotic factors including total phosphorus and carbon-to-nitrogen ratio best predicted the alpha- and beta-diversity of protist parasites in urban greenspaces. The results revealed that the composition and drivers of protist communities vary between functional groups and urban ecosystems. Overall, our findings contribute to a better understanding of drivers of soil protist communities and indicate that soil protist communities and associated soil functions could be managed in predictable ways in urban greenspaces.

### INTENSIVE LAND-USE PRACTICES ALTER THE SOIL MICROARTHROPOD COMMUNITY

M. ZIZOLFI, L. SANTORUFO, V. MEMOLI, G. SANTINI, G. MAISTO

Department of Biology, University of Naples Federico II, Naples, ITALY

Agricultural soils represent a large extension of terrestrial ecosystems. Intensive land-use practices can enforce pressures on soil structure, leading to erosion and compaction. These changes can impact the diversity and functionality of soil biota. Among them, microarthropods play an important role in matter cycle and in controlling the microbial component of the soil community. The present research aimed to assess whether the intensive land-use practices alter the abiotic soil properties and the microarthropod community in terms of abundance and functionality. In order to achieve the aim, forest and agricultural soils cultivated at kiwi and vineyards were collected and analysed for the main abiotic properties such as pH, water content, and carbon and nitrogen contents. Moreover, the microarthropod community was investigated. Among soil abiotic properties, only carbon content showed differences between the site type with the highest value in forest soil. Higher biodiversity of the microarthropod community was observed in forest soil. The taxonomical indices of the microarthropod community did not statistically differ between forest and agricultural soils. Nevertheless, shifts in the relative abundances of different taxa were observed, as Formicidae that was significantly more abundant in the vineyard soil. In conclusion, the present research highlighted that agricultural practices strongly reduce the carbon content in soil making the environment less suitable for a large biodiversity of microarthropods. An overall stress condition appeared in the agricultural soil, especially where vineyards were planted, with lower complexity of the community. Further investigations need to examine if different land-use practices could generate impacts into the trophic networks.

### THE ROLE OF EARTHWORMS IN GRASSLANDS

E. VÁZQUEZ <sup>1</sup>, J. ARANGO <sup>2</sup>, M. PULLEMAN <sup>2</sup>, N. TEUSCHEROVÁ <sup>3</sup>

<sup>1</sup> Universidad Politécnica de Madrid (UPM), Madrid, SPAIN

<sup>2</sup> Alliance Bioversity-CIAT, Colombia, Cali, COLOMBIA

<sup>3</sup> Czech University of Life Sciences, Prague, CZECH REPUBLIC

Grasslands are among the most important ecosystems for human livelihoods. Besides their irreplaceable role in human food production, grasslands provide a wide range of ecosystem services at different scales, which are often linked to earthworm activity in grasslands. The capacity of earthworms to improve soil physical properties, nutrient availability, plant biomass production, and soil water balance are well known. Specifically, a high earthworm abundance and diversity in grasslands is often related to high soil porosity and water retention, low soil compaction, formation of soil biogenic aggregates with great stability, high availability of nutrients, and accelerated soil organic matter cycling, leading to high plant biomass production. This, in turn, encourages the maintenance of large and diverse earthworm populations in grasslands.

Most of the world's grasslands are managed to sustain livestock production (as opposed to natural grasslands without human intervention). Earthworms are sensitive to agricultural management, which make them vulnerable to inadequate practices in grasslands. Fertilization, grazing management, modification of the plant community composition (i.e. introduction of improved forages, trees or legumes) can all affect earthworm communities in many direct and indirect (and often interrelated) ways. Here in a literature review, we summarize the potential of different grassland management practices and their possible effects on earthworm populations and communities in the context of sustainable management of grasslands.

Based on their importance and high sensitivity to grassland management, we encourage the inclusion of the earthworm communities among the studied factors for the assessment of grassland management practices. Further, we suggest that using earthworms as bioindicators of grassland health status is accessible by farmers and agriculture services. The development of a standardized method of earthworm assessment adapted to different edaphoclimatic conditions and types of grassland management could help to transfer scientific knowledge generated during the last decades to final users and managers of grasslands.

## 4. Soil health in achieving the Sustainable Development Goals 4.25 133607 - Black Soils: their importance for Food Security and Carbon Neutrality

### OCCURRENCE, DISTRIBUTION AND ECOLOGICAL RISK ASSESSMENT OF HERBICIDE RESIDUES IN CROPLAND SOILS FROM THE BLACK SOIL REGION OF NORTHEAST CHINA

W. HU<sup>1</sup>, R. LI<sup>1</sup>, Q. LIU<sup>1</sup>, B. HUANG<sup>1</sup>, Z. JIA<sup>2</sup>, Y. ZHAO<sup>1</sup>

<sup>1</sup> Institute of Soil Science, Chinese Academy of Sciences, Nanjing, CHINA

<sup>2</sup> Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, Changchun, CHINA

The black soil is regarded as a major contributor to the global food basket. However, the extensive application of herbicides over the past few decades has posed a threat to its health. With limited regional studies on herbicide residues in black soil region of China, this study aimed to provide a comprehensive understanding of herbicide residues, their characteristics, and associated ecological risks in soils across various cropland areas across whole region.

A field survey in the study area yielded a list of 58 commonly used herbicides, and 224 topsoil samples were collected for analysis using HPLC-MS/MS and GC-MS/MS. These findings were utilized to assess occurrences and spatial distribution of herbicides, as well as the ecological risks using the Risk Quotient.

Fifty-six herbicides were detected with total herbicide concentrations ranging from 1.01 to 1558.13 ng/g (mean: 227.45). Atrazine, DEA, DIA, trifluralin and butachlor were the most frequently detected herbicides, while DEA, clomazone, nicosulfuron, fomesafen, and mefenacet exhibited the highest concentrations. Despite being less frequently reported in Chinese soils, fomesafen, nicosulfuron, clomazone, and mefenacet were found widely present. The key factors identified to regulate the fate of herbicides were soil chemical properties, amount of herbicides application, and the crop type. It was observed that the predominant herbicides in the lands cultivated with various crops were nicosulfuron, atrazine, DEA and DIA in corn fields; fomesafen, clomazone and metolachor in soybean fields. The soybean soils showed highest herbicide residues, while the soil mineral contents likely adsorbed more herbicides. Although most of the compounds posed a minimal or low ecological risk, atrazine, nicosulfuron and DEA exhibited medium to high potential risks, with high RQmedian and RI values.

This study presents a comprehensive dataset on herbicide residues and ecological risks in the black soil region of China, highlighting the need for mitigation measures. It also serves as a valuable contribution to decision-making processes and technological advancements in herbicide management and risk control at the global scale.

<sup>2</sup> Institute of Soil Science, Chinese Academy of Sciences, Nanjing, CHINA

<sup>3</sup> School of Geography, Nanjing Normal University, Nanjing, CHINA

<sup>4</sup> School of Earth Sciences and Spatial Information Engineering, Hunan University of Science and Technology, Nanjing, CHINA

Mollisols, also known as a type of black soils, are highly fertile soils characterized by a thick, dark surface layer rich in soil organic matter. Mollisols are not only crucial for food security but also serve as a significant carbon pool. To predict the future evolution of these valuable soil resources, it is important to understand when and how they formed. However, due to intensive mixing by animals, plants, and freeze-thaw processes, it is challenging to accurately obtain soil ages using traditional dating methods that rely on undisturbed sedimentation layers. Here, we utilized luminescence, a light-sensitive property of minerals, to address the challenge of soil mixing. We analyzed more than 2,400 luminescence ages of individual K-feldspar grains from a Mollisol profile in northeastern China. The results showed that the upper 80 cm of the soil body is currently mixed, with the mixing intensity being most intense at the soil surface and decreasing with depth. Additionally, we observed evidence of past soil mixing over the past 50,000 years. The intensity of soil mixing increased around 16,400 years ago. We infer that the paleoenvironment was favorable for forming Mollisols since then, which is significantly earlier than previously estimated.

## 4. Soil health in achieving the Sustainable Development Goals 4.25 133607 - Black Soils: their importance for Food Security and Carbon Neutrality

### INFLUENCE OF GULLY EROSION ON HYDRAULIC PROPERTIES OF BLACK SOIL-BASED FARMLAND

Y. HE, Y. GAO, X. LI, J. CHEN, J. YANG, J. CHEN, C. CAI

College of Resources and Environment, Huazhong Agricultural University, Wuhan, CHINA

Gully erosion is a severe form of water erosion worldwide. However, the influence of gully vicinity on the soil hydraulic properties has been poorly studied, hindering the understanding of their effect on crop yields. Therefore, this study hypothesizes that gully vicinity influences farmlands and aims to determine the mechanism of their influence on soil hydraulic properties and crop characteristics. The soil properties from nine gullies in cultivated lands inclined at 1%, 2%, and 3% in three latitudinal regions were determined at the gully edge (EGO) and 50 m further the edge into the farmlands (EG50) at the following gully units: head, mid-upper, mid, mid-lower, and tail. Soil hydraulic properties (bulk density, saturated hydraulic conductivity, and water retention), soil penetration resistance, and soil organic matter were analyzed. The study findings indicate that the gully existence affected the soil properties at diverse range of intensities. The total-available water content, the ratio of more-available water to total-available water content, saturated hydraulic conductivity, and soil organic matter were lower, but the bulk density and soil penetration resistance were higher at EGO compared with those at EG50. The ratio of more-available water to total-available water content in the gully vicinity was considerably lower in our study than in previous studies, indicating gully erosion substantially deteriorated the hydraulic properties. The differences in soil hydraulic properties between EGO and EG50 were more evident in higher latitudinal region and in steeper farmlands. In addition, the lower soil organic matter and higher bulk density probably led to a 3-11% decrease in crop yield at EGO than at EG50. In summary, this study indicates that gully erosion affects farmland not only at its boundaries but also further into its surroundings. Accordingly, managements suited to the hydraulic properties of the gully-surrounded areas may be implemented to maximize the crop yield of farmlands.

## 4. Soil health in achieving the Sustainable Development Goals 4.25 133607 - Black Soils: their importance for Food Security and Carbon Neutrality

STUDY ON THE SOIL FUNCTION EVALUATION AND REGIONALIZATION OF FARMLAND IN HEILONGJIANG PROVINCE, CHINA

K. WU, J.Y. L., Z. F., M. L.

CHINA UNIVERSITY OF GEOSCIENCES, BEIJING, BEIJING, CHINA

In this study, the research framework of Cultivated land soil function evaluation—Restrictive evaluation of soil function—Cultivated land use zoning and optimization was established. Taking Heilongjiang Province as the research area, the farmland soil function was divided into Primary Productivity, Nutrient cycling and provision, Habitat for functional and intrinsic biodiversity, Water regulation and purification, Carbon sequestration, taking 1km × 1km grid as the evaluation unit to carry out refined evaluation of the cultivated land and soil function in 2018 in Heilongjiang Province, using multi factor comprehensive evaluation, geographical detector and other analysis methods to put forward the division scheme and optimization of cultivated land use function The main conclusions are as follows: (1) This paper constructs the overall research framework of farmland soil function evaluation and zoning, the evaluation method system of soil function limitation, and the research idea of farmland utilization function division and optimization. (2) From the results of spatial distribution of soil function comprehensive evaluation, the study area shows the distribution law of high grade in the northeast and low grade in the southwest. (3) From the perspective of spatial distribution, the supply capacity of soil functions in the southwest of the study area is weak, which can not meet the demand of human society for soil functions. On the contrary, the supply capacity of soil functions in the northeast of the study area is strong and in surplus. (4) According to the results of the geographical detector, the main factors affecting the soil function of cultivated land are slope, erosion and salinization sensitivity. The natural environment and ecological security have a more significant impact on the function of cultivated land. (5) Based on the above analysis results, the cultivated land is divided into four areas: grain supply area, ecological agriculture area, balanced development area and weak functional, and the corresponding cultivated land management mode is put forward according to the regional restrictions.

Soil organic carbon (SOC) has significant implications in regulating soil health. Emerging insights emphasize the important role of microbial anabolism in SOC storage by continuously transforming plant fragments into persistent microbial residues. However, knowledge of the sequestration pathway of root versus shoot carbon (C) is under debate. While recent studies have shown that labile shoot residue is disproportionately important for stable SOC accumulation through microbial assimilation, how plant root vs. shoot residue retention impacts microbial-derived C under different soil fertility conditions remains elusive. Here, we conducted a 500-d in situ experiment using black soils with low fertility (LF) and high fertility (HF) amended with maize root or shoot (both stem and leaf) residues. The microbial residues (amino sugar biomarkers) and microbial communities (lipid biomarkers) were analyzed at 60, 90, 150, and 500 d after the amended materials were added. The results showed that shoot residue input facilitated microbial residue accumulation more efficiently than root input before 150 d. However, at the end of the experiment, the treatment containing added root residue accumulated more microbial residues and produced a higher proportion of microbial residue in SOC, compared with shoot treatment. These results provide novel evidence that root residue can also yield SOC efficiently through the organic substrate–microbial anabolism pathway, but it depends on the decomposition period. Moreover, soil fertility plays an important role in regulating the quantity and relative composition of microbial residues. Specifically, crop residue application greatly increased the contribution of microbial residue C to SOC in the LF treatment compared to that in the HF treatment on day 500. Meanwhile, crop residue addition had a more positive effect on fungal residue accumulation in the LF soil, while it facilitated the accumulation of bacterial residue in the HF soil. These findings highlight that crop residue addition (especially root residue) is an effective approach for improving microbial-derived C sequestration in infertile soils.

### EFFECTS OF CONSERVATION TILLAGE ON SOIL ORGANIC CARBON SEQUESTRATION IN BLACK SOIL

Y. ZHANG <sup>1</sup>, A.Z. LIANG <sup>1</sup>, X.J. LI <sup>1</sup>, E. GREGORICH <sup>2</sup>, N. MCLAUGHLIN <sup>2</sup>

<sup>1</sup> Key Laboratory of Mollisols Agroecology, Northeast Institute of Geography and Agroecology, CAS, Changchun, CHINA

<sup>2</sup> Ottawa Research and Development Centre, Agriculture and Agri-Food Canada, Ottawa, CANADA

In Northeast China, conventional tillage practices caused a decline of soil organic carbon (SOC) and degradation of Black soils (Mollisols). Conservation tillage, particularly no tillage (NT), has been suggested to be an effective practice to control soil erosion and increase the SOC. Hence, we established an experiment (since 2001) to evaluate how a combination of different tillage and cropping systems could improve SOC in black soils. The total SOC storage, SOC fractions (physical and chemical), SOC stability were assessed to evaluate the effects of tillage and cropping system. Our results shows that: 1) different tillage and cropping system combinations had different effects on SOC storage; NT combined with continuous maize had the highest SOC storage among all treatments; 2) The effects of tillage on aggregate size and OC concentration mainly occurred in the surface layer (0–5 cm) while the effect of cropping system on aggregate size and OC concentration mainly occurred at deeper depths; 3) NT increased the recalcitrant carbon pool in surface layer showing the critical need for returning crop residues to maintain long-term SOC storage; 4) SOC mineralization (biological stability) appears to be related to the SOC proportion in the light fraction; 5) More than half of the increase in SOC storage due to NT existed as microbial necromass carbon storage under continuous maize which was higher than maize-soybean rotation. Our study shows that in black soils (Northeast China), NT and appropriate cropping systems can not only halt soil degradation caused by poor management but can induce substantial increases in SOC which is beneficial for SOC long-term sequestration.

### INCORPORATING MANURE IN THE NO-TILL SYSTEM IMPROVES SOIL HEALTH AND CROP PRODUCTION OF DEGRADED BLACK SOILS

Z. TIAN, Z. SUN, J. CHEN

Huazhong Agricultural University, WUHAN, CHINA

No-till agriculture can improve soil health, reduce erosion, and benefit the environment. Manure application is also a good way to enhance soil quality and carbon stock. However, direct applying manure to the surface of no-till field may lead to nutrient loss. In this study, we conducted laboratory simulations and field experiments to evaluate the effects of different manure application strategies in the traditional plowing and no-till system on soil health and crop production of degraded black soils. Seven strategies were investigated: traditional plowing (CK), CK + 30 t/ha manure (CKM), No-till (NT), NT + surface application of manure (NTS), NT + application of manure with disk injector (NTD), NT+ application of manure with poultry litter injector (NTP), and NT + application of manure with chisel injector (NTC). The laboratory simulation showed that, compared to CK, NT and CKM decreased or had no effect on soybean production (shoot fresh weight, shoot dry weight, and yield). While the four NT + manure strategies gave higher yields (+15% on average) and shoot dry weight (+16%). NTD performed the best with a yield improvement of 34%. Rainfall simulations showed the five NT treatments had fewer nutrient losses (total nitrogen and phosphorus) than the CK and CKM because of less leaching and runoff. NTS had higher ammonia volatilization than the CKM (+6.2%), but the NTD, NTP, and NTC had no significant difference with the CKM. Besides, NTD improved the soil aggregate stability and had beneficial effect on soil fungi diversity. Field experiments further compared the performance of NTD on corn production and quality of the degraded black soil. The first-year experiment showed that NTD reduced surface runoff, improved soil nutrients and organic matter content, and provided higher corn yields (~10%) than the NT and CK treatments. Thus, incorporating manure in the no-till system could be a promising strategy for improving soil health and crop production of degraded black soils.

### RESPONSE OF SOIL ENZYMATIC ACTIVITY TO PORE STRUCTURE UNDER INVERSION TILLAGE WITH ORGANIC MATERIALS INCORPORATION IN A HAPLIC CHERNOZEM

W. ZOU, X. HAN, C. LIU, X. CHEN

Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, Harbin, CHINA

Soil pore structure affects microbial survival environmental conditions and thus enzyme activity. The mechanisms underlying returning organic materials on soil pore structure and enzymatic activity, however, remain unclear. We therefore conducted a field experiment in 2018 in northeastern China with a chernozem soil and four treatments: CT, conventional tillage; SCT, returning maize straw incorporation with conventional tillage; SIT, returning maize straw incorporation with inversion tillage; SMIT, returning maize straw and organic manure with inversion tillage. We used X-ray computed tomography to analyze the characteristics of pore structure and extracellular enzymatic stoichiometry to evaluate the limiting factors for soil microorganisms. Inversion tillage and organic materials incorporation can alter the micromorphological structure of entire soil layer, leading to the rearrangement of soil particles and nutrients, thereby augmenting the physicochemical properties in subsoil layer. SMIT exhibited a substantial increase in the number of macropores, porosity and fractal dimension, compared to SCT and SIT. This led to a significantly increased in soil enzyme activities of carbon and nitrogen-limited in SMIT, with increases ranging from 11.67% to 40.16% and from 8.81% to 21.43%, respectively ( $P < 0.05$ ). Analysis using structural equation modeling revealed that returning organic material was conducive to the development of soil pore structure, characterized by an increase in macropores and fractal dimension and a decrease in the Euler number, had a positive correlation with soil enzyme activity. This, in turn, led to an alleviation in microbial nitrogen limitation. These results indicate that SMIT could serve as a viable choice in enhancing soil structure and fostering a favorable environment for microbial survival. Moreover, they offer essential insights into the microbial strategies responsible for the breakdown of organic matters in Hapli-Udic Cambisol.

### STRAW RETURN ENHANCES THE PORE MORPHOLOGY AND SIZE DISTRIBUTION MEDIATED BY INCREASED AGGREGATE-ASSOCIATED CARBON AND NITROGEN

X. HAN, W. ZOU, X. CHEN, Y. ZHAO

Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, Harbin, CHINA

The accumulation of soil organic carbon (SOC) and total nitrogen (TN) is easily accomplished by returning crop straw, which strongly affects the formation and pore structure of aggregates, especially in black soil. We returned maize straw at different rates (6000, 9000, 12 000 and 15 000 kg ha<sup>-1</sup>) for nine years to investigate its influence on the SOC and TN contents in SOC fractions of aggregates by combining the size and density fractionation, and their subsequent influence on the pore morphology and size distribution characters through using X-ray micro-computed tomography scanning (CT). The results showed that returning straw significantly increased the contents of C and N in the SOC fractions of aggregates, especially at the rate of return of 12 000 and 15 000 kg ha<sup>-1</sup>, which in turn promoted aggregate formation and stability and then amended pore structure. Pore size >0.100 mm, porosity (>0.002 mm), and morphological characteristics (anisotropy, circularity, connectivity and FD) significantly increased, but the total number of pores significantly decreased ( $P < 0.05$ ). Our results indicated that the amendment of pore morphology and size distribution of soil aggregates was primarily controlled by the increased content of C and N in density fractions of aggregates, rather than in the aggregate sizes. And pore network reconfiguration favored the C and N storage simultaneously.

### THE THICKNESS AND VARIATION RATE OF DRYLAND BLACK SOIL IN NORTHEAST CHINA FROM 1982 TO 2022

L. MA<sup>1</sup>, Z. GAO<sup>1,2</sup>, D. YU<sup>1,2</sup>

<sup>1</sup> State Key Laboratory of Soil and Sustainable Agriculture (Institute of Soil Science, Chinese Academy of Sciences), Nanjing, CHINA

<sup>2</sup> University of Chinese Academy of Sciences, Beijing, CHINA

Clarifying the thickness and variation rate of dryland black soil is important to soil protection and food security. The missing of black soil thickness and the spatial-position inconsistent of sampling sites in different periods hinder the study of thickness and variation rate in Northeast China. In this study, we surveyed the thickness of black soil at 663 sampling sites using a novel method combining shovel and soil auger in 2022 and collected 4379 soil profiles from 1980s. The survey method was validated by comparing with the soil profile-based method. Meanwhile, we also developed a method to convert the thickness of soil genetic layer to that of black soil. Then we built models to predict thickness of black soil based on the sampling data, environment variables, and random forest algorithm. Finally, the thickness and variation rate of dryland black soil in recent 40 years were obtained. The results show that the survey method captured 91% variations of soil profile-based thickness. The thickness converting method from genetic layer the black soil layer captured 80% variations of the survey method. The accuracy of prediction models for thickness of black soil were almost the same in 2022 and 1980s with RMSEs of 26.5 cm and 26.4 cm, respectively. The prediction models tended to be overestimate (underestimate) results when the thickness is lower (higher) than 50 cm in both two periods. The average thicknesses were 43.6 cm and 54.7 cm in 2022 and 1980s, respectively. The thickness of black soil trended to decrease with a rate of 0.28 cm/year. There were differences in decreasing rate of black soil for different soil types and slope positions. The decreasing of thickness in Songnen plain area should be paid attention. This study characterizes the thickness and variation rate of dryland black soil based on large samples and machine learning method and provides technical and data support for black soil protection.

### HYPERSPECTRAL INVERSION AND DIGITAL MAPPING OF SOIL ORGANIC MATTER OF BLACK LAND IN NORTHEAST CHINA

Y. HUANG <sup>1</sup>, Y. GOU <sup>2</sup>, X. LIU <sup>1</sup>, W. ZHOU <sup>1</sup>, H. TANG <sup>1</sup>, Y. LIU <sup>1</sup>

<sup>1</sup> COLLEGE OF LAND SCIENCE AND TECHNOLOGY, CHINA AGRICULTURAL UNIVERSITY, BEIJING, CHINA

<sup>2</sup> BEIJING SHIJI NONGFENG LAND SCIENCE & TECHNOLOGY CO., LTD, BEIJING, CHINA

Soil organic matter is a key indicator of soil quality in Black land. Rapid acquisition of soil organic matter content, clarification of its relationship with environmental factors, and efficient digital mapping are crucial for the protection and utilization of Black soils. The Songliao Plain is located in the northeast region of China, which is a typical concentrated distribution area of Black soils, and is of great significance for ensuring food production in China. This study constructs a hyperspectral fast and accurate inversion method for soil organic matter, systematically revealing the correlation, causal relationship, and geographic dependence between soil organic matter and environmental factors, and exploring the influence of modeling methods and environmental variable quantities on spatial prediction and digital mapping of soil organic matter. The results indicate that: (1) Continuous wavelet transform technology can improve the correlation between soil spectra and soil organic matter content, stable competitive adaptive reweighting sampling algorithm can extract important feature information variables related to soil organic matter, improving modeling efficiency; (2) The annual average temperature is the main controlling factor affecting the spatial distribution of soil organic matter content in the Songliao Plain. Soil factors are also important factors affecting the spatial distribution of organic matter. Climate factors have the strongest impact on soil organic matter. Soil factors have the strongest direct effect on organic matter, with the path coefficient is 0.55; (3) The major direction and the minor direction of soil organic matter variations in Songliao Plain was 56° east by north and 146° east by north, respectively. The scale and location-specific variations in SOM and environmental factors were direction-specific; (4) The random forest model demonstrated the best performance in spatial prediction and digital mapping of soil organic matter. The partial least squares regression model demonstrates the worst performance, and there is a significant underestimation of low value areas.

### BLACK SOILS IN NORTHEAST CHINA BASED ON LAYERED SOIL ATTRIBUTE DATA AND ARTIFICIAL NEURAL NETWORK

J. NIU, H. TANG, Z. HUO, Y. HUANG, Y. LIU

COLLEGE OF LAND SCIENCE AND TECHNOLOGY, CHINA AGRICULTURAL UNIVERSITY, BEIJING, CHINA

The relationship between grain yield and cultivated land soil properties is a pivotal concern in grain production. Traditional grain yield prediction models typically focus on the surface soil layer (0-30cm), overlooking the interaction with deep-layer soils. This study aims to investigate the relationship between soil properties at different depths and grain yield, constructing a model that integrates vertical dimension features. The research utilizes stratified soil attribute data from various counties in the black soils of Northeast China to conduct grain yield prediction analysis. Pearson correlation analysis is employed to examine the relationship between different soil layers and grain yield. Artificial neural networks are utilized for interval prediction, and a multiple regression model is developed to construct a soil vertical dimension grain yield prediction model. The results indicate that: (1) Cation exchange capacity, clay content, organic carbon content, and total nitrogen content are significantly correlated with grain yield, with correlation coefficients of  $r(15-30\text{cm})=-0.516$  ( $p=0.000$ ),  $r(30-60\text{cm})=-0.465$  ( $p=0.001$ ),  $r(15-30\text{cm})=-0.619$  ( $p=0.000$ ),  $r(15-30\text{cm})=-0.573$  ( $p=0.000$ ). (2) The weights of stratified soil properties gradually decrease with increasing soil depth. The 30-60cm soil layer has a significant impact on grain yield formation, likely due to lower disturbance in sub-surface soil, promoting more frequent microbial activity and decomposition. (3) Compared to traditional yield prediction models, the new model's  $R^2$  increased from 0.479 to 0.553, indicating a 15.15% enhancement in the model's explanatory power for grain yield. The transformation of grain yield into interval numbers for computation has strengthened the robustness and prediction accuracy of the forecasting model, possibly due to interval numbers more effectively reflecting the comprehensive impact of factors such as soil, crops, and human activities on grain yield. Considering the vertical dimension of soil can further improve the prediction accuracy of grain yield. In the future, the monitoring and evaluation of deep soil properties should be paid attention to in the protection and management of cultivated land, so as to formulate more effective cultivated land protection measures.

### THE IMPACT OF STOVER MULCH QUANTITY ON SOIL ORGANIC CARBON ACCUMULATION MEDIATED BY MICROBIAL COMMUNITY

Y. YANG

Institute of Applied Ecology, Chinese Academy of Sciences, SHENYANG, CHINA

Stover mulching over no-till soil is regarded as a promising practice to increase soil organic carbon (SOC) in croplands against climate change. Microorganisms play key roles in the dynamics of soil organic matter and nutrient cycling. Microbial necromass is a significant source of SOC stock and unequivocally controlled by the microbial community. Yet, a complete link that spans from agricultural practices to microbial community features, to soil necromass C, and eventually to SOC is poorly understood. Here, we conducted a 10-y corn field experiment with five treatments, which included conventional tillage (CT), no-tillage without stover (NT-0), and no-tillage with low, medium, and high amounts of stover mulching (NT-low, NT-medium, and NT-high) in northeastern China. We investigated the stocks and changes in total SOC and its microbial necromass C along a soil depth down to 40 cm, and we evaluated how SOC dynamics and stabilization processes were associated with microbial community features. We characterized microbial community diversity and structure using 16S rRNA and internal transcribed spacer (ITS) sequencing, and we characterized microbial biomass and necromass using phospholipid fatty acid and amino sugar biomarkers. Compared with conventional tillage, no-tillage with medium and high amounts of stover mulching increased SOC stocks in the upper 0-40 cm of soil by > 0.4 % per year. No-tillage treatments (without and with stover) had almost no effect on the proportion of total microbial necromass C to SOC, but greatly modified the ratio of fungal necromass C to bacterial necromass C, which increased in top layers (0-5 cm) and decreased in deep layers (10-40 cm). SOC was governed mainly by fungal necromass C, which was correlated positively with fungal biomass. Fungal necromass C, not bacterial necromass C, was more closely associated with microbial community composition. Our results suggested that no-tillage with medium stover mulching was the optimal treatment to achieve the best trade-off between stover input and SOC storage.

### HOW GULLY EROSION DAMAGES FARMLANDS AND REDUCES GRAIN YIELD IN TYPICAL MOLLISOL REGION OF NORTHEAST CHINA

F. ZHENG, B. WU, T. ZHAO

Northwest A & F University, YANGLING, SHAANXI, CHINA, CHINA

Gully erosion damages farmlands and reduces grain yield. But at present, how gully erosion reduces arable land and grain yield is still less reported. Thus, this study, taking a typical Mollisol region Keshan County of Heilongjiang province as a case study, applied 0.4 m high-resolution remote sensing images, land use data and statistical yearbook data to extract erosion gullies, investigate farmland area damaged by gullies and address gully erosion impacts on grain yield. The results showed that the total of 3395 erosion gullies was extracted from the study area, in which the number of small erosion gullies (gully surface area is smaller than 0.5 ha), medium erosion gullies (gully surface area is between 0.5 ha and 1.4 ha) and large erosion gullies (gully surface area is larger than 1.4 ha) were 2323, 745 and 327, respectively. And mainly distributed in the western and eastern areas of Keshan county. The ratio of arable land area damaged by erosion gullies to gully surface area was 2.0 to 2.84 times. Moreover, the total farmland area in the study area damaged by all gullies was 4796.65 ha, and the averaged value damaged by each gully erosion was 1.41 ha. The reduction in grain yield by gully erosion was 22239.37 t, including 18950.29 t corn yield and 3289.08 t soybean yields. This study can provide important scientific basis for erosion gully control in Chinese Mollisol region.

### EFFECTS OF TILLAGE ON SOIL PORE CHARACTERISTICS AND FUNCTION IN THE NORTHEAST OF CHINA

J. TAN, W. HAN, Y.L. YI

College of land and environment- Department of Shenyang Agricultural University, Shenyang, CHINA

No tillage is considered to be one of the conservationist management systems due to its environmental and agronomic benefits, and it is being increasingly adopted in northeast China. However, the effects of tillage on soil pore characteristics and its function need to be further studied, which is directly related to the application effect of no tillage in this area. The objective of this study was to investigate how tillage systems (rotary tillage, RT; subsoiling, SS; no tillage with maize straw mulch, NT) affect soil pore characteristics, which in turn affect soil water holding capacity and gas transport function. Undisturbed soil samples were collected from 0-40cm soil layer for X-ray Computed Tomography ( $\mu$ CT) at a resolution of 25 $\mu$ m and measurements of bulk density, soil water retention, air-filled porosity, and relative gas diffusivity. Compared with conventional tillage, SS showed larger total porosity and relative gas diffusivity, while NT showed smaller total porosity and relative gas diffusivity for dry soil. NT increased the available water content of 0-30cm soil depths, and within the water range, the relative gas diffusivity under NT was similar to that of RT and SS. Soil under NT created more irregular pores in 0-30cm soil layer, and the ratio of irregular porosity to regular porosity ( $I_r/R$ ) was significantly higher than that under SS. The correlation analysis results showed that  $I_r/R$  was positively correlated with specific diffusivity at -6kPa matric potential. The results from this study indicate that NT leads to change pore morphology to have positive implications for soil water content and gas transport.

Black Soils are characterized by the dark surface horizons with high carbon content and high natural fertility. They include soils classified as Chernozems, Kastanozems, and Phaeozems in the World Reference Base. Despite their relevance in terms of food production, many concerns persist about the carbon storage potential and risk of degradation of black soils. Notably documented in China, Russia, Kazakhstan, Ukraine, the European Union, and United States and Canada, in the South America, Argentina has the most comprehensive extension and research on black soils. In Brazil they are identified as tropical, anthropic, and midlatitude black soils (FAO, 2022). The midlatitude black soils are located in southern region of Brazil, under the Atlantic Forest and Pampa biomes with a subtropical climate, and they are intensively used for fruit production and cattle farming. This study focuses on carbon stocks in the upper 0.2 m of representative Brazilian subtropical black soils. In some sites under Pampa's gallery forest the carbon stocks range from 90 to 107 Mg ha<sup>-1</sup>, with the areas accessible to cattle showing higher stocks. In natural grasslands the carbon stocks were 74.1 Mg ha<sup>-1</sup> whilst the agroforestry systems in the adjacencies, with 1 and 3 years of management, witnessed carbon losses of 15 and 26 Mg ha<sup>-1</sup>, respectively. Agroforestry is considered a sustainable system, but tillage must be minimized to prevent significant carbon loss. In the Atlantic Forest biome, areas with vineyards of about 80 years exhibited an average carbon stock of 61 Mg ha<sup>-1</sup>, emphasizing the carbon sequestration potential of black soils under this form of agricultural use. Despite their critical role in food production and carbon sequestration, the subtropical black soils in Brazil face threats from erosion and loss of carbon in areas of agriculture and cattle production without conservation practices. Brazilian policies for agriculture must play a pivotal role for mitigation of climate change by safeguarding and enhancing soil carbon stocks.

Brazilian Subtropical Black Soils: carbon stocks and agriculture in the Atlantic Forest and Pampa biomes. Areas of soil sampling.

### PERVASIVE SOIL PHOSPHORUS LOSSES IN TERRESTRIAL ECOSYSTEMS IN CHINA

X. SONG, G. ZHANG

Institute of Soil Science, Chinese Academy of Sciences, Nanjing, CHINA

Future phosphorus (P) shortages could seriously affect terrestrial productivity and food security. We investigated the changes in topsoil available P (AP) and total P (TP) in China's forests, grasslands, paddy fields and upland croplands during the 1980s-2010s based on substantial repeated soil P measurements (63,220 samples, in the 1980s, 2000s and 2010s) and machine learning techniques. Between the 1980s and 2010s, total soil AP stock increased with a small but significant rate of 0.13 kg P ha<sup>-1</sup> yr<sup>-1</sup>, but total soil TP stock declined substantially (4.5 kg P ha<sup>-1</sup> yr<sup>-1</sup>) in the four ecosystems. We quantified the P budgets of soil-plant systems by harmonizing P fluxes from various sources for this period. Matching trends of soil contents over the decades with P budgets and fluxes, we found that the P-surplus in cultivated soils (especially in upland croplands) might be overestimated due to the great soil TP pool compared to fertilization and the substantial soil P losses through plant uptake and water erosion that offset the P additions. Our findings of P-deficit in China raise the alarm on the sustainability of future biomass production (especially in forest), highlight the urgency of P re-cycling in croplands and emphasize the critical role of country-level basic data in guiding sound policies to tackle the global P crises.

### SEASONAL DYNAMICS OF SOIL pH AND N TRANSFORMATION WITH <sup>15</sup>N LABELING FERTILIZATION IN SUBTROPICAL CHINA

J.L. YANG, Y. DONG, G.L. ZHANG

Institute of Soil Science, Chinese Academy of Sciences, Nanjing, CHINA

Nitrogen (N) fertilization-induced soil acidification has received much attention worldwide. Nitrification and soil N mineralization are two key N cycle processes that affect soil acidification, however, the seasonal dynamics of soil pH under their combined influence remains unclear. We studied the seasonal dynamics of soil pH and N transformation using <sup>15</sup>N tracing in field lysimeters with soils developed from different parent materials (Quaternary red clay, sandstone, and basalt). 200 kg N ha<sup>-1</sup> yr<sup>-1</sup> of urea was applied with maize planting. During 7-45 days after fertilization, proton (H<sup>+</sup>) production from nitrification of fertilizer N, nitrate (NO<sub>3</sub><sup>-</sup>) leaching, and plant uptake exceeded H<sup>+</sup> consumption by base cations exchange, resulting in a significant decline of soil pH. When nitrification decreased (after 45 days) due to the exhausted substrate, soil pH rose again. During the fallow period, neutralization by base cations exchange and mineralization of soil organic N (SON) as well as the associated release of base cations offset H<sup>+</sup> production from nitrification of mineralized SON and thereafter led to a sustained rise of soil pH. After the one-year experiment, no significant decrease in soil pH was observed in any of the soils. In subtropical regions, with the changing of N transformation and plant growth, there is an obvious seasonal variation of soil pH after N fertilization. Parent material had little effect on the seasonal variation, which appeared to be controlled by fertilization, environmental factors (temperature and moisture), and plant uptake.

The complexity and dynamism of urban soils complicate analysis of their function and support of ecosystem services. Long-term studies can be a great aid for addressing this complexity allowing for evaluation of how changes are driven by variation in climate and land use and management.

In the Baltimore Ecosystem Study (BES), measurements of soil moisture and temperature, soil:atmosphere fluxes of carbon dioxide, nitrous oxide and methane, soil solution chemistry, and riparian groundwater level and chemistry have been ongoing in urban forests and grasslands since 1998. These studies have been carried out in a watershed context that integrates ecological, physical and social sciences. Watershed input/output budgets for nitrogen have shown surprisingly high retention which has led to detailed analysis of sources and sinks in these watersheds. These long-term studies have shown that urban forests and grasslands have more complex coupled carbon and nitrogen dynamics than previously thought. Urban soils have a high potential to cycle and retain, as well as to lose nitrogen and the balance between retention and loss is a complex function of social and hydrobiogeochemical processes. Basic science research on these processes, and their interactions improves our basic science understanding of soils and can lead to improved management of an important land use/land cover type.

From the Proper Utilization of the Soil to the Preservation of Biodiversity

A Study on Pollinator Insects and Their Vital Role in Sustaining Plant Biodiversity and Ecosystems Health

From Words to Actions: Establishing “Buzz Lines” in Anthropized Areas  
Our “Bee Garden”

Class 3A and 3B, Scientific High School “Ettore Majorana” – Capannori (LU) –  
School Year 2022-2023

### Introduction

A soil in its natural state provides the ecosystem services necessary for its own sustenance. Simultaneously, it is a fragile resource often regarded with insufficient awareness and diminished attention.

Environmental degradation is closely linked to soil degradation.

Our study focused on the significant decline of pollinator insects and the necessity of preserving green areas even within urban territories to provide genuine “ecological corridors” for bees.

The introduction of these spaces could also contribute to an eco-friendlier use of anthropized and degraded soils in cities.

### Our Project

We conceived the idea of implementing a mini- ecological corridor to “turn words into actions” and to raise awareness among other students in the school.

The series of soil seminars provided to us by the Lions association “Antiche Valli Lucchesi” and the reading of the latest ISPRA report (see references) served as stimuli and driving forces to develop our project. To grasp the issues of impoverished soil firsthand, we conducted a series of chemical analyses in the school laboratory of the soil of our school garden, both before and after fertilization with compost produced by us. Subsequently, we researched perennial plants that bloom in summer, a period when bees struggle to forage. We selected a variety of aromatic plants and planted them to create our small “bee garden”.

### A COMPARATIVE EVALUATION OF THE ROLE OF THE ORGANO-MINERAL COLLOIDS AND THE TEXTURE OF THE FINE SOIL ON THE HYDRAULIC PROPERTIES OF COMPOSITE SOILS

B. NASRI<sup>1</sup>, O. FOUCHÉ-GROBLA<sup>1&2</sup>, M. MAKHOUL<sup>1</sup>

The collection and composting of food waste are a common practice for recycling bio-waste for use as a soil amendment. The hydraulic properties of a composite soil (must ensure that its water retention and transfer functions are optimal). The role of organic matter in regulating the soil carbon cycle has largely been studied and demonstrated, the role of soil-absorbing clay-organic complexes, i.e. all the colloids in controlling the main hydraulic properties of the soil: porosity, soil available water and soil hydraulic conductivity, is not known. In this study, the role of clay-organic components in the main hydraulic properties of composite soils has been questioned. Field experimental plots filled with mixtures of mineral waste and food waste compost, has been designed and carried out. Each month, Mini Disc and one BEST in situ infiltration tests are realized to determine the hydrodynamic characteristics of the composite soil. Then, soil samples (disturbed and non-disturbed) are taken per plot et per month to perform a series of classical-called physico-chemical characterization tests essentially including total organic matter (OM) content and granulometry by Laser apparatus. A performance protocol is adapted to draw the particle size distribution curve of fine particles (< 2  $\mu\text{m}$ ) by laser-granulometry analyses in samples containing and not containing organic matter. Interpretation of tests enable to estimate the hydraulic conductivity using the BEST method, to plot the soil retention curve according to physical properties and to deduce the soil's available water content. By assumption, the fraction of fine clay-organic components would be different from one plot to the next, and the main variable over time. In general, organic matter is destroyed before texture analysis. But here; we also carry out a soil texture analysis including OM. Then, by differentiating the two curves (with and without OM) with the laser granulometer, we obtain the size distribution of the OM particles in the complete particle size curve and evaluate its role on the measured hydraulic properties.

<sup>3</sup> National Biodiversity Future Center, Palermo, ITALY

<sup>4</sup> National Research Council of Italy - Institute of Sciences and Technologies for Sustainable Energy and Mobility, Torino, ITALY

The continuous urban development is propelled by social and economic needs, albeit at the expense of the earth's surface due to land consumption. Soil sealing emerges as a detrimental threat, since impermeable materials permanently cover the soil, compromising various soil ecosystem services, including the production function, carbon fixation and storage capacity, regulation of water and gas fluxes, as well as the amelioration of water and air quality. In this context, the two-year project (funded by the European Union - Next Generation EU – PRIN 2022 PNRR) centers on the possibility of reclaiming and repurposing long-sealed soils to restore their functionality and ecosystem services. The primary focus of the research is to establish urban gardens (UGs) in abandoned sealed areas by removing covers, implementing field operations, and applying specific treatments to ensure the growth of seasonal vegetables. The project is carried out in Ancona, a medium-sized city along the Adriatic coast, with a population of 100.500 inhabitants. In accordance with the Municipality, two different public abandoned areas are provided. The main stages are: i) a preliminary assessment of de-sealed soil to evaluate its morphological, physical, chemical, and biological properties and identify dysfunction, threats, and weaknesses; ii) an evaluation of compost characteristics that will be applied to promote plant growth and soil restoration; and iii) monitoring and estimating plant quality, including standard measurements required to guarantee food safety. After each crop cycle, soil characteristics assessed at the beginning of the experiment will be analysed to evaluate the effective restoration of soil capacity. This information will provide scientific guidelines for managing these areas for community UGs. Positive outcomes from the project are anticipated to yield environmental and social benefits, including the restoration and reuse of degraded and unused urban surfaces, recovery of soil functionality after de-sealing, and the establishment of new green areas for citizen use.

<sup>2</sup> INRAE Info&Sols, Orléans

The recent emergence of studies on plastic contamination of terrestrial environments has revealed the presence of microplastics (MP) in a variety of soil types, from the most densely populated areas to the most remote ones. However, the concentrations and chemical natures of MP in soils vary between studies, and only a few ones have focused on this issue in France.

The MICROSOF project aimed to establish the first national reference to French soil contamination by microplastics. Microplastics were analyzed in thirty-three soil samples selected from the French soil quality monitoring network, mostly among agricultural areas but not only. The study collected data on the abundance of microplastics in the [315 - 5000]  $\mu\text{m}$  range, their chemical nature and size, as well as mass abundance estimates and other relevant information. Results demonstrated that 76% of the soil samples contained microplastics, in concentrations ranging from  $< 6.7$  to  $80 \text{ MP.kg}^{-1}$  (dry soil). Most samples from croplands, grasslands and vineyards and orchards were contaminated, whereas only one sample from forest contained MP, suggesting an increased risk of microplastic contamination in soils exposed to agricultural practices. The MP abundances were not statistically different from similar studies, indicating an intermediate level of contamination in French soils. Despite the information collected from farmers about their agricultural practices through intervention reports and surveys, the sources of microplastics in soils remained unclear questioning the transfer and behavior of those contaminants in the environment. Thanks to the support of ADEME, this study gave, for the first time, an overview of soil contamination by microplastics in France, as well as the potential risks. It also advocates for an integration of microplastics analysis on national soil monitoring programs to better apprehend the presence of those compounds in soil and their potential threats to ecosystems and humans.

## 4. Soil health in achieving the Sustainable Development Goals 4.27 133609 - How will we monitor soils in the coming century?

### FIRST GLANCE OF FRENCH SOIL CONTAMINATION BY PESTICIDE RESIDUES AND THE NEED FOR BROAD-SCALE MONITORING

C. FROGER<sup>1</sup>, C. JOLIVET<sup>1</sup>, H. BUDZINSKI<sup>2</sup>, M. PIERDET<sup>2</sup>, G. CARIA<sup>3</sup>, N. SABY<sup>1</sup>, D. ARROUAYS<sup>1</sup>, A. BISPO<sup>1</sup>

<sup>1</sup> INRAE INFO&SOLS, ORLEANS, FRANCE

<sup>2</sup> UNIVERSITE BORDEAUX UMR EPOC, BORDEAUX, FRANCE

<sup>3</sup> INRAE LAS, ARRAS, FRANCE

The intensive use of pesticides in modern agriculture raised concerns about their environmental fate and impacts on the ecosystems. If the monitoring of those substances in water bodies has been established in Europe since the 2000's, knowledge of soil contamination by such residues is scarce. However, the few studies addressing this issue pointed out the widespread occurrence of pesticides in soils and the risk they can pose for soil biodiversity. This study investigated 111 currently used pesticides in 47 soils sampled across France, mostly from arable lands but also from forest and grasslands theoretically exempted of pesticides applications. The sampling strategy was based on the French Soil Quality Monitoring Network to evaluate the feasibility of using an existing network for pesticides monitoring in soils. The results demonstrated the widespread contamination of almost all soils samples by residues, including untreated areas such as forests and permanent grasslands. Up to 33 different substances in one soil sample were detected, at concentrations leading to a medium to high ecotoxicological risk for earthworms in arable lands. Several frequently detected residues have never been reported in the literature so far or were found at much lower detection rates. Finally, the comparison with pesticide application records provided by the farmers revealed the unexpected presence of some substance in sites where they were not applied and a longer than expected persistence of several compounds. These findings question the fate of currently used pesticides in the environment under current agricultural practices and advocate for the monitoring of pesticides in soils at broad scales. Filling the knowledge gap of pesticide presence in soil is necessary to understand the contamination of other environmental compartments and prevent their contamination. Therefore, there is a clear need to integrate pesticide analysis in national soil monitoring programs to evaluate contamination levels, which will be conducted in France. This monitoring will include both target and non-target analyses to identify all the potential molecules in soil.

**SOIL QUALITY CLASSIFICATION BASED ON LONG-TERM DATASETS OF CLIMATE AND CROP DATA -- A CASE STUDY IN SHAANXI AND HEBEI PROVINCE, NORTH CHINA**

Y. LEI, X. LIU

The Center for Agricultural Resources Research, Institute of Genetics and Developmental Biology of CAS, Shijiazhuang, CHINA

Regional soil surveys can provide reliable information for soil quality classification. However, while the sizes of most farms in northern China are small scale with an area less than a hectare, both data of national soil survey and the annual province monitoring of soil available nutrients with 10 km scale resolutions have limited practical application. Since annual cropland biomass depends on soil quality and climate conditions, the value of biomass measurements as an indicator of soil quality is possible. This study calculates 30-year changes of cropland biomass using satellite remote sensing data in Hebei Province dominated by irrigated cropland, and in Shaanxi Province by rainfed cropland. With relevant analysis on the contribution of climatic factors to interannual fluctuations in biomass by a county scale, ten years with suitable climate conditions for crop growth is selected out of the 30 years. The average cropland biomass in these 10 years is employed to classify soil quality of cropland into five grades respectively in rainfed cropland and irrigated cropland is with a resolution of 0.5 km in two provinces. The five grades of biomass method were compared with same grades classified by both data of national soil survey data and of province network monitoring soil available NPK. The results show that biomass soil quality classification has obvious advantages in spatio-temporal resolutions, operation cost, and the correlation between grades and crop yield. Especially, in determining medium- and low-yield cropland, the grade system using biomass method have clear practical value and application prospects for agricultural policy decisions.

## 4. Soil health in achieving the Sustainable Development Goals 4.27 133609 - How will we monitor soils in the coming century?

### SOIL QUALITY CLASSIFICATION BASED ON LONG-TERM DATASETS OF CLIMATE AND CROP DATA -- A CASE STUDY IN SHAANXI AND HEBEI PROVINCE, NORTH CHINA

Y. LEI, X. LIU

The Center for Agricultural Resources Research, Institute of Genetics and Developmental Biology of CAS, Shijiazhuang, CHINA

Regional soil surveys have been proven to be reliable sources of information for classifying soil quality. However, in the northern regions of China, where small-scale farms with an area less than one hectare are prevalent, the data obtained from national soil surveys and annual province-level monitoring of soil nutrient availability at a 10 km resolution have limited practical application. As annual cropland biomass is significantly influenced by both soil quality and climate conditions, biomass measurements can be used as indicators of soil quality. Utilizing satellite remote sensing data and climate data, we calculated the changes in cropland biomass over a 30-year period in Hebei Province, which is dominated by irrigated cropland, and in Shaanxi Province, which is dominated by rainfed cropland in North China, then classified the soil quality of cropland in the two provinces into five grades based on the average cropland biomass with a resolution of 0.5 km, and compared the results with those obtained from national soil survey and province network. The results showed that the biomass soil quality classification method had obvious advantages in terms of spatial and temporal resolution, operating cost, and correlation between classification and crop yield. This classification system has clear practical value and application prospects for agricultural policy decisions in medium- and low-yield croplands.

<sup>5</sup> European Commission Joint Research Centre (JRC), Sustainable Resources Directorate, Land Resources Unit, Ispra, ITALY

<sup>6</sup> European Dynamics, Brussels, BELGIUM

Healthy soils are able to provide many ecosystem services (e.g., food provision and climate regulation), and they are generally characterized by a diverse and resilient microbial community. To constantly monitor soil health and promote its sustainable management, in 2009 the European Commission's Joint Research Centre (EC-JRC) established the European Land Use and Coverage Area Frame soil module (LUCAS Soil). Since 2018, it also measures soil biodiversity. So far the evaluation of the comparability of biodiversity data obtained from LUCAS Soil and individual EU Member States is lacking. Indeed, many factors may lead to biases, from the sampling procedure to the computational analysis.

One of the aims of the European Joint Programme on Soil (EJP SOIL) is to compare the EC with national biodiversity assessment strategies to harmonize the analytical procedures and define standard methodologies.

Over the 2022 LUCAS sampling campaign, soils from 98 locations were collected across Italy. Of these, 17 sites were sampled also following Italian strategies. DNA was extracted from soils collected in these double sampling points and bacterial 16S (V3-V4 rDNA) and fungal ITS2 regions sequenced and analysed.

Obtained data suggested that environmental variables (e.g., land cover and sampling region) have a strong significant effect on the structure of soil microbial communities, while the sampling strategy has either little or no effect. The data will be compared with the JRC's results on the same LUCAS samples (to be sequenced in 2024) to evaluate the effect of different analytical methods (e.g., DNA sequencing target and strategy). This knowledge will help defining standard procedures for setting up both a national and European monitoring networks and giving clues for data comparison and harmonization.

### IMPACT OF MEASUREMENT UNCERTAINTY ON SOC MONITORING IN AGRICULTURAL SOILS

T. TSETSKHLADZE <sup>1</sup>, G. GHAMBASHIDZE <sup>1,2</sup>, T. MESKHI <sup>2</sup>, M. TARKHNISHVILI <sup>2</sup>, G. BERUASHVILI <sup>2</sup>

<sup>1</sup> Agricultural University of Georgia, School of Agronomy and Landscape Management, Tbilisi, GEORGIA

<sup>2</sup> Scientific-Research Centre of Agriculture, Soil Fertility Research Service, Tbilisi, GEORGIA

Monitoring of changes in soil organic carbon (SOC) content is gaining more attention due to accelerated climate change. It is especially important for agricultural land assessment as farmers are requested to enhance or at least maintain existing carbon stock in soil. Despite of availability of various methods and the development of analytical techniques, it is still challenging to perform precise evaluations considering the heterogeneity of soils. Thus, it is essential to quantify the impact of sampling and analytical methods on measurement results by estimating uncertainty arising from the sampling and laboratory analysis. Uncertainty from laboratory measurement is often estimated, but uncertainty caused by the sampling is rarely taken into account.

In the current study, we measured SOC content at three experimental plots located in different soil-climatic conditions using commonly applied analytical methods such as Dumas dry combustion (DC) and Walkley-Black (WB); in addition, we used loss on ignition (LOI) as an indirect estimation of SOC, which is still used for soil fertility assessment for farmers fields. Field soil sampling was conducted using a grid method in a duplicate manner, to enable uncertainty estimation. The measurement uncertainty was estimated using classical and robust analysis of variance (ANOVA and RANOVA, respectively) from set of samples consisting from 8 to 14 pairs. The study showed that sampling has a considerable contribution to the measurement uncertainty, varying from 8.75-15.79 %, as an expanded relative uncertainty, while uncertainty caused by analytical methods varied between 2.18-2.35 % for DC, 7.05-7.84 % for WB, and 11.95-12.52 % for LOI, and total measurement uncertainty varied from 11.01 to 18.37 %. Obtained values underline the significance of the selected analytical method and sampling impact on measurement uncertainty, which can challenge the monitoring process and complicate detection of small changes in SOC content, which is normally expected is short- or medium-term periods, and thus under- or overestimate sustainability of certain agricultural practices applied in a field scale.

**Keywords:** SOC monitoring, Soil sampling, SOC measurement, Measurement uncertainty, Uncertainty from sampling

<sup>7</sup> ELISOL ENVIRONNEMENT, MONTPELLIER, FRANCE

<sup>8</sup> INRAE, PALAISEAU, FRANCE

<sup>9</sup> UNIVERSITE DE LORRAINE, NANCY, FRANCE

Despite its importance for human activities, soil biodiversity remains largely unknown and threatened. The French Soil Quality Monitoring Network (RMQS) has a significant impact in removing the grey areas through its survey of soil microorganisms and enzymatic activities. These survey have deepened our knowledge of the biogeography of microorganisms, the link with soil use and agricultural practices, and identified bioindicators of soil quality. But the RMQS could also support long-term monitoring of other components of soil biodiversity.

In 2017, the French office for biodiversity expressed the need to build a survey of soil biodiversity, which will be part of the larger survey of terrestrial biodiversity. A first experimentation based on the monitoring of 30 RMQS sites around France started in 2019, taking into account scientific and practical aspects. Biodiversity sampling was carried out all year long, by the same 12 teams as for the RMQS program, simultaneously with soil sampling and description. Bacteria, fungi and protists were monitored by DNA extraction and sequencing, as well as environmental DNA. Nematodes, mesofauna (particularly springtails), below-ground (earthworms) and surface (beetles and spiders) macrofauna were monitored by sampling and identification of specimens. This study demonstrated the feasibility of monitoring all components of soil biodiversity and lead to the writing of a manual of specifications. However, contrasting to soil microorganisms which can be monitored all along the year, results showed that soil fauna should be monitored during spring.

In spring 2024, a second experimentation based on the monitoring of 72 sites will start, involving 3 soil biodiversity experts teams to monitor the same groups as in the first test, from March to June. This experimentation will assess the feasibility of sampling more sites during a shorter period of time. The objective would be to reach the sampling of 180 sites per year, i.e. the routine level of sampling of the second RMQS campaign, to implement a comprehensive monitoring of soil biodiversity for French soils.

## 4. Soil health in achieving the Sustainable Development Goals 4.27 133609 - How will we monitor soils in the coming century?

### SOIL HEALTH DATA CUBE FOR EUROPE AT 30 M RESOLUTION

R. MINARIK, T. HENGL, L. PARENTE, X. TIAN, Y. HO, D. CONSOLI, R. SIMOES

OpenGeoHub Foundation, Wageningen, THE NETHERLANDS

Monitoring basic soil health indicators such as soil organic carbon, soil chemical properties, soil pollution, soil degradation of Europe at high spatial resolution is needed for decision making and sustainable development planning at all scales from the European Union to local landowners and land managers. The study introduces the Soil Health Data Cube builded within the AI4SoilHealth project (<https://cordis.europa.eu/project/id/101086179>). The Data Cube stacks predicted maps of basic LUCAS soil health indicators related to soil organic carbon stocks, soil nutrients and soil structure together with covariates related to static soil forming factors such as terrain and parent material (Global Lithological DB GLiM), and time-series of dynamic factors such as climate, vegetation and human intervention (e. g. CHELSA Climate, MODIS EVI and LST long-term derivatives, Bare Soil Fraction, annual tillage index, FAPAR, NDVI). Maps of soil properties are predicted spatiotemporally at 30 m resolution for 2000-2022+ for standard depth intervals (if applicable) based on the legacy point data. The main resources for training data are European surveys such as LUCAS and GEMAS, and national legacy point datasets of the member states. Predictions are based on ensemble machine learning models using Random Forest, Artificial neural network and Catboost algorithms including per-pixel model deviance, that can be used to estimate the uncertainty. The results are compared with national soil maps such as UKSO, bodemdata.nl. The Soil Health Data Cube will be published under open data license and can be used for direct analysis for research, multi scale decision making, crop-yield modeling and management planning. Moreover, the produced data can be used to simulate impact of different climate scenarios on the soil health in Europe.

### A COMPARATIVE ANALYSIS OF PLS1 AND PLS2 FOR ESTIMATING SOIL PROPERTIES USING MID-INFRARED SPECTRA

J. LEE, K.J. MIN

Seoul National University-Department of Agriculture and life science and technology, Seoul, SOUTH KOREA

Accurate and regular assessment of the biological, physical, and chemical properties of soil is crucial to understanding soil change and to properly manage soils as a natural solution to climate change. However, it takes substantial time and cost to pretreat soils and quantify soil properties. Mid-infrared spectroscopy coupled with Partial Least Squares (PLS) can be a complementary method to the conventional wet-lab assessment of soil properties. Here we leveraged 482 soil samples with known properties and assessed their mid-infrared spectra. These soils were collected under deep-rooted plants and shallow-rooted plants across 9 sites in the United States. We built PLS1 and PLS2 models on 13 soil properties and compared the model performance (R<sup>2</sup> and RMSE). PLS1 predicts a single property at a time, while PLS2 simultaneously predicts multiple soil properties. Overall, the PLS1 models outperformed the PLS2 models for the 13 properties tested in this study. However, during cross-validation, organic carbon, pH, calcium ion, magnesium ion, potassium ion, aluminum ion, and sand, silt, and clay content showed an R<sup>2</sup> difference of less than 0.05 between PLS1 and PLS2. This suggests that using PLS2 can yield comparable estimation results for soil, simplifying both the calibration and prediction procedures. As follow-ups, we will include soil biological properties such as respiration, microbial biomass, and enzyme activities in models and further compare the performance between the PLS1 and PLS2 models.

### DRY COMBUSTION BY THERMAL GRADIENT FOR SIMULTANEOUS DETERMINATION OF ORGANIC AND INORGANIC CARBON IN SOIL: A COMPARISON WITH TRADITIONAL METHODS IN SEVERAL ALPINE AND ALLUVIAL SOILS IN NORTHERN ITALY

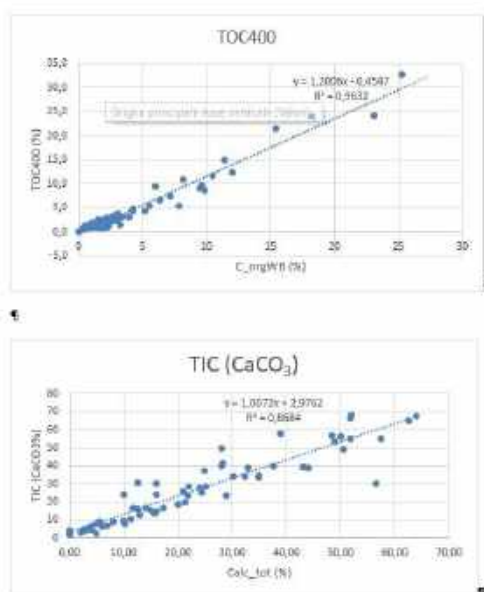

I.C. VINCI <sup>1</sup>, A. GARLATO <sup>1</sup>, S. OBBER <sup>1</sup>, F. RAGAZZI <sup>1</sup>, T. VENDRAME <sup>2</sup>, R. SCAGGIANTE <sup>2</sup>

<sup>1</sup> Soil Quality Unit - ARPAV Environmental Protection Agency of the Veneto Region, Treviso, ITALY

<sup>2</sup> Soil & Waste lab Unit - ARPAV Environmental Protection Agency of the Veneto Region, Treviso, ITALY

SOM is recognized as the most important indicator of soil quality and fertility. In view of the monitoring that will hopefully be implemented by the upcoming SML, reliable and environment-friendly methods are needed for the quantification of SOC. Meanwhile, comparison of methods is of utmost importance to exploit soil data collected in the past, to assess carbon stock variations in the long term with a high level of confidence. The "Temperature dependent differentiation of total carbon (TOC400, ROC, TIC900)" method has been recently published (October 2023) as European standard EN17505 and represents an evolution of the classic dry combustion method (ISO 10694:1995), allowing to analyze larger samples, overcoming the critical issue of sample homogenization, and to differentiate and determine organic and inorganic carbon in one single analytical run. Among the 589 Soil Typological Units described by the "Soil Quality Unit" of ARPAV in the 18.000 km<sup>2</sup> of the Veneto region, within soil maps at 1:250.000 and 1:50.000 scale, 100 topsoil samples were chosen, as representatives of different soil types. Climates, landscapes and parent materials range from coastal dunes and lagoon reclamation areas to alluvial plains of different ages, from pre-glacial maximum to late Holocene, together with hilly and mountain reliefs on different lithologies, from calcareous to siliceous. 12 WRB soil groups were represented, 7 USDA soil orders and 43 subgroups. Samples from the regional soil sample archive (17,000 soil samples collected during 30 years) formerly analyzed by Walkley Black for TOC and ISO 10693 for CaCO<sub>3</sub> were re-analyzed by the new EN17505 method in the "Soil and Waste Unit" of ARPAV lab.

Samples ranged from 1 to 328 g kg<sup>-1</sup> organic carbon content, from absent to 685 g kg<sup>-1</sup> CaCO<sub>3</sub>. Results showed high consistency between the different methods with recovery comparable to those reported in literature for dry combustion vs wet chemistry methods, for organic carbon (TOC400, fraction decomposing at temperature <400°C), and vs volumetric method, for inorganic carbon (TIC900).

## 4. Soil health in achieving the Sustainable Development Goals 4.28 133610 - Characterizing and selecting soil health indicators at various scales

### IS SOIL QUALITY COMPATIBLE WITH SOIL ORGANIC CARBON CAPACITY OF THE ALLOPHANIC SOIL IN NORTHERN JAPAN?

M. YOSHIMURA <sup>1</sup>, K. KURAMOCHI <sup>2</sup>, Y. TOMA <sup>2</sup>

<sup>1</sup> Hokkaido Agricultural Research Center, National Agriculture and Food Research Organization, Sapporo, JAPAN

<sup>2</sup> Soil Science Laboratory, Research Faculty of Agriculture, Hokkaido University, Sapporo, JAPAN

Efforts to quantify soil quality involve computing a Soil Quality Index (SQI) by assessing soil physicochemical properties. Enhanced soil management, optimizing the material cycle, aims to ameliorate soil health with organic matter (OM) input for improved properties. Augmenting carbon sequestration in soil is pivotal for enhancing soil quality and health, given the substantial carbon reservoir. The maximal quantity of mineral-associated organic carbon (MOCmax) is approximated by the clay and silt content (CS). Carbon saturation (C<sub>sat</sub> = MOC / MOCmax) is derived from MOCmax. However, C<sub>sat</sub> data in allophanic Andosols are scant, raising uncertainty about the contribution of applied OM to soil physicochemical properties. This study in northern Japan estimated MOCmax and C<sub>sat</sub>, exploring the correlation between these parameters and soil properties.

The Minimum Data Set (MDS), selected by principal component analysis, is used to calculate the SQI. Indicators in MDS are weighted according to variation magnitude, and the SQI is computed by aggregating these weighted scores. The proportion of MOC in total carbon and MOCmax are determined by referencing from precedent studies' value and formula which is directly proportional to CS.

The study's average C<sub>sat</sub> is approximately 10%, below the global arable land average. Weighted scores for the solid phase correlate positively with MOCmax and C<sub>sat</sub>, while scores for easily available moisture exhibit a significant negative correlation solely with MOCmax. Soils with high CS and high MOCmax may cause pores to be easily filled with fine particles by compaction, decreasing solid phase scores, and high MOCmax may decrease C<sub>sat</sub>. Findings suggest that OM input would not only increase soil carbon storage but also improve SQI in this region, posing an improbable carbon saturation there. Acknowledging inaccuracies in MOC and MOCmax estimations and potential MOCmax underestimation due to allophanic characteristics is imperative. Systematic collection and organization of these data would facilitate proposing a comprehensive soil health index, integrating SQI and C<sub>sat</sub>.

In intensive vegetable production systems, cover crops (CC) are usually incorporated into the soil by disking prior to the subsequent crop. In recent years, silage tarps have gained popularity amongst farmers in Quebec as a suitable tool for no-till cropping systems. Termination of CC by roller-crimping is another strategy used by organic farmers. However, these practices have not been studied extensively in vegetable cropping systems in Eastern Canada. Our main objective was to assess the impact of CC termination with or without tillage on soil health indicators. A 2-year field experiment (2022-2023) was conducted on a clay loam at a research site in Saint-Augustin-de-Desmaures, QC, Canada. In both years, a spring-seeded CC mixture was terminated mid-summer, followed by a vegetable crop. In 2022, a mixture of field peas and oats was seeded, while in 2023, the CC mixture consisted of field peas and faba beans. Treatments were arranged in a split-plot design with four blocks. Four CC termination systems (whole plot factor) were evaluated before vegetable transplanting: 1) roller-crimping, 2) flail-mowing and tarping, 3) flail-mowing and incorporation by disking, and 4) a fallow control with no-CC. The subplot factor was the fertilization rate of vegetable crops based on nitrogen recommendations (0%, 50%, and 100%). After the termination of CC, broccoli and beetroot were transplanted in 2022 and 2023, respectively. At harvest time, soil samples were collected at a 0-10 cm depth, and soil health indicators were measured using soil-based lab tests. Using CC resulted in a higher proportion of water-stable aggregates (>2mm) and a larger mean-weight diameter of stable aggregates compared to the no-CC control. Soil respiration values were higher in the treatments with CC than in the no-CC control, and soil bulk density was higher in the roller-crimped CC treatment than in the other treatments. Our results showed that establishing spring-seeded CC into organic vegetable production systems, regardless of termination methods, offers some soil health benefits in the short-term.

Most ecotoxicological investigations assessing Cu-toxicity use metal-spiked soils, while research on real-world Cu-contaminated soils remains limited. At present, there are no studies using earthworm-based bioassays to evaluate Cu toxicity of agricultural soils contaminated with Cu-based pesticides. The main restriction for utilizing real-world contaminated soils for ecotoxicity assessment pertains to multi-metal pollution. Agricultural soils subjected to Cu-based pesticide application provide a distinctive example of soils contaminated predominantly with one metal. This study aimed to establish levels of Cu-toxicity in Cu-based pesticide polluted agricultural topsoils for earthworms. Forty topsoils (0-5 cm) from orchards and vineyards of central Chile, along with 10 soils under native wild vegetation (background soils), were sampled. Given the vital ecological role played by earthworms, a standardized avoidance bioassay utilizing *Eisenia fetida* was employed to gauge the impact of copper-based pesticides on the soils under study. Results showed that total copper in soils ranged between 23 and 566 mg kg<sup>-1</sup>, with toxic effects on earthworms in select soils. As determined through the avoidance response of *Eisenia fetida*, the effective concentration at 50% (EC50) of total soil copper was found to be 240 mg kg<sup>-1</sup>, with a 95% confidence interval of 193-341 mg kg<sup>-1</sup>. Findings of the present study are significant as the EC50 value obtained is consistent with the EC50 values derived from other investigations that utilized actual contaminated soils. Assessing the soil health in agricultural areas is a fundamental task, particularly in the context of climate crisis, where soil degradation is perceived as one of the primary threats facing contemporary society. Proper management of these spaces is a priority action for maintaining food security and achieving sustainable development goals. In this regard, it is imperative to develop sustainable and effective adaptation strategies, understanding the need to promote the application of robust methodologies for monitoring various soil health indicators (physical, chemical, and biological). Thus, it is essential to promote practices and treatments aimed at enhancing soil resilience to new changing conditions. Under this paradigm, this study aims to evaluate the soil health status based on different physicochemical indicators in a representative experimental plot of nectarine cultivation in the province of Zaragoza (Spain). The study investigates the impact of a treatment based on the use of multifunctional cover crops based on LivinGro® (CCM) on these indicators. Soil samples were collected every two months over three years, evaluating different indicative properties in (i) a control zone (without CCM treatment) and (ii) a zone with CCM treatment (LivinGro®). The results show the effects of this treatment on the soil. The main analyzed properties indicate that the LivinGro®-treated zone is improving soil health, particularly in key indicators such as basal respiration, organic carbon, nitrogen, and porosity. Likewise, climatic variability, specifically existing seasonal rainfall differences, has been identified as a determining variable in the results analysis.

<sup>4</sup> Competence Centre for Plant Health, Free University of Bozen-Bolzano, Bolzano, ITALY

The significant inputs of agrochemicals and intensive grape production dramatically affect soil health and fertility. This work aims to identify the biotic and abiotic drivers and the keystone species influencing soil health, applying an innovative agroecological network analysis in vineyards in the function of their management and geographic location. The sampling area is in South Tyrol (Italy), one of Italy's highest-quality areas for viticulture, covering around 5380 ha (2% of the total agricultural land). Samples associated with *Vitis vinifera* cv. Pinot noir were collected from 42 vineyards (22 biological and 20 conventional) distributed over a geographic gradient from south to north over two seasons (spring and autumn). Samples were analyzed for the following chemical parameters: Total organic carbon (TOC), total organic nitrogen (TON), dissolved organic carbon (DOC), available phosphorus (P-Olsen), pHCaCl<sub>2</sub>, and the extractable fraction of elements. Results showed that conventional vineyards had significantly higher TOC, TON, DOC, zinc, and sulfur concentrations compared to biological vineyards ( $p < 0.03$ ), while the pHCaCl<sub>2</sub> was significantly higher in biological vineyards compared to conventional (6.41 vs 5.98, respectively;  $p < 0.05$ ). Regarding geographic pattern, in conventional vineyards, the TOC, TON, DOC and pHCaCl<sub>2</sub> were significantly lower in northern areas compared to central and southern areas ( $p < 0.05$ ). In biological vineyards, the DOC was significantly higher in the northern area ( $p < 0.05$ ) compared to the central and southern areas ( $p < 0.05$ ). TOC and pHCaCl<sub>2</sub> were significantly higher in central and southern areas compared to the northern ( $p < 0.05$ ). The TON in biological vineyards was not affected by geographic patterns. The available P was similar between the agricultural management and among the geographic areas. Further analysis will be conducted to characterize the agrochemical residues and soil biodiversity (i.e., bacteria, fungal, and fauna diversity) based on the DNA metabarcoding approach. Abiotic and biotic data will be integrated to unravel possible keystone species quality indicators using the (agro)ecological network analysis approach.

### HOW TO LINK SOIL QUALITY, SOIL HEALTH, SOIL-BASED ECOSYSTEM SERVICES, AND SOIL THREATS? THE SERENA CONCEPTUAL FRAMEWORK

I. COUSIN <sup>1</sup>, D. MONTAGNE <sup>2</sup>, R. ANTON-SOBEJANO <sup>1</sup>, O. SCAMMACCA <sup>2</sup>, J. DE HAAN <sup>3</sup>, E. VAN DEN ELSEN <sup>3</sup>

<sup>3</sup> WUR, Wageningen, THE NETHERLANDS

To reach the EU ambitious objective of 70% of healthy soils by 2030, we need to evaluate sustainable management practices dedicated to the restoration of degraded soils. It is then of prime importance to define what means “healthy soils”, especially regarding the older concept of “soil quality”, and the usual concept of “soil threats”; the links between these soil-related concepts remain partly unclear and may limit our ability to evaluate some management practices. In the context of the EJP SOIL programme, the SERENA consortium has proposed a framework to interconnect the key concepts like Soil Quality, Soil Health and Soil Ecosystem Services, and Soil Threats. Some definitions of these concepts have first been browsed from the literature, from which new or modified definitions have been ranked by the SERENA participants. The conceptual framework of the SIREN project has then been modified: it is mainly based on 2 interlinked boxes, representing the agricultural and socio-economic systems. Ecosystem Services (ES) are here considered i) either as a supply from the ecosystem, or ii) as a use by the socio-economic system; the latter is the part of the ES supply directly or indirectly used or experienced by the society. The latter is responsible for the pressures on the whole system: it can either increase threats on soils (through the increase of cultivated land areas or intensification of agricultural practices, for example), or improve Soil Quality, Soil Natural Capital, and ES supply (thanks to agricultural practices increasing soil carbon stocks, for example). In this framework, Soil Quality and Soil Threats are conceptualised at the interface between the ecosystem and the socio-economic system, and a Soil Health threshold – considered as a critical level of Soil Quality – helps defining whether soils are healthy or unhealthy. We hope such a framework would enhance scientific research about soil-based ecosystem services, and favor a good communication with the policy-makers and the public.

### DUAL NATURE OF SOIL STRUCTURE: THE UNITY OF AGGREGATES AND PORES

A. YUDINA <sup>1</sup>, Y. KUZYAKOV <sup>2</sup>

<sup>1</sup> V.V. Dokuchaev Soil Science Institute, Lab. of Soil Physics and Hydrology, Moscow, RUSSIA

<sup>2</sup> University of Gottingen, Department of Soil Science of Temperate Ecosystems, Department of Agricultural Soil Science, Gottingen, GERMANY

Soil is a hierarchical, self-organizing, and emergent system that supports plant and microbial growth, enables carbon sequestration, facilitates water fluxes, and provide habitat for microorganisms, all of which depend on soil structure. Recent debates have generally reduced soil functioning to geometry and topology of soil solids and pores and denied the existence and role of soil aggregates and hierarchy of solids. Here we argue that soil structure has a dual nature that essentially boils down to the interlocking of pores and solids in groupings of specific complexity and dynamics called aggregates. By comparing their architectural, chemical, and energetic parameters, we conclude that aggregates have a much higher information density than pores. Therefore, aggregates (as unity of solids and pores) perform much broader range of functions compared to pores alone, especially in long-term. A set of soil functions corresponding to each level of the soil structure hierarchy depends on aggregate type (macroaggregates, water-stable aggregates, microaggregates, and elementary soil particles) determined by their specific binding energy, dynamics, and lifetime. The introduced here energy-based concept justifies the hierarchy of soil structure, and is the base for the selecting indicators of soil functions. We understand the soil structure implying the energy-based approach: each hierarchy level corresponds to specific bonding strength of mineral and organic particles forming aggregates. The duality of soil structure is manifested not only in the relationship between pores and solids in aggregates, but also in the interactions and competition between the biological and non-biological processes that aggregate and disaggregate the structure. The view of the pore space as a transport pathway and habitat for soil living phase and plant roots, the solid-pore interface as a setting for physico-chemical and biological transformations, and aggregates as a result of these phenomena, provides a context for mechanistic understanding and process-based modeling of soil functions and health.

<sup>3</sup> Doctoral School, Universidad de Alcalá (UAH), Alcalá de Henares, 28805 Madrid, MADRID, SPAIN

Terrestrial ecosystems play a crucial role in providing essential services for life, but land use and management can trigger problems such as soil degradation, habitat loss and pollution. Soil microorganisms are fundamental in the biogeochemical cycles that support life and thus the fertility of agricultural systems. This research focuses on the use of molecular markers to evaluate changes in bacterial and fungal guilds linked to C and P cycling promoted by established agricultural practices in a rainfed olive grove. A trial was conducted in an intensive olive orchard with 238 trees-ha<sup>-1</sup> (7 x 6 m spacing) at the La Chimenea Experimental Farm (IMIDRA) located in southern Madrid. Four types of soil management were tested: i) conventional tillage, ii) permanent grass cover (*Brachypodium distachyon* (L.) P. Beauv.), iii) permanent spontaneous vegetation and iv) annual legume crop (*Bitter vetch* (L.) Willd). Soil sampling was carried out at four depths (0-5 cm, 5-10 cm, 10-20 cm and 20-30 cm) for the analysis of specific physical, chemical and microbiological properties. Microbiological analysis consisted of extracting DNA from soil samples and quantifying it by qPCR. The target markers we used were BFG3 and FGH3 markers for bacteria and fungi linked to beta-glucosidase activity and *phoD* for bacteria linked to phosphatase activity. The results indicate that the abundance of *phoD* and BFG3 were not significantly influenced ( $p > 0.05$ ) by treatments, however, the abundance of FGH3 showed a clear differentiation between cover crops. The results seem to indicate that yeros and spontaneous vegetation mainly promote the abundance of fungi linked to beta-glucosidase activity in the soil.

**Keywords:** agricultural systems, legume crop, qPCR, Soil health indicators, Biogeochemical cycle

### SOIL PROPERTIES AND THEIR RELATIONSHIP WITH WINE PRODUCTION IN MAIPO VALLEY, CHILE.

D. GODOY SEPULVEDA<sup>1</sup>, O. SEGUÉL<sup>2</sup>, S. VARGAS<sup>3</sup>

<sup>1</sup> University of Chile, Faculty of Agronomic Sciences, Graduate School., Santiago, CHILE

<sup>2</sup> University of Chile, Faculty of Agronomic Sciences, Graduate School., Santiago, CHILE

<sup>3</sup> Viña Concha y Toro, Center for Research and Innovation., Santiago, CHILE

Central Chile's wine production is recognized worldwide for its quality; however, soil variability generates changes in the oenological potential of the grape berry. In this study, Entic & Fluventic Haploxerolls soils were characterized in a 100 hectares cultivated with 20-year-old Cabernet Sauvignon vines. Soil pits and soil sampling were performed and physical properties (bulk density, water retention, macroporosity, texture) up to rooting depth and chemical properties (pH, EC, OM, macro and micronutrients, CEC) were evaluated for the first two soil horizons. The spatial variability of soil properties presents normal ranges, with extreme values from 1.12 to 14.84 mg/kg of N, 5.08 to 80.9 mg/kg of P, 0.74% to 3.99% of OM and from 14.79 to 35.50 cmol (+) /kg of CEC. CEC showed a dependence on both clay and OM content, highlighting vineyard managements that consider the application of compost to the soil. As expected, the water constants (FC and PWP, water retention at -33 and -1500 kPa) showed a direct linear relationship with the level of clay in the soil, although the presence of coarse fragments determines the available water storage capacity, which varies between 38 and 140 mm. Aeration porosity showed an inverse linear relationship with clay, reaching restrictive levels with values of Clay higher than 27%. Soil characterization and clustering will allow to apply differentiated strategies for management optimization in aim to produce a high-quality wine.

<sup>5</sup> Washington State University, Prosser, USA

<sup>6</sup> United State Department of Agriculture - ARS, Prosser, USA

The state of Washington, USA, established the Washington Soil Health Initiative (WaSHI), which is a partnership among the Washington State Conservation Commission, the Washington State Department of Agriculture, and Washington State University. The Washington Soil Health Initiative promotes collaborative research, education, and technical assistance activities that identify, promote, and implement sound soil health stewardship practices. These practices should be economically viable and voluntary for farmers and ranchers across the diverse agricultural communities, climates, and geographies in Washington. The initiative aims to achieve this through demonstration projects and engaging in rigorous long term soil health research. Six long-term agroecological research and extension (LTARE) sites representing Washington's diverse agricultural systems were established, one being a long-term soil health research vineyard at Washington State University's Irrigated Agriculture Research and Extension Center in Prosser. The LTARE soil health research vineyard is believed to be the first publicly funded long-term research vineyard specifically designed to evaluate how management practices impact soil health, vine health, and grape and wine quality in the United States. Research conducted at the soil health vineyard is guided by industry stakeholders and seeks to recontextualize soil health metrics for vineyards in arid regions by investigating the influence of soil health building practices on young vine vigor and vineyard establishment success. Over time, we will transition our research goals to evaluate the influence of soil health building practices on vine vigor, grape yield and quality, and wine quality. This presentation will cover the development and projection of Washington's Soil Health LTARE projects, using the research vineyard site as an example.

### EVALUATION OF SOIL INDICATORS AND SOIL FUNCTIONS UNDER DIFFERENT AGRICULTURAL MANAGEMENT PRACTICES

F. HÄFNER<sup>1</sup>, F. WALDER<sup>1</sup>, G. GARLAND<sup>2</sup>

<sup>1</sup> Agroscope, Reckenholz, SWITZERLAND

<sup>2</sup> ETH Zürich, Zürich, SWITZERLAND

Agricultural management has a strong impact on soil quality, while pedo-climatic conditions set the site-specific boundaries for soil functions. Optimizing the multiple soil functions within site limitations is key for sustaining soil health and increase the soil's resilience towards climate change. In this context, the Bodencockpit project aims to provide an easy-to-use methodology and set of practical and sensitive indicators to evaluate soil quality and management at the plot level for arable and mixed farms in Switzerland. The selected soil state indicators include: physical (bulk density (BD), air capacity (AC), visual evaluation of soil structure (VESS), penetration resistance), chemical (SOC/clay, permanganate oxidizable C, total N and P, available P, K, and Mg, pH, cation exchange capacity, base saturation) and biological (earthworms, soil respiration, microbial biomass C, enzyme activity) soil properties. Scoring curves, based on a thorough literature review, were generated to normalize and rate the indicators against critical and optimal threshold values. Normalized scores, ranging from 0 to 1, show the fulfillment of the site-specific potential of an indicator. Indicators were aggregated, where applicable, to assess water storage capacity, soil structure maintenance, C storage, nutrient cycling, and biological activity. Four long-term field experiments (LTEs) in Switzerland were sampled in spring 2023, including 14 treatments, to evaluate the impact of specific managements at optimal fertilization. The first results from eight of the tested LTE treatments indicate differences in physical soil indicators among treatments. The water storage capacity, calculated from field and air capacity, was rated 0.9-0.95, suggesting conditions close to its potential. Normalized scores for effective BD ( $BD + 0.009 \times \text{clay}\%$ ) were 0.58-1.0, 0.39-0.64 for AC, and 0.19-0.72 for SOC/clay. The aggregated harmonic mean of the normalized scores for the soil structure maintenance function ranged from 0.40-0.71, with highest scores for the bio-dynamic treatment. Differences among indicators and functions will further be related to soil management indices, providing a decision support tool in soil quality optimization.

### A STATISTICAL APPROACH TO QUALITY ASSESSMENT OF POST-FLOOD SOILS OF SOUTHERN KERALA

A. MATHEW, R. B.

Department of Soil Science and Agricultural Chemistry, College of Agriculture, Kerala Agricultural University, Trivandrum, INDIA

After the devastating floods of 2018, a detailed study was executed to assess and depict the quality of post flood soils of the Central and Southern foothills agroecological unit in Kerala. In order to work out soil quality indices, seventy five georeferenced surface samples were collected from the severely flood affected areas within the agroecological unit and characterized in the laboratory for physicochemical and biological properties. Seventeen selected soil properties, namely, bulk density, water holding capacity, water stable aggregates, per cent of sand, silt and clay, pH, EC, organic carbon, available N, P, K, Ca, Mg, S, B and acid phosphatase activity from the laboratory characterization were analyzed using Principal Component Analysis (PCA). Thus, a Minimum Data Set (MDS) of nine parameters retained in six principal components with eigen value greater than one was obtained. The selected indicators were categorized into 4 classes, viz., very poor, poor, good and very good and assigned with scores 1, 2, 3 and 4 respectively. A weighted Soil Quality Index (SQI) was developed by combining the scores after assigning appropriate weights to the parameters. Weights were assigned based on existing soil conditions, cropping pattern and agro-climatic conditions. The soils were rated as poor (<50%), medium (50-70%) or good (>70%) based on the soil quality index per cent. Soil quality was found to better in pockets with silt deposition which has resulted in moderately acid to neutral pH and relatively higher available K, Ca, Mg and B while majority of the post-flood area studied exhibited medium soil quality. <FILE IMAGE='1931\_20240311170111.jpg'> Spatial variability in soil quality was mapped in ArcGIS software using the spatial analyst tool - Inverse Distance Weighted (IDW) method of interpolation.

### INDICATORS-BASED ASSESSMENT OF SOIL-BASED ECOSYSTEM SERVICES AT DIFFERENT SPATIAL SCALES IN EMILIA-ROMAGNA (NE ITALY)

R LORENZETTI <sup>1</sup>, C CALZOLARI <sup>1</sup>, P TAROCCO <sup>2</sup>, A APREA <sup>2</sup>, E MEDINA-ROLDÁN <sup>1</sup>, F UNGARO <sup>1</sup>

<sup>1</sup> Consiglio Nazionale delle Ricerche, Istituto per la BioEconomia (CNR IBE), Sesto F.no, ITALY

<sup>2</sup> Regione Emilia-Romagna, Area Geologia Suoli e Sismica, Bologna, ITALY

Spatial assessments of soil-based ecosystem services (SES) are useful frameworks providing information on ecosystem multifunctionality and to estimate effects of climate change and land use change on SESs supply. This contribution presents an indicators-based approach to SES assessment and mapping at different spatial scales in Emilia Romagna (NE Italy). At regional scale, the information from soil database has been used to assess and map standardised and re-scalable indicators of potential soil ecosystem service supply resorting to digital soil mapping and geostatistical simulations at a 100m resolution over the entire region (22510 sq. km). To tackle the multifunctionality of soil, the following SES have been considered as indicated by local stakeholders: habitat for soil biodiversity, buffering capacity, carbon sequestration, food provision, biomass provision, erosion control, water regulation and water storage. In addition, an overall soil quality index based on selected SES is assessed and mapped. A relevant feature of the approach is that is it scalable at different implementation scale. The information about SES provision is made available by the regional soil service to provide the legally binding information that each municipality must take into consideration to produce or update the General Urban Plan, which is the most important instrument of land and urban planning. Upon request of the Municipality of Forli, an ad hoc soil survey has been made to assess and map SESs at the local scale (25 m resolution in urban area) to deliver information and maps at a finer resolution taking explicitly into account the properties and services of urban and peri-urban soils along with the benefits delivered to citizens. Our results for the local extension show by one side, the need of specifically dedicated surveys for properly quantifying SESs in an urban environment due to the inherent soil complexity, and by the other one, that, despite embedded within the urban landscape, urban soils provide important SESs to be accounted for in land development and urban design plans.

### TIME FRAMES AND PEDOLOGICAL IMPLICATIONS OF AEOLIAN ACTIVITY IN THE FLUVIOGLACIAL LANDSCAPE OF THE WHITE FOREST (CENTRAL POLAND)

J. JONCZAK <sup>1</sup>, B. KRUCZKOWSKA <sup>1</sup>, K. SZTABKOWSKI <sup>2</sup>, T. ZWIAZEK <sup>3</sup>

<sup>1</sup> Warsaw University of Life Sciences - SGGW, Warsaw, POLAND

<sup>2</sup> Forest Research Institute, Sekocin Stary, POLAND

<sup>3</sup> Institute of Geography and Spatial Organisation, Polish Academy of Sciences, Warsaw, POLAND

The White Forest represents a fluvio-glacial landscape that developed during the retreat of the ice sheet of the Middle Polish Glaciation and was transformed under periglacial conditions in the foreland of the Last Glacial Maximum. Fluvio-glacial deposits form a layer of varied thickness, and their surface was affected by aeolian processes. The main phase of aeolian activity is attributed to periglacial environment, but little is known about aeolian processes during the Holocene. In this study, we aimed to identify time frames of Holocene aeolian activity and its impact on soil cover, including soil-forming processes, morphology, classification and chosen characteristics. Based on maps, LIDAR-based digital elevation model, literature data and field reconnaissance, we selected 30 locations representing different topographic positions, sediment stratigraphy, and varied intensity of aeolian processes in the past. A soil pit was done in each location. Soils were classified and described according to WRB (2022) standards and sampled. A wide spectrum of physical and chemical properties were determined using standard procedures in soil science. Additionally, radiocarbon dates were obtained for buried horizons. Our study indicates a spatially variable intensity of aeolian processes during the Holocene. The highest intensity was recorded along the valleys of the Narew and Bug rivers, while it was generally low in the interior of fluvio-glacial plain. Radiocarbon dates indicate the last 1500 years as time frames of accelerated aeolian activity. Aeolian processes have significantly altered the soil cover, which is dominated by Arenosols. Complete or partial erosion of soils, deposition of eroded material on existing soils and their burial, changes in mineralogy and textural characteristics of mineral substrates and their stratigraphy (development of lithological discontinuities) were the main fingerprints of aeolian activity in the study area. As a result of these changes, the heterogeneity of the soil cover increased considerably in terms of soil-forming processes, morphology, classification, physical characteristics and pools of various substances (soil organic matter, nutrients, sesquioxides).

### CND NUTRITIONAL STANDARDS AND THEIR RELATIONSHIP WITH THE SOIL IN VINE PRODUCTION AREAS

D.E. ROZANE<sup>1</sup>, F.C. MEDEIROS<sup>1</sup>, M.P. CONCEIÇÃO<sup>2</sup>, G. BRUNETTO<sup>3</sup>

<sup>1</sup> Universidade Estadual Paulista - Departamento de Agronomia e Recursos Naturais, Registro, BRASIL

<sup>2</sup> Universidade Federal do Paraná - Departamento de Ciências do Solo, Curitiba, BRASIL

<sup>3</sup> Universidade Federal de Santa Maria - Departamento de Solos, Santa Maria, BRASIL

The chemical analysis of plant tissue, combined with the chemical analysis of the soil, are basic tools for evaluating the nutritional status of plants and help make recommendations for correctives and fertilizers. Thus, developed concepts of interpretation and diagnosis of nutritional status, especially those of a multivariate approach, associated with soil analyzes are necessary to advance fertilizer recommendation techniques, being complementary and alternative to long-term calibration experiments. Therefore, it is important to use current parameters, built in commercial environments that take advantage of current production bases associated with monitoring productivity and soil diagnostics and nutritional status. The study aimed to establish norms and fertility classes for the 'APPC 007 estela' vine (*Vitis vinifera*). To achieve the proposed objectives, productivity data and chemical analyzes of soil and leaf tissue from 95 commercial plots of 'APPC 007 estela' vine, sampled in the 2022/2023 harvest, in the region of Pilar do Sul, state of São Paulo, were used Brazil. The Nutritional Composition Diagnosis – CND methodology was used to establish standards for the nutrients N, P, K, Ca, Mg, S, B, Cu, Fe, Mn and Zn. The chemical attributes of the soil analyzed were: pH, M.O., P, K, Ca, Mg, H+Al, S-SO<sub>4</sub>, B, Cu, Fe, Mn and Zn, and those calculated as Base Sum (S.B.); Cation Exchange Capacity (C.T.C.) and Base Saturation (V%). Considering the correlation matrix, the significant correlation coefficients (r) between the CND indices in the plant presented the highest relationships between them (66%), followed by the soil (50%), with soil attributes and nutritional indices having approximately 23%. The correlations between profitability per area (\$/ha) occurred positively for the nutritional indices of P and Cu, and negatively for S, Mn, Zn and CND-r<sup>2</sup>, for soil attributes the only positive correlation was for Fe and negative for K and B. Profitability per area was more related to the nutritional indices of the plant than to those of the soil.

### THE IMPORTANCE OF AN INTEGRATED APPROACH BASED ON NATURE-BASED SOLUTIONS (NBS) TO ADDRESS THE COMPLEXITY OF LAND DEGRADATION AND RISK OF DESERTIFICATION

V. RASTELLI, S. D'AMBROGI, F. ASSENNATO

Institute for environmental protection and research, Rome, ITALY

Emphasizing integrated approaches based on Nature-Based Solutions (NbS) is crucial to address the complexity of land degradation phenomena and the diverse threats affecting drylands and areas at risk of desertification. This literature review moves from the experience of the Newlife4Drylands Life preparatory project to explore the potential opportunities for the application of NbS for soil management and restoration and for their medium and long term monitoring.

By employing a search strategy that included criteria such as Nature-Based Solutions, soil threats, restoration, and land degradation, the review systematically identified relevant literature from electronic databases like Scopus and Web of Science.

The results highlights the importance and complexity of scaling up successful practices against land degradation taking into account the adaptability to different contexts. It also underscore the imperative for climate-resilient NbS, tailored to bolster soil resilience amidst changing climatic conditions.

Technological advancements, such as applications from remote sensing, reveal as crucial to effective and economic feasible NbS monitoring, allowing real-time assessments for adaptive management and supporting scaling out of solutions to other contexts. In addition economic valuation of NbS, complemented by incentive programs, proves vital for garnering stakeholder and policymaker support.

The study underscores the pivotal role of NbS in sustainable soil management and restoration, offering valuable insights for future research initiatives and policy frameworks.

### THE TRANSPORT OF LABELLED NEAR-NATURAL COLLOIDS IN SOIL

A. DE MATTEIS, N. SIEBERS, L. WEIHERMUELLER, A. .E. BERNS

Forschungszentrum Jülich - Agrosphere, Jülich, GERMANY

Ensuring the vitality of forest ecosystems necessitates a profound understanding of nutrient cycling, with a critical yet understudied aspect being the role of colloidal transport in phosphorus (P) cycling. This study delves into the largely unexplored mechanisms of colloidal transport, necessary for holistic ecosystem perspectives and numerical modeling of nutrient cycling. The complexity lies in the unknown soil source strength, motivating the need for column transport experiments under varied soil properties and hydraulic conditions.

Iron (Fe) is one of the most abundant elements found in soil colloidal fractions and possesses the advantage of featuring several stable, non-radioactive isotopes. To mimic natural colloids leaching, we isolated labeled near-natural colloids from a  $^{57}\text{Fe}$ -labeled agricultural soil previously used in a nutrient uptake experiment with barley. Both free and occluded soil colloids were then extracted from this labeled soil and its unlabeled control through wet sieving. Subsequent digestion and elemental analysis via ICP-MS provided insights into the feasibility and detectability of  $^{57}\text{Fe}$ -labeling. Notably, ICP-MS analysis unveiled an association of P, K, and Ca, which were more prevalent in the free colloid fraction, while Mg and Fe exhibited greater abundance in the occluded colloid fraction. This phenomenon could be attributed to the heightened surface area and reactivity of fine particles.

Isolated free and occluded colloids from the labeled soil were then employed in saturated column experiments. Breakthrough curves were obtained through leachate samples analyzed with Triple-Quad-ICP-MS. This research contributes to understanding colloidal transport dynamics under saturated conditions and offers insights into a novel method to use isotope label to trace colloids.

### PH DEPENDENCE OF AS(III) OXIDATION BY POLYETHYLENEIMINE MODIFIED MAGNETIC MESOPOROUS POLYDOPAMINE NANOCOMPOSITE: ROLES OF REDOX-ACTIVE FUNCTIONAL GROUPS

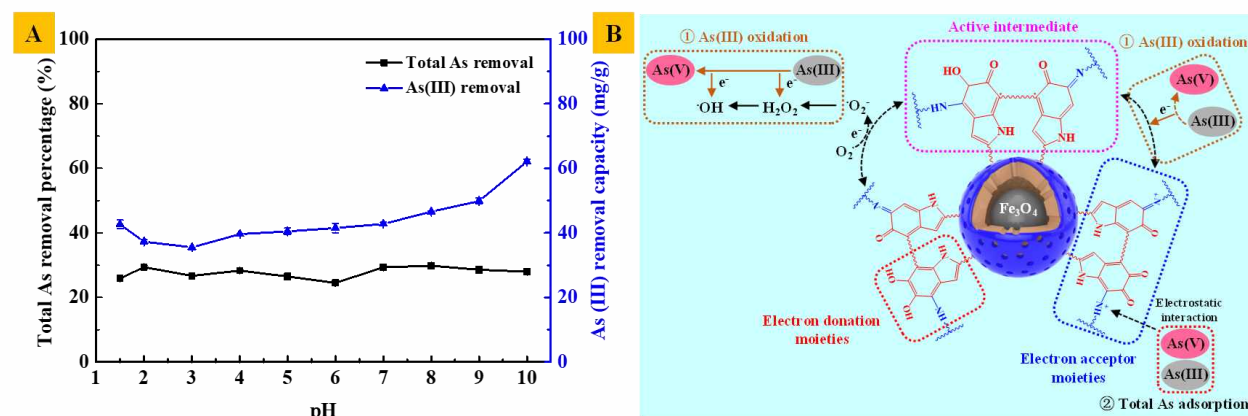

Q. YANG <sup>1</sup>, Z. DANG <sup>2</sup>, L. ZHANG <sup>1</sup>

<sup>1</sup> School of Chemistry and Chemical Engineering, South China University of Technology, Guangzhou City, CHINA

<sup>2</sup> School of Environment and Energy, South China University of Technology, Guangzhou City, CHINA

Arsenic(III) (As(III)) is recognized as one of the most hazardous heavy metal pollutants because of its characteristics including accumulation and nondegradability in soil[1]. Polydopamine (PDA), an environmentally friendly biopolymer, contains a large number of electron-rich groups (such as amino, imine, catechol, and quinone, etc.) which is a promising candidate material for As(III) pollution remediation[2]. To overcome these drawbacks of the environmental instability in PDA-based adsorbents, a novel PEI-modified magnetic mesoporous polydopamine nanocomposite (Fe<sub>3</sub>O<sub>4</sub>@mesoPDA/PEI) was prepared for As(III) adsorption. Fe<sub>3</sub>O<sub>4</sub>@mesoPDA/PEI was a uniform porous spherical structure with an average pore size of 19.70 nm. Meanwhile, the adsorption interface had abundant redox-active functional groups (i.e. catechol, quinone, and amino/imino), in favor of the highly toxic As(III) oxidation. Moreover, its magnetic saturation value was 23.7 emu/g, which could meet the demand for magnetic enrichment and separation after adsorption within a few seconds.

The adsorption behavior of As(III) was highly pH-dependent. The As(III) adsorption performance of Fe<sub>3</sub>O<sub>4</sub>@mesoPDA/PEI increased with the increase of the initial pH values while the removal capacity of total As was almost independent of the initial pH values. Notably, the adsorption capacities of total As were far lower than those of As(III) in the range of pH = 1.5-10.0, implying that the adsorption of As(III) on Fe<sub>3</sub>O<sub>4</sub>@mesoPDA/PEI involved two processes including the oxidation of As(III) to As(V) and the adsorption of As(V). The quinone group of Fe<sub>3</sub>O<sub>4</sub>@mesoPDA/PEI could directly act as the oxidant of As(III), whereas the reductive catechol group could indirectly oxidize As(III) to As(V) via inducing the production of reactive oxygen species. And indirect oxidation of catechol was the main approach for the As(III) oxidation under acidic conditions. Moreover, the electrostatic adsorption of PEI also played an important role in the adsorption of oxidized As(V). Subsequently, with the help of magnetic technology, the separation and recovery of the adsorbent could be realized, significantly reducing the environmental hazards of heavy metal As.

### NUTRITION OF APPLE ORCHARD WITH LIVESTOCK-DERIVED FERTILISERS: DYNAMICS AND LOSSES OF SOIL MINERAL NITROGEN

R. MORELLI <sup>1</sup>, S. ZANONI <sup>1</sup>, D. BONA <sup>2</sup>, D. PRODORUTTI <sup>1</sup>, D. BERTOLDI <sup>1</sup>, A. CRISTOFORETTI <sup>2</sup>, S. PEDO' <sup>1</sup>, R. ZANZOTTI <sup>1</sup>

<sup>2</sup> Edmund Mach Foundation - Research and Innovation Centre, SAN MICHELE ALL'ADIGE (TN), ITALY

Nitrogen is a very influential macronutrient on crop development. Apple orchards require careful fertilisation, without leading to an excess of N that can be harmful, both to the crop and the environment. This study, in cooperation with the Fruit and Vegetable Growers' Association of Trentino, aimed to replace mineral fertilisers with livestock-derived amendments for apple orchard nutrition, while limiting N losses.

A three-year trial was conducted in an apple orchard of Gala in Trentino. In 2021 the field was organised in randomised plots fertilised with mineral fertiliser (once a year), cattle manure and the solid fraction of digestate from cattle slurry (once at start of the trial). The resulting three theses (MIN, MAN, DIG) were compared to an unfertilised plot (CNT). The soil was sampled on the row during the apple's vegetative cycle, the soil solution was collected using lysimeters at 60 cm, the useful depth limit for roots in this soil, and the leaves were sampled during the fruit swelling. The fruits were harvested at commercial ripening.

Both cattle manure and solid digestate ensured a gradual release of available N into the soil, mainly during the phenological phases of the crop's greatest need, even two and three years after supply. The soil mineral N dynamics in MIN followed the rainfall trend and the release of available N only occurred after flowering if the fertiliser distribution was followed by rain. In the third year, heavy rainfall in May caused an excessive release of N into the soil, which caused heavy leaching, demonstrating a sudden release of mineral N leads to nutrient loss and environmental pollution. N losses in the amended theses were comparable to CNT. N in leaves was similar between the fertilised theses and higher than in CNT. The different strategies ensured similar yield between the theses.

Fertilisation with livestock-derived amendments has proven to be the best strategy to ensure N availability over time and reduce the environmental impact.

### THE IMPACT OF CLIMATE CHANGE ON SOIL QUALITY EVALUATION IN ROMANIA IN THE LAST 30 YEARS

B. ROSCA, C.V. PATRICHE, R.G. PIRNAU, I. VASILINIUC

Romanian Academy, Iasi Branch, Center for Geographical Research, Iasi, ROMANIA

The assessment of soil quality in Romania is based on 17 indicators which are describing mainly the climatic conditions, terrain characteristics and soil properties. Among these factors, the most dynamic and with a major impact on the soil quality score are the climatic ones, respectively the multi-annual average value of the air temperature and the average annual amount of precipitation. For this reason and due to the fact that most studies on soil quality use the average values of these parameters from the reference interval 1961 - 1990, our study analyzes the impact of the evolution of average values of temperature and precipitation from the 1990 – 2019 period on soil quality. We used ROCADA database for the reference interval and CHELSA gridded data for the most recent interval along with 15 other previously developed layers which represent the indicators for soil quality assessment. Finally, we analyze the results for each geographical region of Romania both for changes in soil quality classes and soil suitability for different crops. Considering that in the last analyzed interval, the annual air temperature values increased by 0.9 gr C on average, and the amount of precipitation, although it did not register significant changes in terms of quantity, changed in the sense of increasing the number of extreme events, the soil quality class also changed accordingly. The most significant changes are especially the increase of the soil quality score which can change the quality class especially in agricultural areas but also the decrease the suitability score more obviously in orchard areas. By analyzing the results, we find that by only using the new value for air temperature the soil quality score can be drastically changed, and consequently the Romanian methodology needs to be adapted to take into account the new data.

### EFFECT OF LONG-TERM REDUCED TILLAGE ON SELECTED SOIL BIOLOGICAL INDICATORS ON LUVISOLS IN HUNGARY

P.A. NUGROHO <sup>1</sup>, K. JUHOS <sup>1</sup>, N. PRETTL <sup>1</sup>, S. KABALAN <sup>1</sup>, B. MADARÁSZ <sup>2</sup>, Z. KOTROCZÓ <sup>1</sup>

<sup>1</sup> DEPARTMENT OF AGRO-ENVIRONMENTAL STUDIES, HUNGARIAN UNIVERSITY OF AGRICULTURE AND LIFE SCIENCES, BUDAPEST, HUNGARY

<sup>2</sup> GEOGRAPHICAL INSTITUTE, RESEARCH CENTRE FOR ASTRONOMY AND EARTH SCIENCES, BUDAPEST, HUNGARY

For many decades, the soil has been cultivated intensively by machinery called conventional ploughing tillage (PT). Conservation (reduced) tillage (CT), a system that considers the environmental impact, has been introduced to minimize soil deterioration. The effect of long-term tillage experiments with CT and PT on soil biological activities has not been extensively studied in Hungary. A field study to investigate selected soil biological indicators, i.e., permanganate oxidizable carbon (POXC), Glomalin (GLOM), and Mycorrhiza colonization (MYCO), was carried out on Luvisols, Hungary, in a farmland under CT and PT treatments since 2003. POXC and GLOM were measured from the soil at 0-5, 10-15, and 20-25 cm depths during the last three growing seasons, with the crop rotation being maize I, sunflowers, and maize II. MYCO was observed from the root sampled at 0-20 cm depth. The result exhibited that crop rotation, tillage system, and soil depth considerably impacted soil biological indicators. POXC and GLOM concentrations were higher in maize I, followed by sunflowers and maize II. CT application notably increased the POXC and GLOM during the experiments. Regarding the soil depth, POXC was significantly higher at 0-5 cm depth of maize I and maize II and 0-25 cm depth of sunflowers. GLOM was markedly larger only at 0-5 cm depth. Reducing soil disturbance in CT created a more conducive soil environment and minimized the deterioration effect for soil aggregate and plant roots. This circumstance resulted in the number of root colonization in CT being notably higher than PT, 38.9 and 31.1%, respectively. The alteration of soil water content under different tillage practices remarkably influenced the POXC concentration (Pearson correlation coefficient = 0.27). In this study, we also revealed that GLOM concentration was noticeably correlated with POXC concentration (Pearson correlation coefficient = 0.76). Our results represent the development of a more naturally vertically distributed and time-balanced soil biological activity as a result of long-term reduced tillage.

<sup>5</sup> Consiglio Nazionale delle Ricerche, Roma, ITALY

<sup>6</sup> University of Tuscia, Viterbo, ITALY

<sup>7</sup> Consiglio Nazionale delle Ricerche, Firenze, ITALY

Projections of increased wildfire severity, attributed to warming climates and frequent droughts, heighten apprehensions regarding concurrent impacts on soil carbon and nitrogen pools. Such impacts could alter the sizes and mineralization kinetics of these pools, potentially exerting long-term effects on the resilience of forest carbon sinks and the forests' ability to recuperate from disturbances. In this context, we investigated wildfire impact on an area in the Majella National Park and we try to understand if some management could be helpful for improve soil resilience. The studied area has been affected twice by fire. The control area has been chosen considering the similar forest management. In these two areas regular field campaigns for soil sampling and to record soil respiration have been performed in 2022 and 2023 and data from each meteorological station also equipped of sensors recording soil temperature and humidity have been recorded. Two types of replicates were chosen for fire-covered sites, one closed to dead logs (nature-based solution), and another nearby as control without dead logs, in order to understand if unmanaged area could accelerate soil restoration after wildfire. Physical, chemical, and enzymatic analysis have been performed. Moreover, CO<sub>2</sub> emissions from the soil were measured with a chamber system, assessing the rate of CO<sub>2</sub> change in concentration over time. Preliminary processing of environmental parameters reveals an influence on soil respiration, with the seasonal trend showing an increase over time. Notably, soil respiration is higher in the control site than in the post-fire site. Analysis indicates that increasing temperatures act as a limiting factor for soil respiration, revealing valuable insights into the complex dynamics following a fire event. Moreover, fire led to complete or partial burning of organic matter and ash deposition on the soil surface. Thus, the mixing of ash and partially burnt organic materials into the soil altered soil chemistry. However, the impact of fire on soil chemical properties was highly variable and suggested an insight.

### MICROBIAL-BASED STRATEGIES FOR RESTORING SOIL FUNCTION AND ENHANCING PLANT GROWTH IN DRYLANDS

N. MACHADO DE LIMA <sup>1</sup>, F. DADZIE <sup>1</sup>, M. MUÑOZ-ROJAS <sup>2</sup>

#### Affiliations

<sup>1</sup> Centre for Ecosystem Science, School of Biological, Earth and Environmental Sciences, UNSW Sydney, SYDNEY, AUSTRALIA

<sup>2</sup> Departamento de Biología Vegetal y Ecología, Universidad de Sevilla, SEVILLA, SPAIN

Global environmental changes and other anthropogenic impacts are rapidly transforming the structure and functioning of ecosystems worldwide. These changes are leading to land degradation with an estimated 25 % of the global land surface being affected. The need to develop cost-effective large-scale solutions to restore degraded landscapes becomes imperative to preserve biodiversity and achieve ecosystem functionality and sustainability. Soil microorganisms control important ecosystem functions such as nutrient cycling, plant productivity and climate regulation. Thus, microbially assisted conservation and restoration has the potential to reconnect above and belowground dynamics, creating functional ecosystems that are more resilient to climate change impacts. In this research, we (i) assessed the responses of soil microbial communities to disturbance, e.g., severe fire, and extractive activities such as mining, and (ii) developed bioinoculants composed of locally sourced soil bacteria from the rhizosphere and biocrust cyanobacteria, to promote plant growth and soil fertility and enhance ecosystem capacity for global change adaptation. This presentation will showcase some key findings of these studies conducted in contrasting dryland ecosystems (shrubland-grassland in the arid zone, and subtropical/temperate forests). These outcomes include the successful translocation of whole-soil communities for inhibiting weeds, and the effective use of indigenous microbes (rhizobacteria and cyanobacteria combinations) for soil carbon sequestration, nitrogen fixation, and growth promotion of key arid and temperate plant species.

<sup>2</sup> Gembloux Agro-Bio Tech of Uliege, Gembloux, BELGIUM

Quantitative understanding of contributions of soil and fertilization on yield and factors driving yield increases are essential for effective prioritization of research and development. Previous estimates had limitations in distinguishing soil from climate and crop. Here, we distinguish the separate contribution of soil to yield and quantify the contribution of fertilization to soil quality and yield improvements using a comprehensive agricultural dataset comprised of 15 long-term field experiments (>30 years) for soil, climate and yield, which representing main wheat-cultivated areas in China. Key findings include: 1. Chemical fertilizers notably enhance contribution of soil on wheat yield gains, an annual yield gains rate of 52.2 kg ha<sup>-1</sup> yr<sup>-1</sup>. 2. Contribution of soil on yield nearly doubles when organic manure or straw is added to chemical fertilization, compared to using chemical fertilizers alone. 3. Regional differences exist in how fertilization improved soil quality and contributes to yield gains. These findings underscore the vital role of soil quality in wheat yield, advocating for integrated approaches that combine chemical fertilizers with organic materials to boost soil health and crop productivity.

### BRAZIL'S CONTRIBUTION TO THE STUDY OF ANTARCTIC SOILS: 22 YEARS OF RESEARCH

M.R. FRANCELINO, C.E.R.G. SCHAEFER, E.I. FERNANDES FILHO

Universidade Federal de Viçosa, Viçosa, BRASIL

Antarctic soils have unique characteristics and are directly influenced by the different environments existing in ice-free areas, which range from glacial to periglacial conditions. Knowledge of the pedological particularities of these environments can even contribute to monitoring climate change in that region. One of the first studies of Antarctic soils carried out by Brazilian researchers was that of Kuzmann et al. (1998), who evaluated the mineralogy of soils on King George Island. From 2002 onwards, a new stage of soil studies in the Maritime Antarctic region began, with the beginning of the activities of soil scientists from the University of Viçosa (Brazil). The objective of this work was to present the 22 years of contributions by Brazilian researchers to the study of Antarctic soils. The scientific production considered the terms "Soils" and "Antarctica" and was analyzed using bibliometric approaches, over a period of 10 years. Other actions were also analyzed in order to evaluate their impacts on studies in relation to this theme. As a result, soil maps have already been created on detailed scales covering more than 14 thousand hectares. More than 600 profiles have also been described, which allowed the creation of a soil bank with more than 3,000 samples, which is perhaps the largest soil repository in that region. This group is currently the one that publishes the most articles related to this topic, in addition to having already installed 30 soil humidity and temperature monitoring sites in different parts of Peninsular Antarctica.

Increasing soil organic carbon (SOC) content is vital in areas already fragile and prone to degradation such as drylands in order to maintain healthy soils able to provide ecosystem services. In such areas the aridity limits plant growth and litter inputs as well as soil organic matter (SOM) decomposition. Even if the SOC sequestration rate is low, dryland soils exhibit a high potential of SOC sequestration being far from saturation. In such scenario, the adoption of sustainable land management (SLM) practices in the long-term may reverse the ongoing trend toward degradation. Among them the incorporations of pruning residues to the soil is proved to be successful in enhancing SOC stocks. In addition, the quality of residues is also relevant in driving SOM processing, mineralization and stabilization.

We evaluated the effect of the incorporation of carbon from pruned prickly pear cladodes to the same crop soil (0-30cm). Furthermore, we investigated its distribution in the particulate organic and mineral associated organic matter fractions that as known differently contribute to the stabilization of SOC. The <sup>13</sup>C isotope signature of the *Opuntia ficus-indica* (L.) Mill, which is an obligate CAM plant, was used to identify its contribute to SOC stocks. Two adjacent cactus plantation located in southern Sicily treated with different residues application rates in the last 10 years, were used. The analysis was part of the measures of adaptation investigated by the project Desert-Adapt (LIFE16 CCA/IT/000011) in areas under desertification risk.

### EFFECTS OF COVER CROPS AND NITROGEN FERTILIZATION ON SOIL PHYSICAL PROPERTIES, CARBON AND NITROGEN FRACTIONS, AND WINTER WHEAT YIELD IN THE CHINESE LOESS PLATEAU: A 4-YEAR FIELD EXPERIMENT

J. WANG, C. YANG, S. ZHU

Northwest University, Xi'an, CHINA

Cover crops (CCs) have great potentials to improve soil quality. However, the impacts of CCs as combination with nitrogen fertilization on soil physical properties and aggregated-associated carbon (C) and nitrogen (N) fractions are still not clear. A 4-yr field experiment including CCs with different species [soybean monoculture -SB, Sudan grass monoculture-SG, a mixture of both-SS, and no cover crop-CK] and different N fertilizer rates (NR) [0, 60, and 120 kg N ha<sup>-1</sup>] was conducted under winter wheat on the Loess Plateau of China. Soil physical properties and C and N fractions in bulk soils and aggregates were evaluated at 0-10, 10-20, and 20-40 cm depths. The CC, NR, and their interaction (CC×NR) had significant effects on soil BD, aggregate size distribution and stability (MWD), and C and N fractions. Compared to CK, SB and SS improved soil physical properties especially at 0-10 cm. Additionally, the incorporation of CCs significantly increased the proportions of > 5 mm aggregates and C and N fractions in both bulk soil and aggregates, especially at 0-10 and 10-20 cm depths. Soil physical properties improved more with N60 while the C and N fractions in both bulk soil and aggregates increased more with N120. The correlations between the proportion of macro-aggregates and soil C and N fractions at 0-10 and 10-20 cm indicated the positive effects of CCs on improving soil structure and fertility simultaneously. Aggregated-associated C and N fractions decreased firstly and then increased with the reduced aggregate size, and were higher in micro-aggregates than in other size classes. Compared with that in NO-CK, wheat yields increased by 98.7% in N60-SB. Taken together, the incorporation of SB residue was the best management practice for winter wheat yield and soil fertility under the reduced N fertilization.

We explored how temperature impacts soil respiration rates on rhizospheric soils from *Anacardium excelsum* and *Gliricidia sepium* trees that were exposed to a microbial decomposition process after deforestation. The objective was to determine the maximum ( $R_{max}$ ) and field capacity ( $R_{fc}$ ) respiration rates in soils sampled at the rhizosphere of both tree species. CO<sub>2</sub> emissions were evaluated during soil drying, modelled by a third-degree polynomial function. At 20° and 30°C, *A. excelsum* presented a maximum value of CO<sub>2</sub> emissions at a lower soil-water content than field capacity, as expected. However, this behaviour was only observed at 20°C for *G. sepium*.  $R_{max}$  and  $R_{fc}$  values at 20°C were lower than at 30°C for each species, while at 30°C  $R_{max}$  values of *A. excelsum* were higher than those observed for *G. sepium*. Quantifying the CO<sub>2</sub> emitted during soil drying between  $R_{max}$  and  $R_{fc}$  ( $R_{maxfc}$ ), it was observed that  $R_{maxfc}$  values at 20°C were higher than at 30°C. Remarkably,  $R_{maxfc}$  values at 20°C emitted for *G. sepium* soils were higher than those observed for *A. excelsum* at this temperature. Increments on  $R_{maxfc}$  values were correlated to  $t_{maxfc}$  values or the time of soil drying required to change soil-water contents between  $R_{max}$  and  $R_{fc}$ . No correlation was observed between  $R_{maxfc}$  and  $W_{maxfc}$  or the water retained in soils between  $R_{max}$  and  $R_{fc}$ . Globally,  $t_{maxfc}$  values at the rhizosphere of *G. sepium* and *A. excelsum* at 20°C, was 30 and 20 times higher than those observed at 30°C, respectively. The inclusion of time as a key variable of soil organic matter (SOM) decomposition provides a different vision of soil respiration studies, which usually are focused on specific soil-water contents, such as field capacity or similar values. However, the CO<sub>2</sub> emissions from soils are dynamic, and depend on both water and nutrient availability. The correct quantification of CO<sub>2</sub> released to the atmosphere requires an arithmetic integration of the function that describes SOM decomposition curve over time.

### SOIL C DYNAMICS IN A 45-YR CHRONOSEQUENCE OF GRASSLAND RESTORATION FROM DEGRADED CROPLANDS

P. SOUZA ALONSO<sup>1</sup>, B. OMIL IGNACIO<sup>1</sup>, V. PIÑEIRO<sup>2</sup>, N. BARROS<sup>3</sup>, J. CAMPO<sup>4</sup>, A. MERINO<sup>1</sup>

<sup>3</sup> Department of Applied Physics, University of Santiago de Compostela, SANTIAGO DE COMPOSTELA, SPAIN

<sup>4</sup> Institute of Ecology, National Autonomous University of Mexico, Mexico City, MEXICO

The establishment of temporal or permanent grasslands is postulated as a sustainable opportunity for soil restoration and increasing C sequestration in soils degraded by intensive agricultural management. This transformation involves the recovery of soil organic carbon (SOC) and a whole range of physicochemical and biological properties. Besides, the turnover rate of SOC is highly determined by the distribution and quality of the soil organic matter (SOM) in the different soil physical fractions. Here, we evaluated the accumulation and evolution of SOM quality after a chronosequence (45 years) of grassland reclamation from abandoned croplands in a humid temperate area (Galicia, NW Spain). Topsoil samples were subjected to physical fractionation to assess the distribution of free particulate OM (POM) and mineral associated OM (MAOM). SOM quality was characterized by <sup>13</sup>C NMR spectroscopy and thermal analysis (DSC/TG).

Our results indicated that deforestation and intensive cultivation entailed the loss of a significant 80 % of the C stored in the upper mineral soil (up to 30-35 cm). The POM was almost depleted, MAOM underwent significant losses (>40 %) and all OM compounds -including aromatic C- were affected. The large loss of MAOM can be attributed to the low specific surface soil area and to the labile (biodegradable) nature of the OM in this fraction. After 45 years, grassland conversion recovered a notable 68 % of the C lost in the mineral soil (mainly as MAOM), at an annual rate of 1.25 Mg C ha<sup>-1</sup>. Our findings showed that the persistence of long-term OM depends on how strongly organic compounds are adsorbed onto mineral surfaces (i.e. the specific surface area) and the biochemical nature of OM compounds. In our study, appropriate plant-soil management favoured the replenishment of the MAOM, and this fraction was an active pool in terms of C storage and biochemical quality. This study served to test current theories about changes in soil C fractions due to land use changes and soil-plant management.

### USE OF AGRICULTURE AND URBAN RESIDUE TO IMPROVE SOIL FERTILITY

E. DEMIRAJ<sup>1</sup>, E. DOÇAJ<sup>2</sup>

<sup>1</sup> Agricultural University of Tirana, Tirana, ALBANIA

<sup>2</sup> GFA Consulting Group, Hamburg, GERMANY

One of the best practices to increase soil fertility by also mitigation the effect on climate change and by biomass and energy recovering is the composting process of biodegradable organic waste produced from urban and agricultural sectors. It is a profitable model for various plant and soils, from residential bins to large agricultural farms. In recent years, a local project has been implemented in central region (Elbasan) of Albania, where a large amount of organic agricultural waste originates. The material that was collected during a one-year project implementation was originated from Urban Gardens (UG), Urban Waste (UW), Sport Ground Grass Waste (SGGW), Tabaco Waste (TW) with an amount of about 208.3 Mg from which about 13.5 Mg. As a result, the C/N ratio of the compost which was treated with seven stages was 22:1 which can be very effective in urban and rural use. The combination of the crop residue and urban green waste result to be a valuable practice to reduce the urban and agriculture waste volume and valorize them as part of circular economy.

## 4. Soil health in achieving the Sustainable Development Goals 4.30 133622 - Soil Organic Matter Stability as Key Driver to Soil Carbon Sequestration

### EXPLORING SOIL ORGANIC CARBON PERSISTENCE FOR SUSTAINABLE LAND MANAGEMENT PRACTICES: A THERMAL ANALYSIS APPROACH

J.M. ZENNER<sup>1</sup>, J.H.T. ZETHOF<sup>1</sup>, T.F. RITTL<sup>2</sup>, K. SCHÜTZENMEISTER<sup>1</sup>, H.F. JUNGKUNST<sup>1</sup>

<sup>1</sup> iES Landau, RPTU Kaiserslautern-Landau, Landau, GERMANY

<sup>2</sup> Norwegian Centre for Organic Agriculture (NORSØK), Tingvoll, NORWAY

To ensure the sustainability of an approach to maintain or increase soil organic matter, we need to understand the particularities of various soil organic carbon (SOC) fractions and their response to alterations in soil management practices. Diverse methods of SOC fractionation have been used to isolate and study SOC. Recently, soil physical fractionation has regained popularity due to its simplicity. Soil physical fractionation divides the soil in two main pools, particulate organic matter (POM) and mineral-associated organic matter (MAOM). Yet, the biochemical quality and therefore persistence of the SOC present in these two fractions remain unknown. SOC thermal fractionation provides detailed insights into composition, turnover rates, and stability mechanisms, crucial for advancing sustainable land management practices. This study aims to investigate the relationship between thermal stability and SOC persistence in bulk soil, in the POM and the MAOM fractions – emphasizing the necessity for rapid, precise, and affordable methods. To do so, we will establish a standardized thermal method for determining SOC persistence, comparing thermogravimetry, differential scanning calorimetry and a multiphase carbon and moisture determinant to explore commonalities in addressing SOC persistence. For that, a wide range of soils collected from multiple locations with various land use will be analyzed.

### STABILIZATION OF ORGANIC MATTER BY SHORT-RANGE ORDER MINERALS CAN BE ENHANCED BY THE ACTION OF EARTHWORMS

M. CONTIN <sup>1</sup>, C. ZANUSO <sup>1</sup>, S. ANDRI <sup>2</sup>, E. PELLEGRINI <sup>1</sup>, M. DE NOBILI <sup>1</sup>

<sup>1</sup> Department of Food, Agriculture, Environmental and Animal Sciences, University of Udine, Udine, ITALY

<sup>2</sup> Harpo s.p.a., Muggia, ITALY

Reducing loss of organic matter from soils and growing media is a great challenge for mitigation of climate change's effects. The main strategy to maintain carbon storage in soils by increasing C inputs, is becoming increasingly difficult, as a consequence of increased mineralization of amendments with warming temperatures. Reducing mineralization rate may be the key to sustain organic matter levels. Organic matter is stabilized in soil either physically and chemically through interactions with the mineral particles. In fact, soils containing clay-size short-range order minerals have much higher C content than other soils in the same environment. The extraordinary capacity of these minerals to stabilize organic matter may be utilized in the preparation of growing substrates. To this end, facilitating the contact and interactions of added organic matter and minerals is of critical importance. It is well known that earthworms are main agents in the formation of organo-mineral aggregates.

Our work aims to assess the capability of earthworms in fostering the interactions of added organic matter to short-range order minerals and hence to its stabilization.

To this purpose, in order to verify the stabilization of added organic materials to minerals we carried out a physical partition of SOC based on densitometric fractionation at the beginning and after 90 days of aerobic incubation of synthetic soils in the presence and in the absence of red earthworms (*Eisenia Andrei*). Soils were prepared with five mineral mixtures obtained from grounded rocks, and tested for their content of low ordered minerals either by oxalate-acid extractions and by FT-IR spectroscopy. Compost from urban waste and woodland litter were added to the minerals and incubated in controlled conditions.

Preliminary results show that carbon dioxide (CO<sub>2</sub>) evolution from soil is significantly affected by the different type of mineral substrates and organic matter sources. Earthworms initially accelerate the mineralization rate of organic inputs, but on the medium- long-term a significant reduction of CO<sub>2</sub> emissions has been observed.

<sup>2</sup> UNIVERSIDAD MIGUEL HERNÁNDEZ, ELCHE, SPAIN

<sup>3</sup> IRNAS-CSIC, SEVILLA, SPAIN

Easily Extractable Glomalin (EEG) is a type of soil organic matter believed to contain mostly glycoproteins produced by mycorrhizal fungi. EEG impacts various soil ecological functions, particularly related to soil aggregation formation, stability and water repellence. Here, analytical pyrolysis (Py-GC/MS) is used to investigate EEG's molecular composition. A detailed description of the chemical composition of EEG is provided from samples extracted from soils under pine and shrubs, either impacted or not by forest fires and collected at different times. 139 compounds were identified and grouped based on their probable biogenic origin. The composition of samples collected from different plant covers and at different times of the year remained similar, whether affected by a forest fire or not. The chemical composition of EEG is mostly dominated by lipids, aromatic compounds, steranes, and hydro-aromatics, with a remarkable abundance of compounds from plant origin. Although contributions from microorganisms to EEG are not ruled out, its structure does not resemble that of glycoprotein. Instead, due to its high aromaticity and recalcitrant structure, it resembles that of humic acids. Minor changes in EEG structure can indicate environmental disruptions, such as those that occur after a wildfire. The EEG soil organic fraction is a relatively stable and heat-resistant material in nature, as long as soil temperatures remain below 200-250°C.

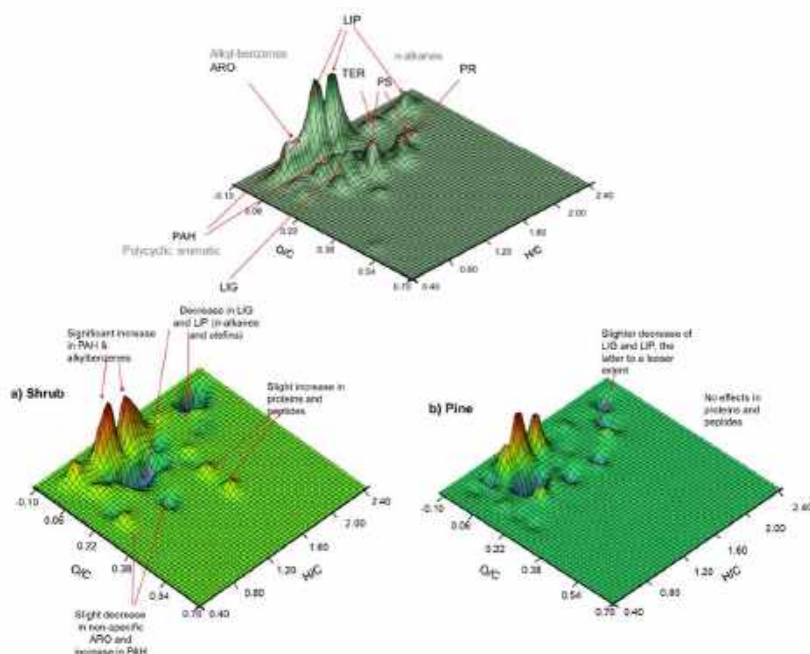

Figure 1. 3-D van Krevelen diagrams showing EEG average composition. Above: average chemical composition. Below: diagrams showing the effect of fire (control plots minus fire affected plots) for EEG extracted from soil under a) shrub and b) pine vegetation. Aromatic compounds (ARO), lignin-derived (methoxyphenols) (LIG), lipids (LIP), polycyclic aromatic hydrocarbons (PAH), protein-derived (PR), polysaccharide-derived (PS) and terpenes (TER).

### RECOVERING OF SOIL ORGANIC MATTER AND ASSOCIATED C AND N LABILE FRACTION AT DIFFERENT TREE SPECIES INFLUENCE IN REGENERATED FOREST ECOSYSTEMS AFTER MINING AND FIRE DISTURBANCES

B. WOS<sup>1</sup>, A. JOZEFOWSKA<sup>2</sup>, M. CHODAK<sup>3</sup>, M. PIETRZYKOWSKI<sup>1</sup>

<sup>1</sup> University of Agriculture in Kraków, Faculty of Forestry, Department of Ecological Engineering and Forest Hydrology, Krakow, POLAND

<sup>2</sup> University of Agriculture in Kraków, Faculty of Agriculture and Economics, Department of Soil Science, Krakow, POLAND

<sup>3</sup> AGH University of Science and Technology, Department of Environmental Management and Protection, Krakow, POLAND

The labile fraction of soil organic carbon (LSOC) plays a vital role in recovering soil properties and quality. The aim of study was compare labile C and N fractions, including microbial biomass C (MBC), cold-water-soluble C (WSC), water-soluble N (WSN), hot-water-extractable C (HWC), hot-water-extractable N (HWN), particulate organic carbon (POC), and particulate organic nitrogen (PON) in post-mining, post-fire, and undisturbed soils under different tree stands (Scots pine, common birch, and black alder). Nearly 30 years after the disturbance, post-mining soils were characterized by lower soil organic carbon (SOC) and total nitrogen (TN) as well as their labile fractions compared to those of post-fire and undisturbed soils. Disturbed soils had less stable SOC than undisturbed soils. Compared to the post-fire site, the higher proportion of WSC in SOC in post-mining soils suggests higher SOC turnover and leaching potential during primary succession compared to secondary succession. The post-fire soils had a similar SOC stock to undisturbed soils but differed in the C and N labile fractions stock. Post-fire soils were characterized by higher POC stocks due to charcoal admixture and lower WSN, HWC, and HWN fractions than undisturbed soils. The studied tree species differently affected the recovery of SOM properties after disturbances. Post-mining soils under alder had higher SOC, TN, and labile fractions (except MBC) than soils under birch and pine cover. However, this was not true for the post-fire site, where only WSN was higher under the alder. The soils under birch stands had the highest MBC stocks across all sites. The soils under pine had less stable SOM than those under birch and alder, which may accelerate podzolization processes. Results indicate a longer time for the recovery of C and N pools during primary succession than in secondary succession on sandy soils. Alder, as phytomelioration species that increases the C and N pools in post-fire sites, has limited usefulness.

<sup>4</sup> University of Belgrade, Faculty of Forestry, Belgrade, SERBIA

Microplastic (MP) pollution is recognized as one of the biggest environmental problems due to multiple direct and indirect negative impacts on the environment. Existing research indicate that the presence of MP in the soil affects the organic matter cycle and the energy flow of terrestrial ecosystems, thus also the global production of CO<sub>2</sub>, climate, plant communities, crop production and biodiversity. There are even fewer studies dealing with the impact of MP on forest soil ecosystems. One of the first researches of the MP in the soil on the territory of Serbia is currently underway and is being carried out within the project Evaluation of the Microplastic in the Soils of Serbia - EMIPLAST - SoS. The research aimed to assess the impact of MP on soil's main chemical, physical and biological properties by comparing polluted and non-polluted forest sites in the three largest alluvial plains in Serbia – Danube, Sava and Morava. Statistically significantly higher values of electrical conductivity and pH were measured in samples from polluted localities compared to unpolluted ones; while C, N and CEC were measured significantly higher in samples from unpolluted sites. Particles > 0.02 mm were significantly higher in all samples from polluted sites compared to non-polluted. Changed environmental conditions have an effect on the decomposition by soil microorganisms. Estimates of potentially mineralizable carbon and mineralization rate are statistically significantly higher at polluted sites compared to unpolluted ones in all three alluvial plains. These results support the viewpoints that can be found in the literature, namely that the presence of MP in the soil affects the cycle of organic carbon and CO<sub>2</sub> emissions. Also, differences in estimates between polluted and unpolluted forest sites indicate that microbial communities may be using MP particles as an additional food source. In order to establish the level of the impact of MP on soil properties and microbial activity in the longer term, the study is ongoing.

The global use of plastic has rapidly increased since the 1950s, becoming an indispensable part of human production and life. In 1950, the global plastic production was 1.5 million tons, but by 2020, it had grown to 367 million tons. Increased use, poor management, problems with disposal and removal of plastics from the environment have increased the pollution of soils by plastics or microplastics (MP; plastic particles smaller than 5 mm) in recent decades.

One of the most significant inputs of plastics into the soil environment is through agriculture. Agricultural plastics, various plastic materials and products, play a crucial role in modern agriculture by providing solutions for crop protection, resource conservation, and overall efficiency. Based on the studies conducted so far, researchers have raised general concerns about the long-term impact of plastic residues on agricultural land and have concluded that soils are an important sink for MP. Given the ubiquity of MP in soils, the high levels of MP and the potential for the current situation to worsen, further research into the impact and transport of MP in soils is of big importance. It is therefore crucial to investigate the effects of MP, i.e. their extent, type and content, on the physical properties of soil, especially in relation to water, which often determines the transport, adsorption and degradation of contaminants in soils and agroecosystems.

The type, size and content of MP have different effects on soil physical properties. Research has shown that MP affects soil density, hydraulic conductivity, water retention capacity and water repellency. Therefore, the aim of the study was to assess the impact of different MP types and contents on selected soil physical properties in soils with different textures. During an 8-month pot experiment we monitored soil water content changes during wetting-drying cycles. Different soil physical changes were monitored, analysed and compared.

**Keywords:** microplastics, soil physical properties, wetting - drying cycles

### MIGRATION BEHAVIORS AND ENVIRONMENTAL RISKS OF PHTHALATE ACID ESTERS AND MICROPLASTICS FROM AGRICULTURAL FILMS

F. WANG

Institute of Soil Science, Chinese Academy of Sciences, Nanjing, CHINA

Plastic films have become an integral part of fruit and vegetable production systems, but they are a source of phthalic acid esters (PAE) and microplastics that pose health risks to humans. Despite recent efforts, the issue of the migration and environmental fate of phthalic acid esters and microplastics derived from agricultural films remains unresolved and therefore still open for investigation. Here, we analyzed 50 agricultural films and found that their PAE concentrations varied widely from 2.59 to 282,000 mg/kg. Bis(2-ethylhexyl) phthalate was found in most agricultural plastic films analyzed, especially those made of polyvinyl chloride and metallocene polyethylene. Under the influence of sunlight and other environmental factors, agricultural plastic films age and deteriorate, releasing PAEs and turning into microplastics. Even biodegradable plastic films may not fully degrade depending on environmental conditions, and micro- and nano-plastics derived from them may persist in the environment. These microplastics often have their surfaces charged by weathering, mechanical crushing, and other environmental processes. In this regard, we quantified the fluorescence intensity of positively and negatively charged microplastics on nine different soil types to investigate the mechanism of interaction between microplastics and soil. The results showed a strong affinity for microplastic attachment to the soil, and electrostatic interactions and physical entrapment were the dominant mechanisms for microplastic attachment to the soil. In another study, we found that plants could take in microplastics through their roots and then move them to their above-ground parts. Microplastics could also get into plant leaves through stomata and cuticles. Considering these findings, we propose: (1) either rethinking the manufacturing process to reduce the concentration of PAE in agricultural plastic films or warning buyers and producers about potential risks, (2) strengthening the recycling and reuse of agricultural film waste to reduce environmental plastic pollution, and (3) finding ways to increase the rate of degradation of degradable agricultural films so that complete degradation can be achieved and microplastic pollution can be avoided.

<sup>2</sup> Department of chemical science, University of Naples Federico II, Naples, ITALY

Plastic mulches are widely used in agriculture but their mismanagement produces microplastics (MPs) impacting the soil quality. The evaluated if the presence of MPs in soils caused changes in element availability and in their translocation and accumulation in spinaches (*Spinacia oleracea* L.). To achieve the aim, conventional (P) and bioplastic (B) MPs were added at 0.5%, 1% and 2% in soils where spinaches were grown. The mesocosm trial was performed in 35 pots (5 control, 5 for each percentage of B and P). Al, Ca, Fe, K, Mg, Mn, Na V and Zn were measured in soils (available fraction), roots and leaves; then translocation (TF) and bioaccumulation (BF) factors were calculated. Fe and Zn were significantly higher, Na and V significantly lower in 2%-P than in control soils. In B soils, Fe, Mn, Na, V and Zn were significantly lower at all the concentrations, Ca and Mg only at 1% than in control. Regardless of the treatment, TF>1 was calculated for all elements, excepted Ca. Particularly, Fe, Mn, Mg, V and Zn were significantly less accumulated in roots of P than control. Conversely, all elements, excepted Mg, were significantly more accumulated in roots of B than control. Regardless of the treatment, TF>1 were calculated for K, Mg, Mn, Na and Zn, and TF<1 for Al, Ca, Fe and V. For P treatments, K, Mg, Mn and Na were significantly more translocated to leaves and Zn less translocated than in control. For B treatments, Mg and Mn were significantly more translocated and K, Na and Zn less translocated than in control. In conclusion, the presence of both B-MPs and P-MPs affected soil element bioavailability, and element accumulation and translocation in spinach, although different trends were observed according to single element.

<sup>2</sup> Spotteron GmbH, Vienna, AUSTRIA

In Europe, about 50 million tons of plastic are produced per year out of which ca 40% is processed into packaging (Plastic Europe, 2022). Packaging often ends up in landfill or in the environment after only a short or single use. Unfortunately, recycling is often inadequate, contributing to only about 10% of the European demand for plastic being met by recycled plastics (Plastics Europe, 2022). Large amounts of plastic end up in the oceans, accumulating as garbage patches and washing up on shores. However, the amounts of plastics that end up in soils is not precisely known. Scientific studies have concluded that 4 to 32 times as much plastic ends up in soils as in water bodies (Horton et al., 2017). In addition, little is known about what types of plastics enter the soil environment, and in what proportions.

The Soil Plastic App allows citizens to input observations of visible plastics and their characteristics, with a strong focus on agricultural plastics, on soils and enable to monitor the change of plastics in soils. The App runs on the citizen science Spotteron Platform and is available for iOS, Android and as a web application. This way, observations can be entered anywhere on the globe and anytime. Since December 2022, citizens have already made over 22.000 plastic observations in the SoilPlastic App. The first set of validated Austrian citizen observations between beginning of April 2023 and end of July 2023 resulted in ca 6000 observations, as part of the Austrian Citizen Science Award Project Bunter Boden. This presentation will present the first results from Austria and discuss the potential of SoilPlastic App in observing change of plastics in soils.

<sup>2</sup> Dipartimento di Scienze e Tecnologie Agrarie, Alimentari Ambientali e Forestali - DAGRI, Università di Firenze, Firenze, ITALY

A device based on elutriation, a principle commonly used in sediment processing, was used to extract microplastics (MPs) from agricultural soil in Italy treated with urban compost since 2005. The extraction procedure was evaluated for both the entire soil, including the skeleton, and the fine earth (< 2 mm). The weight, count, and characterization of MPs were determined using FTIR photoacoustic spectroscopy (FTIR-PAS). The mass and number of MPs bits recovered (> 34 µm) were found to be in the same order of magnitude as those found in other soils. The main polymers identified were polystyrene, polyethylene, and polypropylene.

The study identified two main issues: firstly, the sieving procedure used to separate particles greater than 2 mm also retained lighter particles, subtracting them from the elutriation process. Secondly, the presence of soil stable aggregates was found to be responsible for the unexpected presence of MPs remaining in the device. To address these issues, two possible solutions were suggested: firstly, sampling the entire soil, including the skeleton, where the size of the largest particles size can be manageable. Secondly, breaking, before elutriation, the soil aggregates through ultrasonication and dispersion to release the plastics trapped within them.

This work is particularly relevant because sampling techniques, extraction methods, analytical procedures, and even units of measure for MPs in soil are not standardized due to the complex nature of soil as a matrix.

Pollution by microplastics in European soil is a relevant issue. The lack of knowledge of this problem is mostly because most of the studies are done in aquatic ecosystems, and just recently, terrestrial environments gained more attention. Agricultural soils are mentioned as tanks of microplastics. The complexity of detecting these little particles, no clear pathway of different types of microplastic from soil ecosystem to plant, animal, and humans, and unknown true effects on soil make prognosis imprecise, yet frightening.

In this literature review, we systematically compare last decade's studies on microplastic pollution in different Baltic Sea region countries (Denmark, Sweden, Finland, Estonia, Latvia, Lithuania, Poland, and Germany). The main focus goes on identifying the recent knowledge level and status quo of the mentioned research, mapping potential pollution sources, and identifying hotspots to get a wider view of possible ecological risks in the future of Europe.

After performing the analysis, we observed that there is a lack of information on the regional release of microplastics to agricultural soils, no clear classification of factors affecting the concentration of microplastics in soil, and no observations of possible effects on the environment in the target regions.

### EVALUATION OF POTENTIAL ENVIRONMENTAL IMPLICATIONS OF ANAEROBIC DIGESTION OF BIOPOLYMERIC FILMS BY LCA

N. MONTEGIOVE<sup>1</sup>, R. PETRUCCI<sup>2</sup>, D. PUGLIA<sup>2</sup>, G. GIGLIOTTI<sup>1</sup>, D. PEZZOLLA<sup>1</sup>, L. TORRE<sup>2</sup>

<sup>2</sup> Department of Civil and Environmental Engineering, University of Perugia, UdR INSTM, Terni, ITALY

The rise in environmental contamination resulting from plastic waste disposal led to the advancement of novel technologies for the production of bio-based materials. Hence, the use of biodegradable polymers in the food industry has witnessed a significant surge. Within this framework, the use of polylactic acid (PLA) and polybutylene succinate (PBS) containing cellulose nanocrystals (CNCs) extracted from hemp fibers has been considered. This study investigated the whole Life Cycle Assessment (LCA) of different biopolymeric films, focusing on the related production phase and their potential end-of-life scenarios, regardless of the film durability (i.e. a single-use packaging) and barrier performance, to counteract possible soil health threats.

In particular, PLA, PLA\_20PBS (PLA/PBS blend), and PLA\_PBS\_3s-CNC (PLA/ PBS blend + 3% CNCs) films were examined. The investigation considered a batch anaerobic digestion (AD), at 52 °C, using municipal waste-derived digestate as inoculum. Cellulose served as a reference material. The AD was monitored over 28 days, revealing that cellulose-containing reactors exhibited enhanced biogas production, emphasizing its intrinsic biodegradability and suggesting an inhibitory effect of the synthetic biopolymeric components. The inhibition could result from their complex structure and recalcitrant nature, hindering the action of microbial consortia responsible for biomass degradation and methanogenesis.

The LCA analysis focused also on the multifaceted environmental implications of integrating biopolymers into the production of renewable energy and digestate to be used as an organic fertilizer after the composting. Remarkably, the PLA\_PBS\_3s-CNC formulation showed a slightly higher performance, which can be attributed to the presence of 3% CNCs, confirming the positive effect in terms of reduced environmental impact.

The enhanced biodegradability and the reduced environmental impact, suggest a potential avenue for optimizing biopolymeric formulations to both mitigate inhibitory effects on AD processes and maximize the use of naturally derived energy sources.

### THE POSSIBILITIES AND LIMITATIONS OF THE AGRICULTURAL USE OF SEWAGE SLUDGE IN THE REFLECTION OF THE AMENDMENT OF EEC DIRECTIVE 91/271

C. NAGY-MEZEI<sup>1</sup>, A. BEZSENYI<sup>2</sup>, I. GYARMATI<sup>2</sup>, L. KARDOS<sup>1</sup>

<sup>1</sup> Hungarian University of Agriculture and Life Sciences, Department of Agro-Environmental Studies, BUDAPEST, HUNGARY

<sup>2</sup> Budapest Sewage Works Pte Ltd., South-Pest Wastewater Treatment Plant, BUDAPEST, HUNGARY

Sewage sludge is a by-product of municipal and industrial wastewater treatment, which is produced in large quantities. It can vary widely in terms of its nutrient content and also its content of substances which are potentially harmful to the nature and human health. The disposal method and end use of the sludge produced during the sewage treatment process may differ depending on the quality and quantity parameters the sewage sludge must meet. From an economic and environmental point of view, the most suitable disposal method for sewage sludge would be to use it as a soil improvement additive (e.g. due to the decrease in the relative phosphorus content of the soil), as opposed to incineration and landfilling, however the inappropriate concentration of some components may limit the agricultural utilization. Most of the harmful substances in sewage sludge are non-biodegradable and persistent, of which micropollutants have received special attention in recent years (e.g. microplastics, active pharmaceutical ingredients), as they can have a harmful effect on the ecosystem and human health even at low concentrations ( $\mu\text{g}/\text{kg}$  dry matter,  $\text{ng}/\text{kg}$  dry matter). The most recent amendment of Directive 91/271 EEC pays special attention to the issue of micropollutants (e.g. the mandatory use of washing machines with microfilters in order to prevent the excessive emission of fibrous microplastics). The directive also deals with the monitoring of micropollutants during wastewater treatment and sludge treatment technologies, however, little is known about the migration and accumulation properties of micropollutants in the sewage sludge-soil system.

### SHALLOW LANDSLIDE IN AGROECOSYSTEMS: THE CASE STUDY OF OLTREPÒ PAVESE VINEYARDS (NORTHERN ITALY)

A. GAMBARANI<sup>1</sup>, A. VERCESI<sup>2</sup>, M. BORDONI<sup>1</sup>, A. GIAROLA<sup>1</sup>, V. VIVALDI<sup>1</sup>, C. MEISINA<sup>1</sup>

<sup>2</sup> Università Cattolica del Sacro Cuore, Piacenza, ITALY

Shallow landslides are a significant environmental problem in all contexts, but for agroecosystems this translates into soil loss and nutrient loss; both factors are extremely important for agriculture and economy. Due to climate change and extreme weather events, these processes are likely to become more widespread, thus leading to significant land abandonment. Another factor affecting shallow landslide concerns soil tillage by agricultural machinery, which, if uncontrolled, can accelerate the development of these processes. Shallow landslides are also dangerous for rural communities because of their rapidity of initiation and development and the lack of warning signs for its detection. The aim of this work is to produce an overview of shallow landslides occurred in different agroecosystems in Italy, with a focus on vineyards. Some shallow landslide inventories were analysed and compared with agricultural land use reported in CORINE Land Cover in the Italian territory. In order to analyse the role of the different agroecosystems and the related slope management technique into shallow landslide triggering the Oltrepò Pavese (Northern Italy) was selected as pilot site. The study area is one of the most important agricultural and viticultural regions in Italy. In the last 15 years, more than 2000 shallow landslides were triggered in consequence of intense rainfall events, with a density of distribution which reached more than 40% of the territory cultivated with grapevines. The work is carried out in the context of a PhD project, financed with PNRR (National Recovery and Resilience Plan) and cofounded by seven municipalities, stakeholders of the project. The final aim of the PhD project is to identify the most suitable, in terms of technical and economical suitability, Nature - based Solutions for the studied area. The scientific research results will be incorporated within the municipal planning tools and rural police regulation in order to prevent shallow landslides.

<sup>3</sup> Dipartimento di Agraria, Università degli Studi di Napoli Federico II, Portici (NA), ITALY

Several research studies investigated the role of weathering processes as predisposing factors of landslides. However, most of them did not consider soils from a pedological point of view, by applying a sampling design able to catch the intrinsic vertical variability through the soil profile. This principle that is common knowledge for soil scientists, is frequently neglected by geologists and engineers. Major findings on this topic were obtained in volcanic soils involved in flow-like landslides in many geographic and climatic contexts, but other soil types have been poorly explored so far. The ongoing project "SOIL SHADES – SOIL features and pedogenic processes as predisposing factors of SHALLOW landslIDES", supported by the Italian Ministry of University, is focused on an integrated multidisciplinary, multianalytical and multiscale approach applied to this purpose in a pilot catchment (Turbolo Stream) of Calabria, S Italy. This area can be considered as representative of other drainage basins in the region and in many other Mediterranean and mid-latitude contexts, based on its geological-geomorphological, pedological and environmental features. Therein we are applying traditional and innovative soil analyses together with geological, geomorphological and geotechnical investigations to assess how soil features, derived from specific weathering and pedogenic processes that modified the original properties of the parent materials through time and hence their rheological behavior, might be responsible for the triggering of shallow landslides. This approach combines field surveys at catchment, hillslope and pedon/soil profile scales (with a special focus on landslide mapping and their relations with different lithologies, landforms, soil types and other geomorphic processes) and a variety of laboratory analyses. We are using remote and proximal sensing techniques, such as drone, electromagnetic induction, electrical resistivity tomography and gamma-ray spectrometry to map the soil spatial variability. Laboratory analyses aim to assess chemical and physical properties, mineralogy, geochemistry, micromorphology, geotechnical and hydrological behavior. This work gives new insights into a deeper comprehension of the mechanisms driving landslides and associated susceptibility, hazard and risk.

### SOILS OF THE NOVEMBER 26, 2022 CELARIO FLOW-LIKE LANDSLIDE AT THE ISCHIA ISLAND (SOUTHERN ITALY)

F. TERRIBILE <sup>1</sup>, A. BASILE <sup>2</sup>, D. CALCATERRA <sup>3</sup>, L. DE VITA <sup>3</sup>, L. GUERRIERO <sup>3</sup>, F.A. MILETI <sup>1</sup>, R. TUFANO <sup>3</sup>

<sup>1</sup> Università degli Studi di Napoli Federico II, Portici, ITALY

<sup>2</sup> CNR ISAFOM, Portici, ITALY

<sup>3</sup> Università degli Studi di Napoli Federico II, Napoli, ITALY

On November 26, 2022, a heavy rain had a significant impact on Ischia Island in Southern Italy, leading to the triggering of numerous very rapid and destructive flow-like landslides. The municipality most affected by this event was Casamicciola Terme, resulting in 12 casualties, the evacuation of over 200 people, and considerable damage. The largest flow-slide occurred in the Celario watershed, initially starting as a small soil slip (approximately 10m<sup>3</sup>) on the top of Mt. Epomeo at an elevation of about 720 m above sea level. The initial slide evolved downslope as a flow-like landslide due to a dynamic liquefaction mechanism of pedogenized ancient debris flow deposits outcropping along the slope. The first flow stage was a debris avalanche while the second flow stage was a debris flow. The downslope evolution of the landslide involved a progressively increasing volume up to a maximum value estimated in about 40,000 m<sup>3</sup>, which moved downslope with a velocity up to 10 m/s.

The current study aimed to approach the above catastrophic landslide through an Earth Critical Zone approach aiming to understand whether soils contributed to the landslide propagation mechanisms. The study was conducted by analysing two soil profiles in two detachment crowns and the two ancient debris sediments. Our findings demonstrate that soils gave an important contribution to dynamic liquefaction and propagation mechanism because their depth and specific physical and chemical properties, especially the high sodium content on the exchange complex; in addition, we demonstrated that pedogenesis is clearly present – possibly as a relict feature also in the debris flow sediments. The study reveals the crucial importance of using an ECZ based approach to analyse landslide risk at territorial scale.

### CAN SOIL INVESTIGATION AND MICRO-TOPOGRAPHY CONTRIBUTE TO UNDERSTANDING OF SINKHOLE FORMATION? A RECENT CASE OF STUDY IN CENTRAL ITALY

F. GENTILI<sup>1</sup>, S. PRIORI<sup>2</sup>, S. MADONNA<sup>2</sup>, S. NISIO<sup>3</sup>

<sup>1</sup> Università degli Studi della Tuscia - Department of Ecological and Biological Sciences, Viterbo, ITALY

<sup>2</sup> Università degli Studi della Tuscia - Department of Agriculture and Forest Sciences, Viterbo, ITALY

<sup>3</sup> ISPRA - Technical-scientific support section management, Roma, ITALY

Sinkhole formation is a complex process that can be influenced by various factors, including physical landscape history and human activities. This study focused on the interrelationships between pedological-morphological elements, and the hydrogeological, geological, and environmental factors that contribute to the development of this geological hazard, emphasizing the importance of interdisciplinary research to comprehensively address the challenges posed by sinkholes in volcanic areas. Specifically, on January 31, 2023, a sinkhole occurred in the Volsini volcanic region in northern Latium, central Italy, at the bottom of the Vepe caldera, which is a small caldera nested within the Latera caldera. The soils of the area are classified as Cambic Phaeozems, developed on lacustrine, marsh, and reworked volcanic deposits. Geological, geophysical, and geochemical investigations were carried out to examine the collapse and the surrounding area to identify potential contributing factors. Soil characteristics and indicators could provide valuable information about sinkhole-prone areas and could be essential for early detection and mitigation of potential hazards. While no specific soil characteristic can definitively predict a sinkhole, certain clues and indicators can raise suspicion and warrant further investigation. Hydrological dynamics play a critical role, but soil texture and structure are also important factors that allow for rapid infiltration of rainfall and control erosion, subsidence, compaction, or settlement. Soil chemistry can help identify accumulation and translocation processes in the lower soil horizons related to water infiltration that may precede collapse development. Similarly, surface features, such as depressions or cracks in the ground, could be signs of ongoing subsurface changes. The area has been monitored using Unmanned Aerial Vehicles (UAVs) since the early stages of the sinkhole's formation and is still being monitored today. The use of UAV photogrammetry has allowed for the reconstruction of the micromorphology of the area at high-detail and to monitor in safety, the sinkhole's dimensions, changes in the water level, the stratigraphy, and the soil horizons along the sinkhole's slope.

<sup>4</sup> 5ECOS Soluções Sustentáveis, Piracicaba

Urban and agro-industrial wastes may be carbon:nitrogen (C:N) ratio and nutrients imbalances, excess sodium, pathogens and heavy metals, which can alter the soil fertility and contaminate the soil-water-plant system. These residues mixed with carbon rich materials, in composting process, can improve its nutritional quality and reduce contaminants. However, the large amount of waste generated and the long time requires to stabilize it can make the large-scale process costly and unfeasible. This study aimed to compare the decomposition of wastes mixture 30:1 C:N ratio, initial water content 50%, in laboratory test and in compost piles, to optimize composting factors. Sewage sludge, food waste and swine manure were mixed separately with tree pruning and grass and incubated in respirometry test at 28°C. Released CO<sub>2</sub> was captured in NaOH solution, measured by electrical conductivity, until stabilization at 85 days, and the data adjusted to the first order equation. Compost piles were built to the dimensions 4.0 (L) x 2.5 (W) 1.5 (H) m, totaling 15 m<sup>3</sup> organic materials, monitored for temperature, water, carbon and nitrogen contents, turned and irrigated for 60 days until final thermophilic phase. Quality parameters and contaminants of final organic composts from both processes were within the limits of Brazilian fertilizer legislation. Decomposition rates under laboratory and field conditions ranged from 20% to 30% (sludge + grass; food + grass) and 30% (sludge + pruning; food + pruning; food + grass) to 50% (sludge + grass swine + pruning, swine + grass), respectively. Decomposition final time was equal to sludge treatments, and twice as fast for food and swine waste and both structuring materials, when composting process was compared to respirometry. It can be observed that recalcitrance of the N-rich residue controls the decomposition process, and the respirometry test proved to be a good tool to scale compost process and costs, as well as to produce organic composts for sustainable agricultural use.

Anaerobic digestion is a promising technology to improve the living standards of rural communities, reduce environmental pollution and promote sustainable development. Apart from biogas, digestate is the other product of the anaerobic digesters and its reuse in agriculture can be as important as biogas in rural households and small farms of Latin America.

According to the UNCCD, there are more than 2 billion hectares of degraded land in the world, of which 14% is in Latin America.

In this context, this study reports the results of a first attempt to use digestate from rural digesters for degraded soil restoration in Colombia. Digestate from anaerobic digester fed with pig slurry and operating under psychrophilic temperature (15°C) was applied daily during 4 months to a degraded soil subjected to intensive cultivation for many years (latitude of 5°51'42.3'N, 72°57'51.6'W Colombia). Digestate produced daily (3 m<sup>3</sup>) was spread uniformly onto all the experimental site and the soil was subjected to no tillage nor cultivation of crops. After 4 months of daily application, the digestate spreading was stopped. During the following months, the experimental site was not used nor for cultivation, nor for grazing. Soils samples (10-20 cm depth) were collected before the start of the experiment (M1), after 4 months of daily digestate application (M2) and after 4 months from the last digestate application (M3).

Following digestate application, soil pH and cation exchange capacity significantly increased. Soil organic C significantly increased (+60% from M1 to M2) and its concentration was stable from M2 to M3. Digestate application enhanced the stable, mineral-protected and recalcitrant pools of C in soil, proving that digestate may effectively increase soil organic C content, improving soil fertility and acting in C storage and sequestration in soil (Figure 1). All plant nutrients analyzed significantly increased after digestate application (N, available P, Ca, K, Mg, Fe, Mn, Mo). No significant threats of heavy metals accumulation were identified after digestate application.

<sup>2</sup> Laboratory of Soil Sciences, Faculty of Biology, Plant Biology, University of Barcelona, Barcelona, SPAIN

Soil is a limited resource and the availability of natural soils for land reclamation and restoration is a serious issue. Moreover, they can be the key for urban areas and industrial agriculture. For these reasons, it is important to prepare technical soils (technosols) by using waste in the framework of circular economy and zero waste promoted by the European union. This type of soils is defined in the WRB as a group that combines soils whose properties and pedogenesis are dominated by their technical origin, and includes soils from wastes. These soils are usually prepared adding inorganic and organic materials. In this sense, the presence of organic carbon can help to mitigate the negative effects of climate change.

To study the presence of organic matter in technosols, an experiment was done with 16 technosols for a short period of cultivation of tomato (three months). These technosols were a combination of several inorganic materials (fine and coarse calcium carbonate gravel -80% volume-) and organic wastes: sewage sludge compost, palm tree leaves, hay straw, and olive tree leaves, and peat (20% volume).

After the short period of cultivation, in the fine earth, the presence of soil organic matter was determined by two methods: Walkley-Black and Loss on Ignition. The results showed that, in general, the technosols made using compost from sewage sludge have more organic matter in the fine fraction. The type of organic matter and the size are key factors for plant nutrition, organic matter decomposition and physical and chemical interactions. Opposite, treatments with hay straw added less organic matter to the fine earth.

<sup>3</sup> Desertification Research Centre, Università degli Studi di Sassari, SASSARI, ITALY

Increase in the generation of solid waste and sewage sludge is linked to population growth and sustainable development, motivating investigations aimed at transforming this “waste” into a product, which is rich in organic and mineral matter. In-depth studies are essential to ensure safe use and minimize environmental risks. The main objective of the study was to carry out a systematic review following the PRISMA protocol, crucial for rigorous and transparent literary reviews. The protocol provides essential methodological guidelines for consistent documentation in systematic reviews. The research involved a systematic search on the Scopus and Web of Science platforms, using the keywords (('sewage sludge' OR 'byproduct'), AND ('urban ground' OR 'landscape' OR 'soil remediation' OR 'forestry')). The dataset obtained in this phase totaled 7.625 records. Strict inclusion criteria were applied: English-only documents, accepted and published articles, thematic area of interest, articles published from 2013 to August 2023, and studies presenting quantitative data. Duplicate articles were excluded. After these steps, 90 articles were carefully selected as eligible. So far, it can be concluded that there has been a significant increase in the number of studies, particularly in the last 6 years, which accounts for 78.9% of the total number of studies identified. It is observed that 83.3% of the studies are concentrated in America, Europe and Asia, with Brazil and China having the greatest representation, totaling 40% together. 96% of the articles compared sewage sludge, control, or other raw materials, providing a robust dataset for analysis. In this context, it can be stated that, so far, the objectives outlined have been achieved, as the proposal aims to analyze the use of sewage sludge in forestry and landscape species and in soil recovery. Around 59% of articles address these specific areas. The next phase will be to carry out a meta-analysis of the data contained in the articles in order to verify statistical correlations between the investigated elements.

#### FROM WASTE TO WEALTH: ENHANCING SOIL HEALTH WITH NOVEL SOIL IMPROVERS - THE WASTE4SOIL PROJECT

A. VERA <sup>1</sup>, Y. WANG <sup>2</sup>, E. HUERTA-LWANGA <sup>2</sup>, F. BASTIDA <sup>1</sup>

<sup>1</sup> Department of Soil and Water Conservation and Organic Waste Management, CEBAS-CSIC, MURCIA, SPAIN

<sup>2</sup> Soil Physics and Land Management Group, Wageningen University & Research, WAGENINGEN, THE NETHERLANDS

The Waste4Soil project tackles the urgent need for sustainably managed food processing residues (FPR) by developing innovative recycling pathways to convert them into soil improvers. Adopting a holistic, circular, and multi-actor approach involving stakeholders across the food chain, the project aims to close specific loops, including nutrients, organic matter, and water, at the regional scale (involving 28 partners from 9 European countries and Switzerland). Key objectives include optimizing FPR collection and understanding, developing standards to support circular food systems and soil health, formulating eco-friendly soil improvers, and engaging food system actors and citizens in a circular economy.

To achieve these goals, a standardised Evaluation Framework will enable stakeholders to assess their progress towards FPR circularity, while Living Labs across Europe will facilitate collaborative research and innovation. The project's work plan, organised into eight Work Packages, encompasses activities ranging from knowledge centralisation and tool production to impact monitoring and communication.

The project's effort includes the development of a Common guideline for monitoring soil's properties and crop's performance led by the Spanish National Research Council (CSIC) and the University of Wageningen (WUR). This guideline will serve as a crucial tool for decision-makers, optimizing the utilization of processed food waste, reducing environmental risks, fostering sustainable agricultural practices, and assessing the effects of soil improvers on soil health indicators.

Waste4Soil represents a significant stride towards a more sustainable and circular approach to managing food processing residues, improving soil health, enhancing crop performance, and fortifying food systems' resilience.

<sup>3</sup> Agrobiotechnology Laboratory, Department of Chemistry & Biotechnology Center, Universidad Técnica Federico Santa María., Valparaíso, CHILE

Worldwide and nationally, there is a significant issue of contamination from textile waste lacking any reutilization or degradation plan. Approximately 100 million tons of textile solid waste are generated annually. This trend is a consequence of 'fast fashion,' which aims to sell 'disposable' clothing at a low cost, produced under a highly polluting linear lifecycle, with natural resources being used intensively and inefficiently. In Chile, less than 1% of the material used in clothing production is recycled, with 85% of textiles ending up in landfills or being incinerated. This study aims to reduce the vast amount of waste generated by this industry by employing bacterial strains with cellulolytic activity isolated from the Chilean desert soil. The capability of 35 strains to degrade textile material in liquid medium over 40 days was assessed, and 4 strains were selected for their ability to reduce the textile weight by 50%. In vitro cellulose degradation assays revealed that these 4 strains degrade over 50% of the cellulose present in textiles. This technology is environmentally friendly, promoting the sustainability of territories, minimizing environmental impact, and contributing to the circular economy through the reuse of degradation by-products. It is a harmless technology that addresses health concerns in more contaminated areas.

### URBAN LIVING LABS FOR SOIL CONSERVATION - ENHANCING CITIZEN'S FOOD SECURITY

A. TERNELL<sup>2</sup>, T. RÅBERG<sup>1</sup>

<sup>1</sup> Research Institutes of Sweden, Göteborg, SWEDEN

<sup>2</sup> University of Pécs, Inst. of Earth Sciences, HUNGARY

Soil mechanical degradation and pollution in urban and peri urban areas often represent an environmental barrier to the development of urban agriculture in available free spaces. Therefore, soil remediation is a first step to soil conservation, which can be interpreted as a set of farming methods and good practices that maintain soil health and keep the land from physical and chemical degradation, loss of biodiversity and erosion. The structure of the soil, its organic matter content, its water holding capacity and biota are key factors to cultivate good quality crops. Turning the often heavily polluted brown fields into green areas of agricultural production, urban gardens or peri-urban farms and agroforestry is a process, which requires both a wide range of public resources, involvement of private enterprises and community participation. Urban Living Labs are means for channelling of the participatory synergies of local governments, stakeholders, and civil society by establishing criteria, preferences, and innovative solutions for the development of experiences and the implementation of good practices in local and sustainable food production and their active involvement in spatial planning. The implementation of Urban Living Labs (with a strong citizen intervention) allows to draw conclusions regarding the capacity building potential of participatory methods and social innovation to solve citizen problems in different contexts (stakeholders, citizen profiles, social, cultural, economic, demographic context). This becomes even more relevant considering that the socio-economic and environmental problems to be addressed in all locations will be the same: what is the best way to extend or further extend the experiences of healthy and sustainable food production in urban, peri urban and semirural areas. Thus, conditions for urban agriculture can be assessed through data provided by the well-monitored activities of Urban Living Labs in the scope of spatial and functional benefits (urban gardens as a part of sustainable multifunctional urban space), cultural and economic benefits (urban gardens as social nodes and opportunity for business start-ups), and health benefits (urban gardens as the source of organic food and the place for physical activity). The existing urban gardens in the city will reveal potential benefits of conversion of other areas to new urban gardens taking into consideration the impact on microclimate, possible air and water pollution reduction, soil recultivation, water retention and inundation, ground water levels, floods risk reduction, and increasing biodiversity.

<sup>6</sup> USDA-ARS, Ames, USA

Remote sensing tools along with Global Navigation Satellite System cattle collars and digital soil maps may help elucidate spatiotemporal relationships among soils, terrain, forages, and animals. However, standard computational procedures preclude systems-level evaluations across this continuum due to data inoperability and processing limitations. Deep learning, a subset of neural network analysis, may elucidate efficiency of livestock production and linkages within the livestock-grazing environment. Consequently, we applied deep learning to 1) develop predictive models for yield and forage nutrition based on vegetation indices; and 2) at pixel-levels, identify how grazing is linked to soil properties, forage growth and nutrition, and terrain attributes in silvopasture and pasture-only systems. Remotely sensed data rapidly and non-destructively estimated herbage mass and nutritive value for enhanced net and primary productivity management in livestock and grazing systems. Cattle grazed big bluestem (*Andropogon gerardii* Vitman) with 182% greater frequency than orchardgrass (*Dactylis glomerata* L.) in the pasture-only system. Real-time estimates of vegetative bands may assist in predicting grazing pressure over time and space for more efficient management of pasture resources. Cattle grazing followed distinct soil-landscape patterns, namely reduced cattle grazing preference occurred in areas of water accumulation, which highlights linkages among terrain features—soil-water movement—soil properties—forage nutrition—and animal grazing response spatially and temporally. Results from this study could be scaled to greater extents to improve grazing management among the largest land-use category in the U.S., grasslands, which would allow for sustainable intensification of forage-based livestock production to meet growing demands for environmentally responsible protein.

#### A ROOT–SOIL DIELECTRIC APPROACH FOR NON-DESTRUCTIVE WHEAT PHENOTYPING IN ORGANIC FARMING

I. CSERESNYÉS<sup>1</sup>, P. MIKÓ<sup>2</sup>, E. TÓTH<sup>1</sup>, Á. HOREL<sup>1</sup>, T. ZSIGMOND<sup>1</sup>, T. TAKÁCS<sup>1</sup>, K. POKOVALI<sup>1</sup>

<sup>1</sup> Institute for Soil Sciences, HUN-REN Centre for Agricultural Research, Budapest, HUNGARY

<sup>2</sup> Agricultural Institute, HUN-REN Centre for Agricultural Research, Martonvásár, HUNGARY

Root system is an obvious target to develop crops with improved soil resource acquisition in low-input systems. Measurement of root–soil dielectric response is a promising approach for high-throughput root evaluation without plant injury and soil disturbance. As root electrical capacitance (CR\*) depends on the stem properties, the efficiency of measuring CR\* at flowering for whole-plant phenotyping was assessed in a two-year study in five winter wheat cultivars grown under organic conditions. Linear regression models were built to correlate CR\* with plant-size parameters and flag-leaf traits (extension and SPAD chlorophyll content) at flowering, and with yield components at maturity. The plot-mean CR\* was correlated with the ceptometer-based plot leaf area index (LAI), the chlorophyll quantity (LAI×SPAD) and the grain yield across the years. At plant scale, CR\* was found to show the strongest positive regression with total chlorophyll in the flag leaf (flag leaf area × SPAD; R<sup>2</sup>: 0.65–0.74) and with grain mass (R<sup>2</sup>: 0.55–0.70) for each cultivar and year. Likewise, at plot scale, the regression was the strongest between CR\* and the LAI×SPAD value (R<sup>2</sup>: 0.86–0.99) for the cultivars. Consequently, CR\* indicated the total plant nutrient and photosynthate supply at flowering, which depended on root uptake capacity, and strongly influenced the final yield. Our results suggested that the polarization of the active root membrane surfaces was the main contributor to CR\*, and that the measurement could be suitable for evaluating root size and functional intensity. In conclusion, the capacitance method can be applied for non-destructive whole-plant phenotyping, with potential to estimate root and shoot traits linked to the nutrient supply, and to predict grain yield. CR\* can be incorporated into allometric models of cereal development, contributing to optimal crop management and genetic improvement. The dielectric measurement can be integrated into other proximal sensing techniques, including root visualizations and detecting vegetation indices i.e. LAI, NDVI or PRI.

The project was funded by the NKFIH, Hungary (FK-137617).

#### SOIL ELECTRICAL CONDUCTIVITY IN SATURATED PASTE EXTRACTS AND IN DIFFERENT SOIL:WATER SUSPENSIONS. MEDITERRANEAN CENTRAL CHILE

M. CASANOVA, Y. TAPIA, J. BAUTISTA, O. SALAZAR, M. PFEIFFER

Depto. de Ingeniería y Suelos, Facultad de Ciencias Agronómicas. Universidad de Chile, SANTIAGO, CHILE

As an alternative to measuring the electrical conductivity of the saturated paste extract ( $EC_e$ ), the electrical conductivity in water suspensions ( $EC1:X$ ) was measured, with three different soil:water ratios and 5 replications in clay, clay loam to loam and sandy loam to sandy clay loam soils (Mollisols, Vertisols and Entisol) at Mediterranean central Chile, characterized by a Csb2Sa climate (Köppen). The relationships between the  $EC_e$  and the  $EC1:X$  were evaluated on mass/volume and volume/volume basis at laboratory ( $EC1:1$  m/v,  $EC1:2.5$  m/v,  $EC1:5$  m/v,  $EC1:1$  v/v,  $EC1:2.5$  v/v,  $EC1:5$  v/v), as well as volume/volume in the field or in situ ( $EC1:1$  v/v is,  $EC1:2.5$  v/v is,  $EC1:5$  v/v is). The relationship between the different measured EC and some soil properties (texture, pH, water content at saturation, at 33, and at 1500 kPa) was also evaluated. Elevated and significant linear correlation between  $EC_e$  and  $EC1:X$  were observed ( $r$ : 0,81 to 0.92), besides to identify saline soils in the study area ( $EC_e > 4$  dS/m), the following values should be reached (dS/m):

$EC1:1$ m/v	> 2.35	or	$EC1:2.5$ m/v	> 1.20	or	$EC1:5$ m/v	> 0.72
$EC1:1$ v/v	> 2.27	or	$EC1:2.5$ v/v	> 1.28	or	$EC1:5$ v/v	> 0.74
$EC1:1$ v/v is	> 2.48	or	$EC1:2.5$ v/v is	> 1.33	or	$EC1:5$ v/v is	> 0.74

Finally, of the variables selected by the stepwise regression analysis, the silt content is the most common in all the models, followed by the pH of the soil:water suspension (1:1m/v; 1:2,5m/v and 1:2,5v/v; 1:5v/v).

#### SENSITIVITY ASSESSMENT OF ARTIFICIAL NEURAL NETWORK FOR SOIL ORGANIC CARBON PREDICTION USING HYPERSPECTRAL RADIOMETRIC DATA

P. SHARMA, A. PANCHADI, P.K. SRIVASTAVA

BANARAS HINDU UNIVERSITY, Varanasi, INDIA

The aim of this study was to assess the sensitivity of hyperspectral radiometric data in the visible, near-infrared (NIR) and shortwave-infrared (SWIR) region (350–2500 nm) to soil organic carbon (SOC) content. Hyperspectral radiometric data measures reflectance of light across a range of wavelengths and has been proposed as a potential tool for predicting SOC content in soil. The study employed seven spectral indices such as Hue Index (HI), Brightness Index (BI), Colouration Index (CI), Saturation Index (SI), Soil Composition Index (SCI), Soil Organic Carbon Index (SOI), and Optimised Soil Adjusted Vegetation Index (OSAVI) based on laboratory spectral measurements of soil reflectance using an ASD FieldSpec Pro spectroradiometer, combined with laboratory chemical analyses of soil samples to determine SOC concentrations. Following this an Artificial Neural Network (ANN) model was developed to predict SOC content using spectral indices data tested for optimal model performance. Results showed that hyperspectral radiometric data was highly sensitive to SOC content, with root mean square error (RMSE) of 0.08 during calibration, 0.07 during validation and mean absolute error (MAE) of 0.06 during calibration and validation indicating that this technology could be an effective tool for accurately predicting SOC content in soil. Sensitivity assessment of ANN was carried out to find the most sensitive variables using Lek's profile method. Results of sensitivity analysis shown SOI and HI as most sensitive variables in prediction of SOC. These results hold potential for mapping SOC content at a large scale. In conclusion, the study highlights the potential of hyperspectral radiometric data for accurately predicting SOC content in soil. Thus, this technology in the visible, NIR and SWIR region has shown promising results, making it a valuable tool for precision agriculture and environmental monitoring.

#### A FIRST ITALIAN SOIL SPECTRAL LIBRARY WITH A LOW-COST NIR SPECTROMETER FOR SOIL ORGANIC CARBON PREDICTION

S. PRIORI, M. ZANINI, L. PACE

University of Tuscia, Department of Agriculture and Forest Sciences, Viterbo, ITALY

Over the past two decades, visible and near-infrared (VIS-NIR) diffuse reflectance spectroscopy has gained popularity for soil analysis, because of its rapid and inexpensive acquisition methods. Recently, technological developments have allowed the fabrication of small NIR spectrometers at much lower cost than the traditional ones. Such devices are based on “micro-electromechanical systems” (MEMS), and are usually composed of an interferometer, consisting of an oscillating mirror and beam splitters, as well as an InGAs photodetector. This work aims to present a first Italian soil spectral library created using a low-cost and handheld NIR-MEMS spectrometer (Si-Ware Neospectra Scanner, bandwidth 1350-2500 nm). The library contains a total of 664 NIR spectra coming from several regions, associated with conventional laboratory analysis. 283 samples belong to forest soils (252 from A horizon, 31 from subsoil horizons), whereas 381 samples belong to agricultural soils (297 from A horizon, 84 from subsoil horizons). Some of the scanned soil samples derived from the Italian soil archives of CREA-AA Research Centre in Florence, whereas others come from different soil survey campaigns or scientific collaborations of this research group.

Partial Least Square (PLSR) and Support Vector Machine (SVM) regressions were tested to predict soil organic carbon (SOC), after a pseudo-normalization of the SOC data by log-transformation. 10 k-fold cross validation was carried out to calculate the prediction errors. PLSR provides slightly better results than SVM, in terms of R<sup>2</sup> (0.75) and root mean square error of prediction. The accuracy increases when the PLSR model is calibrated within a specific subset, such as “topsoil in agriculture” and “topsoil in forest”. SOC prediction of subsoil horizons provides slightly lower accuracy.

#### THE RELATIONSHIP BETWEEN SOIL HYDRAULIC PROPERTIES AND PARAMETERS OF PLANT GROWTH IN A FIELD WITH SPATIALLY HETEROGENEOUS SOIL PROPERTIES

U. PECAN<sup>1</sup>, K. ELER<sup>1</sup>, D. KASTELEC<sup>1</sup>, M. NOC<sup>1</sup>, M. GLAVAN<sup>1</sup>, M. PINTAR<sup>1</sup>, M. ZAJC<sup>2</sup>

<sup>1</sup> University of Ljubljana, Biotechnical Faculty, Ljubljana, SLOVENIA

<sup>2</sup> Geological Survey of Slovenia, Ljubljana, SLOVENIA

The water available to plants depends on soil properties, which are spatially variable even at the field parcel scale. The spatial variability of plant available water is caused by the variability of soil texture, depth, the presence of rock fragments, organic matter content and dry soil bulk density, among other factors. The variability of soil properties is also reflected in plant growth. The leaf area index (LAI) is a biophysical plant parameter that reflects the environmental factors in the field and is an indicator of plant growth. Remote sensing is proving valuable for monitoring agricultural systems as it enables the calculation of plant vegetation indices by using multiple spectral bands. The normalized difference vegetation index (NDVI) is commonly used for the detection of plant activity. The aim of this study was to investigate the relationship between the maize growth measured as in-situ LAI and remotely sensed vegetation index (NDVI), and soil parameters such as plant available water, current soil water content and dry soil bulk density. Multi-layer measurements were conducted in a field with spatially variable soil properties in Šempas, located in the western part of Slovenia. Forty georeferenced measurement points were defined on the field, from each of which we obtained undisturbed soil samples to determine gravimetric soil water content, water content at pF 2.0 and dry soil bulk density. Disturbed soil samples were used to determine the water content at pF 4.2. LAI measurements were taken using a ceptometer, and a drone surveyed the entire field from which the point NDVIs were calculated.

The research was funded by the Slovenian Research and Innovation Agency (ARIS) project no. J1-4412.

#### LEAF AREA MEASUREMENTS IN EVALUATING TILLAGE METHODS IN A LONG-TERM SOIL CULTIVATION EXPERIMENT AT HUNGARY, 2016-2022

K. POKOVAI <sup>1</sup>, E. TOTH <sup>1</sup>, M. DENCSE <sup>1</sup>, M. BIRKÁS <sup>2</sup>, I. CSERESNYÉS <sup>1</sup>, J. MÉSZÁROS <sup>1</sup>, Z. BAKACSI <sup>1</sup>

<sup>1</sup> HUN-REN Centre for Agricultural Research, Institute for Soil Sciences - Department of Soil Physics and Water Management, Martonvásár, HUNGARY

<sup>2</sup> Hungarian University of Agriculture and Life Sciences, Institute of Crop Production Sciences - Department of Agronomy, Gödöllő, HUNGARY

An essential goal of crop management is to increase crop productivity and to enhance soil health within constraints imposed by economic considerations. How the soil is cultivated is crucial to achieving this objective. Regarding crop productivity, leaf area and yield are important plant parameters.

Ceptometry (Accupar LP-80), a well-established non-destructive optical assessment method, offers an in situ measurement of the canopy size (Leaf Area Index LAI).

The objective of this study was to determine the influence of tillage on LAI and yield of crops under continental climate conditions located in Józsefmajor, Northeastern Hungary. The long-term soil cultivation experiment were conducted on chernic calcic Chernozem developed on loamy clay, under no-tillage (NT), mouldboard plough (MP) and shallow cultivation (SC) tillage systems. The crop sequence in the years (2016 – 2022) was, in order maize, winter oat, soybean, winter wheat, winter oat, sunflower and barley. LAI was measured at flowering, when the foliage reached its maximum size.

Results indicated that LAI is the lowest at NT in all years but 2022 and the highest in MP in 2016, 2017, 2018 and 2020, and in SC in 2019, 2020; although treatments are not significant in 2018 and 2020, and MP-SC is not significant in 2021. Yield is the lowest at NT in most years but 2020, 2022, although 2020 is not significant, and the highest in MP in 2017, in SC in 2016, 2018, 2019, 2020, 2022. SC-MP differences are not significant in all years.

Overall, the tillage method had a significant effect on yield and mostly on ceptometer-based LAI, too. NT treatment was associated with lower LAI and yield loss compared to MP and SC treatments. The highest LAI values were generally measured in the MP treatments, while the highest yield values were generally obtained in the SC treatments.

The research was funded by the Sustainable Development and Technologies National Programme of the Hungarian Academy of Sciences (FFT NP FTA).

#### IMPACT OF SOIL CONDITIONERS ON WATER SENSORS

M. MARIN, F. ELSAKLOUL, G.J. NORTON, P.D. HALLETT

University of Aberdeen - School of Biological Sciences, Aberdeen, UNITED KINGDOM

In precision agriculture sensors can monitor field conditions to optimise resource input to reduce costs and improve sustainability. The global agriculture sensors market is expected to be worth 16.83 billion USD by 2030. Water content sensors are fundamental to monitor soil moisture, playing a key role in irrigation scheduling for precision agriculture. Climate-smart agriculture has also focused on improving soil moisture retention by adopting water-holding enhancement strategies such as the use of soil conditioners. However, despite “sensor deployment” and “soil conditioners” both intended to improve water use efficiency, data are lacking on the responses of soil water sensors to soil conditioners for enhanced water holding capacity. The present study assessed the effect of different soil conditioners on the performance of a range of soil water sensors. We evaluated soil moisture sensor readings taken in a sandy soil, with added biochar (2.5% w/w), compost (5% w/w), hydrogel (0.6% w/w) and water treatment residue (5% w/w). The soils were saturated and then subjected to wetting and drying cycles. Measurements were taken continuously using multiple commercial sensors: ML3 ThetaProbe and SM150T soil moisture sensors (Delta-T Devices Ltd, Cambridge, UK) as well as EC-5 soil moisture sensors (Meter Environment, Pullman, WA, United States). We observed a tendency by ML3 and SM150T sensors to underestimate water content at low water content values (actual VWC < 30%), while overestimating water content at high water content values (actual VWC > 40%), using the intrinsic manufacturer calibration. In contrast, EC-5 sensors underestimated water content at both low- and high-water contents. Using a soil specific calibration, the presence of soil conditioners exacerbated the tendency to both underestimate and overestimate the actual water content. Our results showed the need for “conditioner-specific calibrations” when soil is amended with different conditioners. The interactions between soil conditioners and water content readings taken by soil moisture sensors will be discussed in detail, along with their repeatability and accuracy.

<sup>3</sup> National Laboratory for Water Science and Water Security, HUN-REN Centre for Agricultural Research, Ins. for Soil Sciences, Budapest, HUNGARY

Spectral tools and measurements are established techniques in Digital Soil Mapping for obtaining information on quantitative soil parameters to minimize the number of actual soil samples required from the field. Such tools can be point measurement sensors like spectroradiometers and optical imaging spectrometers (multi- or hyperspectral cameras).

In this study, we tested a combined method in a small vineyard located in Upland Balaton, Hungary. The study area is appr. 10 ha. Three different inter-row soil management were investigated (tillage, cover crops and perennial grass). The soil in the area is generally Cambisol or Luvisol, developed from loess.

Three different datasets were collected: i) field spectra measured with an ASD FieldSpec Pro spectroradiometer and laboratory analysis of 22 soil samples (referred as 'real' samples) from evenly distributed locations across the sample site, ii) similar spectra at a further 22 'virtual' points generated by the Conditioned Latin Hypercube Sampling method using topomorphometric (Digital Elevation Model and its derivatives) and multispectral raster layers as input, both generated from UAV surveys, and iii) spectral and topographic raster information from the aforementioned aerial measurements.

During our processing workflow, a two-step method was implemented. Firstly, a 'ranger' random forest based model was built to predict selected soil parameter values from spectral data of both the 'real' samples (as training data) and also for the 'virtual' points. As a second step, these predicted soil parameter values of the virtual points were used together with the laboratory measured data of the 'real' soil samples as training data to model and map the whole study site based on the spatially exhaustive aerial survey layers.

The accuracy and the uncertainty assessment of both steps were examined to evaluate the proposed method.

#### DIGITAL MAPPING AND MONITORING OF INDUSTRIALIZED URBAN SOILS

Z. FEHÉR, E. BÓDI, J. TAMÁS, A. NAGY, N. SZOLLOSI, P.T. NAGY

University of Debrecen, Debrecen, HUNGARY

The city of Debrecen, a rapidly industrializing lowland area poor in surface waters, where the different soil characteristics of 3 larger geographical regions have been fundamentally transformed by modern urbanization. In addition to German rolling bearing production and the automotive industry, battery production from Asia is also expanding rapidly. This obviously means the withdrawal of more than a thousand hectares of land, the paving of significant areas and the emergence of potential sources of emissions. The monitoring network implemented in the city's TÓCÓ catchment, which is the most exposed to environmental risks, aimed to meet these challenges. A geodatabase built from photogrammetry, LIDAR and satellite data was built into the urban soil model. ESRI Survey123 mobilGIS and GPS RTK survey was carried out at nearly 500 points in 5 regions with 0-0.2m surface sampling and 360 images for later identification of plant phenology and soil condition. After drying and sifting the samples, heavy metals, humus content, clay fraction analysed by NITON XRF, Agiland FTIR sensors and spectral VIS-NIR reference curves were measured and hydraulic conductivity also calculated. Based on geostatistical studies, the size of the large database was reduced to critical hot spots, which further evaluate the sediments movements and pollution risks of flash floods in urban river basin models within the framework of the monitoring. The important fact about the studies is that not only the potential risks s have to be taken into account, but also the significant watercourse revitalization completed last year, when significant ecological water supply and river bed construction with new hydraulic gauges was also carried out on TÓCÓ. These processes assume that we perform sensing that provides quasi-real-time data collection and evaluation. The research work funded by RRF-2.3.1-21-2022-0008 project

#### COMPARISON OF ARTIFICIAL NEURAL NETWORK (ANN) AND PARTIAL LEAST-SQUARES REGRESSION (PLSR) FOR ESTIMATING SOIL ORGANIC CARBON BY VIS-NIR SPECTROSCOPY: A CASE STUDY IN A KIWI ORCHARD IN SOUTHERN ITALY

M. CONFORTI<sup>1</sup>, M. MERCURI<sup>1</sup>, G. BUTTAFUOCO<sup>2</sup>

<sup>1</sup> National Research Council of Italy, Research Institute for Geo-Hydrological Protection (CNR-IRPI), Rende, ITALY

<sup>2</sup> National Research Council of Italy, Institute for Agricultural and Forest Systems in the Mediterranean (CNR-ISAFOM), Rende, ITALY

Soil organic carbon (SOC) affects soil properties and processes as well as is an important sink and source of plant and microbial nutrients. Visible and near-infrared reflectance spectroscopy (Vis-NIR, 350–2500 nm) has become an important method for measuring and monitoring SOC. However, analysis of soil diffuse reflectance spectra data requires complex mathematical treatments to extract useful information and relate traditional measures of SOC concentrations to spectral data. Defining the most suitable methods for relating SOC measures to diffuse reflectance spectra is an active field of research which requires further study. The study was developed within E-Crops Project – Technology for Sustainable Digital Agriculture (National Operational Programme on R&I 2014–2020, Italy), and aimed to compare ANN and PLSR for estimating SOC by Vis-NIR spectroscopy. Topsoil (0–0.20 m) samples were collected at 126 locations within a kiwi orchard in Basilicata region (southern Italy) and analyzed for SOC concentration using a Shimadzu TOC-L analyzer. Vis-NIR reflectance spectra were measured in laboratory using an ASD FieldSpec IV 350–2500 nm spectroradiometer. Accuracy and robustness of ANN and PLSR models were evaluated by a ten-fold cross-validation method based on R<sup>2</sup>, root mean square error (RMSE), and relative percent deviation (RPD). The dataset was randomly divided into ten equal sized groups (folds). One of the groups (10% of the dataset) was retained as validation data for testing the models, whereas the remaining groups (9 folds or about 90% of the selected data set) were used as training data. The process was repeated ten times, and each fold was used only once as validation data. The average of ten repeated processes was calculated to generate the SOC prediction models. The results showed that the prediction models obtained by ANN (mean R<sup>2</sup>= 0.94; mean RPD=4.07) performed better than those by PLSR (mean R<sup>2</sup>= 0.79; mean RPD=2.16). However, both PLSR model and ANN model were quite stable when calibration and validation sets were changed through the ten-fold cross-validation.

#### IDENTIFICATION OF PRODUCTIVITY ZONES BASED ON LANDSCAPE FACTORS AND SOIL PROXIMAL SENSING DATA IN ORGANIC FARMING

N. THAKUR<sup>1</sup>, K. GOLICTZ<sup>2</sup>, S. BELLINGRATH-KIMURA<sup>1</sup>, A. GATTINGER<sup>2</sup>

<sup>1</sup> Leibniz Institute of Agricultural Landscape Research, Muencheberg, GERMANY

<sup>2</sup> Justus-Liebig University, Giessen, Giessen, GERMANY

In the past few years uniform management of fields in agriculture has been gradually replaced by environmentally based management, which involves exploiting the multifunctionalities of landscapes. In cases of organic agriculture, which is a low input system, there is always a risk of lower yields. To mitigate the tradeoff between environmental benefits and lower yields, landscape features can be taken advantage of to optimize productivity in organic agriculture. For this, geodata, along with soil data measured with proximal sensing equipment was used for an organic mixed farming experimental site in Hesse, Germany. The calculation of the metrics that affect crop growth was done with satellite data in two scales: Sentinel 2 images in 10 m resolution and PLANET Scope Images in 3 m resolution for the period of 2020-2023 in the vegetation periods. The vegetation indices for the crop was calculated with the help of GIS tools and python. The soil texture was inferred with the apparent soil electrical resistivity values and the natural gamma emissions measured with the novel Geophilus proximal sensing equipment. Soil heterogeneity was then calculated based on the texture data and ground truth values of soil moisture, infiltration rates and soil organic matter content with the help of a Multi Linear Regression model. The two datasets of soil heterogeneity data and crop data were compared to identify indicators of crop growth. Then finally elevation was taken into account to identify risk areas vulnerable to erosion. Thus, with a data-driven approach, the field site was analyzed to identify zones which are relatively more productive in terms of soil quality and crop growth, as well as zones where ecosystem services like planting hedgerows are necessary to mitigate soil erosion. These zones were visualized with GIS tools resulting in maps that can be used by farmers to optimize yields by changing or modifying the management practices with respect to the yield potential of soils.

Iron oxides, critical indicators of soil development in the B horizon, present a challenge for traditional analysis methods such as free iron oxide (Fed), total iron (Fet), and freeness of iron (Fed/Fet\*100%), which are time-consuming and increasingly impractical in the context of modern precision agriculture. This study adopts an innovative approach by using smartphones as proximal sensors to capture soil color parameters, thereby offering a rapid and accessible method for estimating soil iron oxide content. By harnessing smartphone technology to assess key soil color determinants, especially iron oxides, this study aims to surmount the limitations of traditional analysis techniques and pave the way for advancing smart agricultural practices. Five smartphones with high-resolution cameras and accurate color performance were chosen to image 150 soil samples in various lighting conditions, alongside hyperspectral scans for detailed spectral data beyond the visible spectrum. Utilizing the obtained soil data, support vector machine (SVM) and partial least squares regression (PLSR) models were developed to predict iron oxide content. For Fet, the models demonstrated moderate to strong predictive capabilities, with R<sup>2</sup> values ranging from 0.57 to 0.66. However, the model's prediction errors, indicated by RMSE values ranging from 12.57 to 15.34 g/kg for Fet, suggest there is room for improvement in prediction accuracy. Despite this, the RPD values, ranging from 1.50 to 1.73, underscore the models' acceptable to good ability to predict soil iron oxide levels. These statistical indicators collectively affirm the potential of using smartphones as reliable tools for soil analysis in precision agriculture, albeit with some limitations in prediction precision that could be addressed through model optimization. Additionally, a comparative analysis of spectral response curves across smartphones revealed more accurate models for iron oxide estimation, with devices showing stronger spectral responses and pronounced peaks in the R band. This study demonstrates that smartphones, alongside advanced algorithms, offer a viable and efficient solution for predicting soil iron oxide content, significantly enhancing precision agriculture practices.

Cosmic Rays Neutron Sensing (CRNS) became an increasingly important technology in Hydrology thanks to its capability of measuring soil water content in a wide area and in depth. It's based on the detection of neutrons, particles naturally flowing from space and strongly interacting with water molecules. A single CRNS probe can provide a value of soil moisture representative of a volume up to a dozen hectares and up to 50 cm deep, in real-time, positioning itself in an horizontal spatial scale in between point measurements and satellites.

The actual availability of water resources is regulated by soil characteristics, in particular its texture and structure. It is often difficult to establish the expected dynamical boundaries of the water reservoir because of the natural complexity of the soil, which can have a large variability also in small areas.

A CRNS probe offers the possibility to provide a non-invasive year-round monitoring of soil moisture dynamics of a field, while spontaneously averaging over the complexity of soil. At the same time, point-scale probes together with a soil mapping approach allow to interpret the soil-landscape model of each site, which strongly affects soil moisture dynamics and distribution, enabling to understand and validate CNRS averaged data.

Moreover, CRNS probe spatial scale is comparable with the remote sensing pixel, allowing to interpolate data between two different satellite passes, extending the spatial significance of the collected data.

We here report observations from a set of sites in Northern Italy where Finapp CRNS probes have been installed, and discuss how the integration and synergy of Finapp CRNS with the other techniques and site-specific pedological knowledge can provide a more complete and reliable understanding of soil moisture dynamics from local to regional scale.

Maritime Antarctica (M.A.) contains the most extensive and diverse lithological exposure compared to the entire continent. Although geophysical surveys can detect and provide valuable information to understand Antarctic lithologies and their history, such surveys are scarce on this continent and, in practice, almost non-existent. The main objective was to create ternary gamma-ray and K maps using machine learning algorithms, terrain attributes, and a nested-leave-one-out cross-validation method. Additionally, we investigated the relationship between the distribution of natural radioactivity and K to gain insights into pedogeomorphological and periglacial processes and dynamics. For that, we used proximal gamma-spectrometric and data in different lithological substrates associated to terrain attributes. The geophysical variables were collected in the field from various lithological substrates, by use field portable equipment. The geophysical variables were collected in the field from various lithological substrates K using portable equipment. These variables, combined with relief data and lithology, served as input data for modeling to predict and spatially map the content of radionuclides and K by random forest algorithm (RF). The RF algorithm successfully generated detailed maps of gamma-spectrometric and K variables. The highest thorium levels were observed in elevated, flat, and west beach areas, where detrital materials from periglacial erosion came through fluvioglacial channels. Lithology and pedogeomorphological processes-controlled thorium contents. Lithology and pedogeochemical processes governed potassium levels. Pyritized-andesite areas had the highest levels due to sulfurization and associated pyrrhotite, promoting iron release. The complex interplay of various periglacial processes in the area, along with the morphometric features of the landscape, leads to the redistribution, mixing, and homogenization of surface materials, contributing to the inaccuracies in the predicted-spatialized geophysical variables.

Soil organic carbon (SOC) is a critical factor influencing global carbon cycling. Accurate estimates of its spatial distribution are essential for addressing global climate change. Digital soil mapping has demonstrated significant potential in providing precise and high-resolution spatial information about SOC across various scales. We conducted an evaluation of two soil mapping approaches for SOCD estimates in France: the direct approach (calculate-then-model) and the indirect approach (model-then-calculate). Our study utilized 916 topsoil samples (0 ~ 20 cm) from the LUCAS Soil 2018 dataset and 24 environmental covariates. We employed a random forest model and forward recursive feature selection to build spatial predictive models of SOCD using both the direct and indirect approaches. The results revealed that, with the random forest model and full covariates, both approaches demonstrated moderate performance ( $R^2 = 0.28 - 0.32$ ). Through the use of forward recursive feature selection, the number of predictors was reduced from 24 to 9, leading to enhanced model performance for the direct approach ( $R^2$  of 0.35), while no improvement was observed for the indirect approach ( $R^2$  of 0.28). The mean SOCD of French topsoil was estimated at 5.29 and 6.14 kg m<sup>-2</sup> using the direct and indirect approaches, respectively, resulting in SOC stocks of 2.8 and 3.3 Pg, respectively. Notably, the indirect approach exhibited better performance in estimating high SOCD. These findings serve as a valuable reference for SOCD mapping.

### GLOBAL-LOCAL: A NEW APPROACH FOR LOCAL PREDICTIONS OF SOIL ORGANIC CARBON CONTENT USING LARGE SOIL SPECTRAL LIBRARIES

M. ST. LUCE <sup>1</sup>, N. ZIADI <sup>2</sup>, R. VISCARRA ROSSEL <sup>3</sup>

<sup>1</sup> Agriculture and Agri-Food Canada, Swift Current, CANADA

<sup>2</sup> Agriculture and Agri-Food Canada, Quebec City, CANADA

<sup>3</sup> Curtin University, Perth, AUSTRALIA

There is much interest in the use of large visible near infrared (vis-NIR) soil spectral libraries for rapid soil analysis. However, their use often provides biased predictions at local scales. We developed a new approach, GLOBAL-LOCAL, to develop spectroscopic models that can fit locally. This requires the selection of the most common spectral neighbours of a small representative set (Lab) from the target site using a combination of principal component analysis (PCA) and k-nearest neighbours, followed by selection of the calibration with the lowest root mean square error (RMSE) in predicting the Lab. The Lab samples are then added to the best calibration to derive the GLOBAL-LOCAL. This approach was evaluated by predicting the soil organic carbon (SOC) content in two different target sites; Lévis, QC, Canada (N = 111) and Maaninka, Finland (N = 101). Partial least squares regression (PLSR) was used for model development and validation. We used a combination of the spectral libraries developed by the World Agroforestry Center and International Soil Reference Information Centre (N = 3875), and by the Quebec Research and Development Centre of Agriculture and Agri-Food Canada (N = 1051). Our results showed that prediction accuracy of the GLOBAL-LOCAL for Lévis and Maaninka (RMSE = 1.41 and 3.08 g kg<sup>-1</sup>, RPIQ = 5.9 and 4.1, respectively) were better than using the global calibration (RMSE = 20.3 and 23.6 g kg<sup>-1</sup>, RPIQ = 0.41 and 0.53, respectively). The GLOBAL-LOCAL was also better or similar to site-specific calibrations (RMSE = 2.38 and 4.68 g kg<sup>-1</sup>, RPIQ = 3.5 and 2.7, respectively). Moreover, GLOBAL-LOCAL outperformed three other approaches, RS-LOCAL, the spectrum-based learner and LOCAL. The approach uses the information in the large spectral library so that it can substantially reduce analytical cost and greatly improve predictions on local scales.

<sup>2</sup> INRAE, Info&Soils, ORLÉANS, FRANCE

<sup>3</sup> Austrian Research Centre for Forests, VIENNA, AUSTRIA

Agricultural soils are significant reservoirs of organic carbon, playing a crucial role in maintaining soil fertility, water retention, and overall ecosystem health. The impact of climate change on these soils is crucial, and understanding the current state and future projections is key for sustainable land management practices. The aim here is to investigate the potential impacts of climate change on SOC stocks, considering changes in temperature and precipitation in 2050 and 2100 in Polish agricultural soils. This study quantifies present SOC stocks based on over 40,000 soil samples and assesses the impact of the projected climate change on long-term SOC stock changes in Poland, using the digital soil mapping approach. We investigated the projected changes for 2050 and 2100 under two different Representative Concentration Pathways (RCP 4.5: sustainable scenario and RCP 8.5: high-emission scenario with significant climate impacts). Initial analyses suggest complex spatial changes indicating a significant influence of climatic conditions on SOC stock dynamics and SOC stability. Our primary results allow to identify three main regions in Poland where the dynamic of SOC stock can be the highest. The largest losses of SOC may occur in the areas surrounding Wrocław, and in the Upper Vistula Valley, the southern part of Poland. This may be caused by the increase in temperatures and decrease in precipitation in those areas. On the other hand, we observe also the increase in SOC stock in the northern part of Poland within the areas of relatively dense occurrence of organic soils. This change is linked to the increase in both temperatures and precipitation in this area. In that context, forecasts may significantly contribute to the further strategies of creation of National Soil Monitoring according to the Proposal for a Directive on Soil Monitoring and Resilience by indicating the high-priority areas or the analysis of the possibilities to reach the EU Green Deal targets.

<sup>2</sup> Research Institute for Soil and water Conservation (VUMOP), Prague, CZECH REPUBLIC

<sup>3</sup> Department of Geography and Geology, Faculty of Science, Charles University, Prague, CZECH REPUBLIC

We applied the Digital Soil Mapping (DSM) approach to map soil organic carbon (SOC) content across Krasna Hora Nad Vltavou, situated in the Pribram District, Central Bohemian Region, Czech Republic. We focused on two soil layers: 0-10 cm (SOC 10) and 0-30 cm (SOC 30), employing various machine learning models. The study area covers approximately 500 km<sup>2</sup>, characterized by elevations ranging from 268 to 574 m a.s.l., with geomorphologic classification as a Bohemian highland featuring gently undulating mountains. Predominant land cover primarily consists of arable lands with some forested areas. Utilizing data from 105 georeferenced soil profiles sampled by horizons, we analysed soil samples in the laboratory for organic carbon and total nitrogen using dry combustion. Four machine learning models Random Forest (RF), Multivariate Adaptive Regression Splines (MARS), Support Vector Regression (SVR), and Elastic Net (ENET) were employed for modeling and prediction, using environmental covariates such as geomorphometric parameters, climatic variables, and mosaic bare soil indices. Model performance assessment through 10-fold cross-validation revealed that RF consistently outperformed other models, exhibiting the lowest Mean Absolute Error (MAE) values and the highest R-squared (R<sup>2</sup>) scores for both SOC 10 (R<sup>2</sup> 0.79, MAE 0.32%) and SOC 30 (R<sup>2</sup> 0.82, MAE 0.28%). While MARS provided acceptable results, ENET and SVR showed higher Root Mean Squared Error (RMSE) and lower R<sup>2</sup> values, indicating lower accuracy in SOC modeling and prediction. The resulting SOC 10 map displayed a range from 1.73% to 7.76% with a mean SOC content of 2.72%, while SOC 30 exhibited a narrower range (1.22% to 3.13%) with a mean value of 1.73%. This research underscores the effectiveness of machine learning in DSM for predicting and mapping SOC across diverse land cover types, emphasizing the influence of temperature and precipitation on the spatial distribution of SOC content. The findings contribute valuable insights into understanding the potential impact of climate change on the future distribution of SOC in Bohemian uplands.

<sup>2</sup> Centro de Biotecnología, Departamento de Química Analítica e Inorgánica, Facultad de Ciencias Químicas, Universidad de C, CONCEPCIÓN, CHILE

The geological environment (GE) shapes soil formation and characteristics. Soil Spectroscopy's cost-effectiveness and eco-friendliness make it ideal for acquiring extensive datasets to quantify and map soil functions. Despite the focus on broad-scale soil property prediction models, GE-based sectorization supports targeted strategies for soil function management in research and policy context. A sectorization based on GE is expected to improve predictive power of the V-NIRS model. By reducing variability in indirect variables (climate, soil type, texture, pH, etc.) influencing the response variable, in this case, MOS an indicator of soil functioning. We evaluated the performance of the PLS V-NIRS model in a latitudinal transect with 80 sites from Maule to Araucanía regions (35°S-36°S). We compared this performance with the sectorized PLS V-NIRS model based on five different GE present in the studied transect: metamorphic (M), plutonic (P), continental sedimentary (CS), volcanic (V), and volcanic sedimentary (VS). Geospatial information from the geological map of Chile at 1:1,000,000 scale was used. The relationship between GE and MOS, pH, available Ca, and clay content, was determined with ANOVA and Tukey post hoc test with a 95% confidence level. Showing significant statistical differences ( $p < 0.005$ ) in SOM among other studied variables. Additionally, a Principal Component Analysis illustrated the grouping of GE in function of MOS, yielding two components with 72% of the total variance. Comparison results of V-NIRS PLS models demonstrated improved predictive power with sectorization. The PLS model without data treatment for the whole transect presented an  $R^2=99.9$ ,  $R_{val}=0.79$ , and  $R_{cal}=0.80$ , compared to the statistics of M ( $R^2=86.5$ ,  $R_{val}=0.94$ , and  $R_{cal}=0.98$ ), P ( $R^2=99.8$ ,  $R_{val}=0.94$ , and  $R_{cal}=0.96$ ), CS ( $R^2= 59.5$ ,  $R_{val}=0.89$ , and  $R_{cal}=0.95$ ), V ( $R^2=75.8$ ,  $R_{val}=0.84$ , and  $R_{cal}=0.95$ ), and VS ( $R^2=44.5$ ,  $R_{val}=0.98$ , and  $R_{cal}=0.99$ ). These findings affirm the feasibility of sectorizing by GE to comprehend carbon dynamics and to improve predicted C models, becoming a tool to identify soil C resilient zones and formulate targeted mitigation strategies.

### RELATIONSHIPS BETWEEN CARBON CONCENTRATION IN ROOTS AND THE PEDOENVIRONMENT: A STUDY WITH MACHINE LEARNING

C.G.O. BALDI <sup>1</sup>, C.M. MOQUEDACE <sup>1</sup>, L.U.L. SOARES <sup>1</sup>, R.G. SIQUEIRA <sup>1</sup>, M.R. FRANCELINO <sup>1</sup>, C.E.G.R. SCHAEFER <sup>1</sup>, L.C. GOMES <sup>2</sup>, E.I. FERNANDES-FILHO <sup>1</sup>

<sup>1</sup> Laboratório de Geoprocessamento e Pedometria, Department of Soil Science, Universidade Federal de Viçosa, VIÇOSA, BRAZIL

<sup>2</sup> Department of Agroecology, Aarhus University (AU Viborg), VIBORG, DENMARK

Roots play a fundamental role in the formation of soil organic carbon stocks. However, there is still little knowledge about how root carbon concentration responds to the pedoenvironment at a landscape scale. Therefore, our objective was to evaluate the relationships between carbon concentration in roots and the pedoenvironment using machine learning (ML). We use a database of functional root traits, Global Root Traits (GRooT), which compiles harmonized planetary information for global modeling. Root carbon concentration (CCR) was the target variable, with 5006 samples. The explanatory variables were: climate data and net primary productivity (NPP) from Chelsa; soil moisture (0-30 cm) from ERA-5; MODIS normalized difference vegetation index (NDVI); and the NASADEM digital elevation model (DEM). We eliminated redundant variables by correlation and adjusted the random forest (rf) algorithm with repeated cross-validation. We evaluated the model's performance using the concordance correlation coefficient (CCC) and mean absolute error (MAE). Additionally, we compared the rf error to the error of a null model (average). Our model achieved CCC = 0.64 and MAE = 37.02 mgC g<sup>-1</sup>, a 20% smaller error compared to the null model (MAE = 44.9 mgC g<sup>-1</sup>), highlighting the potential of ML techniques in modeling of complex environmental data, such as CCR. When evaluating the importance of predictors, climate stood out (>85%), especially variables associated with extreme events (e.g., temperatures in the hottest month and precipitation in the wettest month). Soil moisture was the second class most of important variables (58.3%). NPP (26.5%), NDVI (13.4%) and DEM (4.2%) were the proxies that contributed least to CCR. The heterogeneity of CCR globally justifies the association of the most important patterns with extreme events, as the size of vegetation is generally limited by water availability and temperature. This, associated with soil texture, modulates moisture levels which, in turn, condition the development of vegetation and, consequently, root biomass. Our study showed that climate and soil humidity significantly modulate CCR at a global level.

### 6.03 129517 - Digital Soil Mapping and Assessment at different scales – Where to go next?

#### ASSESSMENT OF DSM PRODUCTS AT CONTINENTAL SCALE

L. POGGIO, D. ROSSITER, G. GENOVA, B. KEMPEN, L. CALISTO, N. BATJES

ISRIC - World Soil Information, Wageningen, THE NETHERLANDS

Digital Soil Mapping (DSM) products are generated for various regions, nations, continents. Most products include some accuracy metrics, some include assessment of uncertainty. The accuracy and uncertainty metrics typically used for DSM products do not encompass some of the elements that are necessary to assess “fitness-for-intended-use” of a map. For instance, different models can have very similar accuracy metrics but produce different soil-landscape patterns. It is important to be able to evaluate the accuracy of the patterns as well, current accuracy metrics do not do this. Additional metrics could be defined that are able to do this such the ‘area of applicability’, i.e. the area in covariate space where the model learns about relationships based on the training data) and the landscape heterogeneity both in the landscape itself and in covariate space.

In this study we present initial results on how to integrate the elements mentioned above in an assessment of DSM uncertainty at continental scale. The test case is Europe with input observations derived from EU-LUCAS datasets. We use a covariates space that covers the soil forming factors according to the “scorpan” model. We characterise the spatial heterogeneity of the landscape and the covariates space with commonly-used landscape metrics. Based on the results we present some practical recommendations on how to use the above elements in order to develop products for stakeholders that correspond to their intended uses.

**FUNCTIONAL ASSESSMENT OF SOILGRIDS IN THE LIGHT OF AGRICULTURAL APPLICATIONS AND POSSIBLE IMPROVEMENTS.**

L. FERLIN, R. MAZZOLENI, S. EMAMALIZADEH, V. PARAVIZZINI, G. HASANLI, G. BARONI

Department of Agricultural and Food Sciences, University of Bologna, Bologna, ITALY

SoilGrids data has been used to support research activities in several scientific disciplines for regional and global studies. Among others, the success was made by the availability of harmonized data crossing administrative boundaries, uncertainty quantification and a user-friendly interface to explore and download the data. While the spatial resolution was initially too coarse for more specific local studies, e.g., precision agriculture, the higher increasing resolution of the new versions could open the path to new applications and synergies.

In this contribution we show and discuss the assessment of SoilGrids at several locations in Italy focusing on agricultural applications. The assessment is conducted based on regional soil maps and direct soil analysis conducted at the respective sites. The applications cover the use of soil parameters for calibrating soil moisture sensors, harmonizing ground and remote sensing soil moisture products, and delineating agricultural prescription maps. The integration of data collected through remote and proximal soil sensing techniques is explored to enrich the quality of the prediction.

The results show, on the one hand, the valuable information provided by SoilGrids in supporting agricultural applications. On the other hand, additional information available from agricultural studies could be integrated for further improvements of the digital map. Thus, the synergy between global digital soil mapping and precision agriculture could be considered as a valuable approach for further improvements. Standardizing the data collected at the different locations will be a key feature for exploiting these synergies.

<sup>2</sup> National Laboratory for Water Science and Water Safety, Budapest, HUNGARY

Quantitative information on state and flux of water in the critical zone is crucial for various environmental models. The performance of models related to soil hydrological processes relies on the quality and resolution of soil hydraulic input parameters. At the European scale, the 3D soil hydraulic database of Europe at 250 m resolution (EU-SoilHydroGrids) has demonstrated its applicability in numerous studies. A comparable but larger-scale 3D soil hydraulic database, HU-SoilHydroGrids, was developed for Hungary to analyse whether there is room for accuracy improvement compared to the continental maps. This study, supported by various enhancements in the computation process, utilized advanced machine learning methods trained on the national soil hydrophysical dataset to construct pedotransfer functions (PTFs). Additionally, the set of predictors for PTFs was expanded to include additional environmental auxiliary variables. The spatial inference of these derived models utilized 100 m resolution information on primary soil properties from DOSoReMI.hu.

HU-SoilHydroGrids provides information on the most frequently used soil hydraulic properties (water content at saturation, field capacity, wilting point, saturated hydraulic conductivity, and van Genuchten parameters for water retention curve description) with national coverage at a 100-meter spatial resolution down to 2 meters for six GSM standard depth layers.

The results of the study showed that employing PTFs derived on local data, through ensemble models, and applied to both local input soil data and other environmental data yields more accurate soil hydraulic maps compared to global or continental alternatives, including the widely used EU-SoilHydroGrids.

The resulting 3D soil hydraulic database is currently available through the National Laboratory for Water Science and Water Safety for project partners to assess its functional performance in describing hydrological processes.

#### EXAMINATION OF THE ATSAVI INDEX IN THE CASE OF DIFFERENT NUTRIENT SUPPLY AND TILLAGE SYSTEMS IN A SMALL PLOT LONG-TERM FIELD EXPERIMENT WITH A MULTISPECTRAL UAV

A. ILLES, A. SZÉLES, T. RÁTONYI, P. FEJÉR, E. HARSÁNYI, P. RAGÁN, J. NAGY, C. BOJTOR

Institute of Land Use, Engineering and Precision Farming Technology, University of Debrecen, Debrecen, HUNGARY

The aim of this research was to use remote sensing used in cultivation technology to learn about our soil during the maize sowing period. Soil mapping with remote sensing will be an even more important technology in the future, because farmers need to know the exact soil parameters before and during the growing season. In this study, the data of two different long-term experiments were used to determine ATSAVI index from the soil surface without vegetation. The first experiment is aimed at examining the nutrient supply reaction of different maize hybrids in the same place with the same parameters for more than 40 years. The other experiment compares different tillage methods. During the analysis, the non-soil parts, such as weeds, maize and stem residues, were filtered out and thus the test was performed only on the soil surface. Multispectral UAV was used with RTK system with the remote sensing. RTK was used for the flight and shooting photos. The experiments were carried out at the University of Debrecen, Látókép Experimental Station. The experiment site was an excellent area for field experiments and has suitable agrotechnical biological and soil conditions. The soil type of the experiment site has homogenous calcareous chernozem. The elevation optimisation was turned on during the flight. Adjusted transformed soil-adjusted vegetation index was used for the detection and the analyses were made in QGIS and R studio software. The ATSAVI vegetation index was higher in the strip tillage than the conventional winter plough and reduced soil tillage system (ripening tillage). The amount of nutrient supply affected the value of ATSAVI differently. In the first 3 nutrient supply levels, the value was lower than the higher nutrient supply. At the highest nutrient level, the values were higher as a result of high-dose nitrogen supplementation than as a result of lower nitrogen supplementation. Based on these results, the ATSAVI index depends on the nutrient supply and the soil tillage system.

#### EFFICIENT SAMPLING FOR PREDICTIVE NUTRIENT MAPPING IN FARM-SCALE CROP MANAGEMENT

D. ZIZALA, J. SKALA, R. MINARIK

Research Institution for Soil and Water Conservation, Prague, CZECH REPUBLIC

Plant nutrition and balanced fertilization require very accurate information from the field at the lowest possible cost and therefore limited number of samples. It is therefore essential to optimise sampling schemes. The aim of this study is to compare widely used sampling schemes combined with variable sample size for the prediction of common soil macronutrients. Conditional Latin hypercube sampling (cLHS), feature space coverage sampling with k-means (FSCS) and simple random sampling (SRS) were compared. The effect of sampling scheme and sample size on the accuracy of predicted nutrient maps was investigated in a real case study field (35 ha) with heterogeneous soil properties. A total of 200 training points were placed in 6 grids: cLHS and FSCS with 10, 30 and 60 samples, corresponding to 1 sample per 3, 1 and 0.5 ha, respectively. For the numerical experiment with different sampling frequencies, all 200 training samples were interpolated into a set of nutrient maps, which were considered as an error-free dataset for both calibration and validation samples included in the predictive modelling. Sampling grids with variable sample sizes from 2 to 60 were created using SRS, cLHS and FSCS in combination with a pragmatic set of environmental covariates. Each network of each method was automatically generated 100 times using the same algorithm settings. These were used to make predictions using the covariates. The performance of the models was monitored.

The results show the advantage of using FSCS, which shows both less variation in prediction accuracy compared to SRS and cLHS and better results with sparse sampling.

**EXPLORING THE SPATIAL VARIABILITY OF SOIL PROPERTIES USING GEOSTATISTICAL TOOLS ON A BLACKBERRY (*RUBUS FLORIBUNDUS* C. PRESL) FARM IN PAMPLONA, NORTE DE SANTANDER, COLOMBIA**

A.F. GONZALEZ PEDRAZA<sup>1</sup>, Y.M. MORALES VILLASMIL<sup>1</sup>, A.F. GONZALEZ PEDRAZA<sup>2</sup>, J.C. REY BRISNA<sup>3</sup>

<sup>1</sup> University of Pamplona, PAMPLONA, COLOMBIA

<sup>2</sup> University of Pamplona, PAMPLONA, COLOMBIA

<sup>3</sup> Central University of Venezuela, MARACAY, VENEZUELA

The cultivation of blackberries in Pamplona is distinguished by its climatic adaptability, resistance to pests, and high acceptance for fresh consumption. Despite its significance, there is limited information about the soil conditions in which the cultivation grow up. In this study, we analyzed the spatial variability of soil properties employing geostatistical tools. A systematic sampling of 26 points yielded a total of 52 soil samples from depths of 0-20 cm and 20-40 cm. Texture, gravimetric moisture (GM), bulk density (BD), real density (RD), total porosity (TP), mechanical penetration resistance (MPR), organic matter (OM), pH, and electrical conductivity (EC) were evaluated. A univariate statistical analysis described soil properties, and maps of spatial variability were generated through semivariance calculation and ordinary kriging interpolation. The soil texture was loamy-sandy, with sand percentages exceeding 65% at both depths, explaining the low moisture percentages (< 28%). The mean BD was 1.61 and 1.63 g/cm<sup>3</sup>, while RD was 2.23 and 2.31 g/cm<sup>3</sup> for 0-20 cm and 20-40 cm, respectively. The average TP was 32.48% and 30.86%, and for the MPR (kg/cm<sup>2</sup>) was 1.54, increasing to 2.06 at 0-20 cm and 20-40 cm, respectively. Soil pH varied from 5.32 at 0-20 cm and 5.03 at 20-40 cm. The soils did not exhibit salinity issues (EC<50 µs/cm). The average OM percentage was 17.72 at 0-20 cm, decreasing to 14.48 at 20-40 cm. Spatial variability of soil properties at 0-20 cm was considered moderate, except for OM, which exhibited high spatial variability. At 20-40 cm, there was a more pronounced spatial variability, with GM, pH, and OM varying significantly across the farm. At 0-20 cm, BD and MPR showed moderate spatial dependence. OM, RD, and TP exhibited strong dependence, while GM showed low dependence. At 20-40 cm, GM, BD, TP, and MPR displayed strong dependence, while RD exhibited moderate dependence. Ordinary kriging interpolation accurately estimated variables in unsampled or topographically challenging areas, with minimal margin of error.

Table 1. Distribution of soil particle size on the farm.

Variables	Depth (cm)	n	Mean	Minimum	Maximum	CV
Clay (%)	0-20	26	15,41 ± 6,06	6,2	27,8	39,33
	20-40	26	15,79 ± 5,33	2,35	24,15	33,73
Silt (%)	0-20	26	18,4 ± 4,95	7,5	28,65	26,91
	20-40	26	18,95 ± 6,5	7,5	32,5	34,32
Sand (%)	0-20	26	66,54 ± 9,58	50,15	81,5	14,4
	20-40	26	65,03 ± 10,22	47,2	82,2	15,72
Textural class	0-20	26	Sandy loam			
	20-40	26	Sandy loam			

Mean values ± standard deviation. CV: Coefficient of variation; n: number of samples

#### SPATIAL DISTRIBUTION OF ELEMENTS IN LATERITIC SOILS FROM A RARE SIDERITE CARBONATITE FORMATION IN THE BRAZILIAN AMAZON USING REMOTELY SENSED DATA AND TOPOGRAPHIC ATTRIBUTES

N. RODRIGUES<sup>1</sup>, H. RODRIGUES<sup>1</sup>, M. MANCINI<sup>2</sup>, H. PINHEIRO<sup>1</sup>, W. CARVALHO JUNIOR<sup>3</sup>, Z. LIBOHOVA<sup>4</sup>, P. OWENS<sup>4</sup>

<sup>1</sup> Federal Rural University of Rio de Janeiro, Rio de Janeiro, BRASIL

<sup>2</sup> Federal University of Lavras, Minas Gerais, BRASIL

<sup>3</sup> EMBRAPA SOLOS, Rio de Janeiro, BRASIL

<sup>4</sup> U.S. DEPARTMENT OF AGRICULTURE, Bentonville, EUA

Carbonatites are considered rare, their distribution in the crust is minimal at a global level and they have a high economic value. The Brazilian Amazon held the Morro dos Seis Lagos carbonatite complex, considered to be one of the largest known Nb deposit, with an estimated reserve around 2.9 billion tons of niobium. The occurrence of siderite carbonatite on highly weathered geomorphic surfaces has given rise to a thick lateritic crust, which hosts trace minerals containing elements with economic potential. The goal was to study the laterization process undergoing on a rare siderite carbonatite parent material by assessing the spatial distribution of Fe<sub>2</sub>O<sub>3</sub>, Nb, TiO<sub>2</sub>, and W using machine learning. Amount of 341 samples including soil, sediment, and rock material were gathered from the Geological Survey of Brazil (CPRM). Covariates included remotely sensed data collected from Sentinel-2 MSI, Sentinel-1A and Advanced Spaceborne Thermal Emission and Reflection Radiometer (ASTER), and topographic attributes calculated from a 20-m digital elevation model (DEM). The modelling procedures were performed using the Multivariate Adaptive Regression Spline (MARS), Support Vector Machine with radial kernel (SVMRadial), and Random Forest (RF) algorithms. The optimal covariates for modeling were chosen using Recursive Feature Elimination (RFE). The most relevant covariates for the distribution of the elements contained in the laterites were evaluated using the RFE results. The models performed better in predicting W ( $R^2 = 0.32$ ), Fe<sub>2</sub>O<sub>3</sub> ( $R^2 = 0.24$ ), TiO<sub>2</sub> ( $R^2 = 0.14$ ) using the RF model, while the MARS models showed greater ability in predicting Nb ( $R^2 = 0.10$ ). Best results for MnO ( $R^2 = 0.22$ ) were found when using SVMRadial. The importance metric provided by the RFE indicated that terrain attributes exert a greater influence on the spatial distribution of the elements studied compared to remote sensing spectral indices, thus indicating that the relief may be one of the main drivers of the pedological processes responsible for the formation of laterites in the area.

#### THE CREA SOIL MAP ARCHIVE AND DIGITIZATION OF CULTURAL HERITAGE PRODUCTS

G. L'ABATE <sup>1</sup>, A. ORLANDINI <sup>1</sup>, S. LO FARO <sup>2</sup>

<sup>1</sup> CREA, Agriculture and Environment, Firenze (FI), ITALY

<sup>2</sup> SYSTEMCART S.r.l., Roma (RM), ITALY

Historical soil maps are cultural heritage products worth to be preserved according to the principles of open data (FAIR - findable, accessible, interoperable, and reusable).

The CREA collection gathers hundreds of maps surveyed at various scales, from the finest detail (1:1,500) to the national scale (1: 3,125,000).

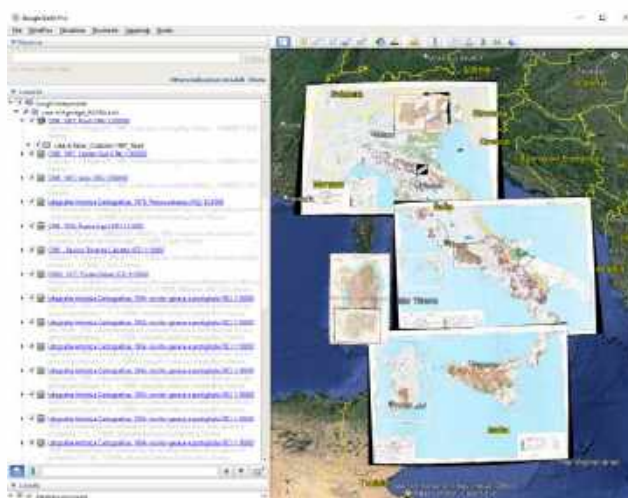

Their first digitalization has been realized within the GO PROSIT project, for the Tuscany Region, and recently within the Agridigit - SUVISA project for the whole Italian collection. Paper documents were digitized both in PDF, and geoTIFF formats.

For Tuscany, the work included 52 documents realized between 1969 and 2012 by 13 different institutions, both Italian and International, with the involvement of over 100 authors. Additionally, 18 of these maps were integrated into a web application for Digital Agriculture (<https://app.geapp.net/>), for free use by all Tuscan agricultural farms.

For Italy, the work interested initially 36 paper documents published between 1954 and 1985 by 14 different institutions, with the involvement of over 55 authors.

Digitized documents have been published on a Geoserver platform to expose spatial data source adopting open standards (<https://crea-it-geoserver.azurewebsites.net/>). GeoServer implements several Open Geospatial Consortium protocols including Web Map Service (WMS), Web Feature Service (WFS), Web Coverage Service (WCS) and Web Map Tile Service (WMTS). The platform allows also to manage Layer groups to download spatial data according to several formats, among which GoogleEarth file (KML). Furthermore, Open Geospatial Consortium protocols allow Interoperable reuse of data. For instance, the complete dataset might be accessed directly within the QGIS software without the need to download data by the WMS protocol.

Although maps vary significantly in quality and purpose of use, their digitization allows this informational heritage to be digitally preserved, public, accessible, and directly usable by means of several GIS software. Digitalization of maps is still going on and this work is thought as a contribution on how to spread ancillary maps adopting technical tools, protocols, and facilities.

#### THREE-DIMENSIONAL MAPPING OF SOIL ORGANIC MATTER AT REGIONAL-SCALE IN THE BLACK SOIL AREAS WITH THE FUSION OF PROXIMAL AND REMOTE SENSING DATA USING INLA-SPDE

W. JI <sup>1</sup>, Y. YAN <sup>1</sup>, B. LI <sup>1</sup>, H. YE <sup>1</sup>, Y. HUANG <sup>1</sup>, Z. SHI <sup>2</sup>, S. CHEN <sup>3</sup>, X. HOU <sup>1</sup>, T. REN <sup>1</sup>, H. ZHOU <sup>1</sup>

<sup>1</sup> College of land Science and Technology, China Agricultural University, Beijing, CHINA

<sup>2</sup> College of Environmental and Resource Sciences, Zhejiang University, Hangzhou, CHINA

<sup>3</sup> ZJU-Hangzhou Global Scientific and Technological Innovation Center, Hangzhou, CHINA

Accurate 3D mapping of SOM is essential for informed agricultural practices and environmental conservation, particularly within Black Soil regions. However, current SOM mapping methodologies lack genuine 3D mapping approach, which means soil properties can be precisely quantified and uncertainty analyzed at any given coordinate (x, y, z) within a soil's volumetric matrix. Previous relevant studies predominantly rely on remote sensing as the primary source for environmental covariates, which leads to a significant limitation: the same set of remote sensing data was used across various soil depths, failing to accurately represent the unique environmental factors influencing each layer. To bridge these gaps, this study aims to incorporate depth-specific environmental factors obtained from a proximal visible-near infrared (vis-NIR) spectrometers to achieve more accurate 3D SOM mapping using INLA-SPDE in Bayesian space stochastic simulation.

In this study, a total of 481 soil samples were collected (0-100 cm depth, at 10 cm intervals) from 49 locations in Lishu County, Northeast China. The SOM content was measured using standard laboratory methods, and Vis-NIR spectra were acquired after the samples were air-dried and ground. Meanwhile, remote sensing factors including climate, soil, terrain and vegetable factors were also collected. Different combination of these proximal and remote sensing data were employed to model SOM in 3D using the INLA-SPDE algorithm. The evaluation metrics revealed the best prediction with  $R^2 = 0.89$  and  $RPD=3.03$  was obtained with the fusion of both proximal and remote sensing data, while a slightly lower accuracy ( $R^2 = 0.86$  and  $RPD=2.67$ ) was obtained when adding the vis-NIR, only. Both two working scenarios showed superior performances than the use of 3D-IDW ( $R^2=0.43$ ,  $RPD=1.15$ ). We thus suggested the addition of Vis-NIR spectra to environmental covariates to enhance the accuracy in 3D SOM mapping. The framework this study created might bring benefit for sustainable land management practices and carbon sequestration potential evaluation in the context of global climate change mitigation strategies.

<sup>2</sup> Department of Environmental Science, The University of Arizona, Tucson, USA

The accurate characterization of soil hydraulic properties is crucial for quantifying the dynamic exchange of mass and energy between the Earth's land surface, the groundwater, and the atmosphere. Current large-scale digital maps of the soil water retention curve (SWRC) are typically developed indirectly and in a two-step process: i) the development of pedotransfer functions (PTFs) that establish relationships between basic soil properties such as textural fractions, bulk density, and organic matter content and parameters of well-known SWRC models, and ii) the application of these PTFs to basic soil property maps at different scales. While digital soil mapping (DSM) methods have shown promising results for various soil properties, their potential for direct mapping of the SWRC has not been explored. This presentation introduces a novel, physically-constrained machine learning approach designed for the direct mapping of the complete SWRC. Unlike in previous studies, our new approach does not rely on PTFs and is not limited to a specific form of the SWRC, thereby reducing uncertainties. The new approach leverages the universal approximation theorems of neural networks and is constrained by the fundamental functional properties of a SWRC. Applying this new method to 1261 soil profiles across Denmark, encompassing 4747 measured SWRCs, reveals its superior performance over established methods. The new approach allows for the aggregation of datasets with limited measured SWRC points, a capability not achievable with other methods. Additionally, it provides meaningful extrapolated values beyond the range of measured SWRC data, owing to the physical constraints imposed on the model.

<sup>4</sup> University of Bucharest, Faculty of Geography, 1 Nicolae Balcescu Street, 010041, Bucharest, Romania, BUCHAREST, ROMANIA

Humanity's food security can be considerably threatened by multiple land degradation processes (or land multi-degradation), which can act simultaneously across global productive (arable) soils. However, the spatial footprint of land processes that act convergently in arable landscapes is not sufficiently understood at global scale. Consequently, here we analyze the convergence of five major degradative processes (aridity, soil erosion, vegetation decline, soil salinization, and soil organic carbon decline) in global arable lands, using large-scale spatial databases that were modelled using various GIS (Geographic Information System) techniques. Our worldwide examination of co-occurring processes showed a complex pattern of arable land multi-degradation (in terms of number and types of converging processes, explored at pixel level), largely dominated by the interaction between aridity and soil erosion across the planet. Our global findings can be useful for a better governance of soils exposed to various environmental threats, and thus for a more efficient achievement of soil-related sustainable development goals.

#### KAKHOVKA DAM DAMAGE CONSEQUENCES MAPPING AND IMPACT ASSESSMENT ON BLACK SOILS IN THE SOUTH OF UKRAINE

Y. ZALAVSKYI

NSC Institute for Soil Science and Agrochemistry Research named after O.N.Sokolovsky, Kharkiv, UKRAINE

The biggest man-made disasters caused by Russian armed aggression is the Kakhovka Dam explosion on June 6, 2023. The dam destruction consequences were complete and partial soil flooding; settlements flooding, groundwater pollution, irrigation stopping and functioning ecosystem changes, formed for 70 years of the Kakhovka reservoir (lake) existence.

To carry out a GIS analysis of the assessment impact on the soil we used Sentinel-2 remote sensing data in a time-varying period from the normal state to the maximum lands flooding. The moisture index made it possible the contours deciphering of fully and partially flooded. Through GIS analysis, were established the limits of the Dnipro and Inhulets rivers valleys flooding. For the impact assessment on the soil, the flooding data was combined with soil regional maps. Total estimated area of flooding is 83000 ha.

However, when assessing the overall impact of negative consequences, it is necessary to take into account the direct and indirect impact. Kakhovka lake had a strong influence on large irrigation systems with black soils. It's important to consider the probable pollution of irrigation systems (IS) due to the Inhulets River valley flooding. Many hectares of agricultural land may suffer significant degradation due to lack of irrigation and sewage pollution.

The area of negative consequences impact was estimated by map – 3.67 mil. ha. It includes: directly flooded lands, drained lands, destroyed and non-functioning IS, polluted IS, water consumption zones for social needs, etc.

More than 30 soil types were in the influence zone: Chernozems, Dark Gray podzolized, Dark Chestnut and Meadow Chernozem soils, which are Black soils according to the FAO classification . Their area is about 2.5 mil.ha.

However, there is positive point can be highlighted. When was draining the Kakhovka lake bottom, new, so-called subaquatic soils appeared. Soils flooded since the 1950s and covered with a thicker layer of silt. Among them are buried black soils. The total area of subaquatic soils is 170000 ha.

#### GEOSPATIAL MODELING SALT-AFFECTED SOILS IN KAZAKHSTAN.

A. YERSHIBULOV<sup>1</sup>, C. OMUTO<sup>2</sup>, K. PACHIKIN<sup>1</sup>

<sup>1</sup> Kazakh Research Institute of Soil Science and Agrochemistry named after U.U.Uspanov, Almaty, KAZAKHSTAN

<sup>2</sup> University of Nairobi, Nairobi, KENYA

Salt-affected soils, a pervasive issue in Kazakhstan, exert considerable constraints on agricultural productivity and environmental equilibrium. This abstract introduces a geospatial modeling initiative aimed at comprehensively assessing and mapping salt soils in Kazakhstan. The study's primary goal is to provide invaluable insights that contribute to informed decision-making in sustainable land use planning and improved agricultural practices.

The methodology integrates advanced geospatial techniques, including remote sensing, GIS mapping, and soil sampling data. These tools collectively enable the creation of a detailed and accurate representation of the distribution and severity of salt-affected soils across different regions in Kazakhstan.

Our findings shed light on the spatial patterns, dynamics, and key influencing factors contributing to the occurrence of salt-affected soils. By understanding the extent and severity of salt soil distribution, stakeholders in agriculture, environmental management, and policy formulation can develop targeted strategies to mitigate the impact of salinity on soil health and crop production.

This geospatial modeling approach serves as a powerful tool for predicting and managing salt-affected soils, facilitating evidence-based decision-making for sustainable land use practices. The insights gained from this study will contribute to the development of tailored solutions, empowering Kazakhstan to address the challenges posed by salt-affected soils and enhance the resilience of its agricultural landscapes.

<sup>2</sup> Department of Soil Science, Universidade Federal de Viçosa, VIÇOSA, BRAZIL

<sup>3</sup> Department of Forestry Engineering, Universidade Federal de Rondônia, ROLIM DE MOURA, BRAZIL

<sup>4</sup> Department of Agroecology, Aarhus University (AU Viborg), VIBORG, DENMARK

Soil organic carbon (SOC) stocks play a central role in mitigating climate change, due to their significant quantity in terrestrial ecosystems. The methods and scales used to inventory these stocks can significantly impact estimates. Therefore, our objective was to model SOC stocks in the state of Rondônia, Brazil, using machine learning techniques and compare them with national (Gomes; Vasques) and global (SoilGrids) estimates. We used 2794 soil profiles (11.76 profiles per 1000 km<sup>2</sup>) to model SOC stocks in a 0-30 cm layer. Soil density was estimated using pedotransfer in profiles where no information was available. We used data derived from the SCORPAN model to compose our set of explanatory variables, totaling 77 predictors. We eliminated redundant and unimportant predictors using the recursive feature elimination technique. We employed the random forest (rf) algorithm and fitted the model with 80% of the data, reserving the remaining 20% for testing, performing 100 runs. Our estimates presented a mean absolute error (MAE) of 19.6 MgC ha<sup>-1</sup> and root mean square error (RMSE) of 30.4 MgC ha<sup>-1</sup>, while national and global models presented MAE = 41.1 MgC ha<sup>-1</sup> and RMSE = 63.5 MgC ha<sup>-1</sup>. Our estimates revealed an overestimation of national and global maps of SOC stocks (100 MgC ha<sup>-1</sup>) in the central region and an underestimation (400 MgC ha<sup>-1</sup>) in the southern region of Rondônia. These results are associated with regions with lower and higher concentrations of SOC, respectively. Therefore, we emphasize the importance of regional soil sampling and mapping, especially SOC, to identify storage hotspots, avoiding mistaken decisions by public policy makers that could intensify environmental problems. While national and global maps provide initial insights into SOC stock, we highlight that regional sampling and mapping are essential for more accurate assessment. Our results show how regional modeling, with local sampling, can improve SOC stock estimates, contributing to the quantification of soil carbon budgets.

### SOIL CONSERVATION IN OLD VINEYARDS: WHAT IS THE OPTIMAL LEVEL OF INTERVENTION - IS LESS MORE?

J. NINKOV<sup>1</sup>, D. JAKSIC<sup>2</sup>, J. VASIN<sup>1</sup>, S. JAKSIC<sup>1</sup>, S. MILIC<sup>1</sup>, I. BRADIC<sup>3</sup>, V. PEROVIC<sup>4</sup>

<sup>1</sup> Institute of Field and Vegetable Crops, the National Institute of the R. of Serbia, Laboratory for Soil and Agroecology, Novi Sad, SERBIA

<sup>2</sup> Institute for Science Application in Agriculture, Belgrade, SERBIA

<sup>3</sup> Centre for Viticulture and Oenology Nis, Office in Trstenik, Nis, SERBIA

<sup>4</sup> Institute for Biological Research Sinisa Stankovic, the National Institute of the R. of Serbia, University of Belgrade, Belgrade, SERBIA

In viticulture, the soil can be strongly influenced, compared to the possibilities of anthropogenic influence on other abiotic factors of terroir, such as climate. Old vineyards, aged over 40 years, are characterized by small areas, rare grapevine varieties, lower vigour, and yields. Old vines have a deeper, more developed root system, traditionally believed to have improved access to nutrient and water reserves, sustaining themselves with minimal human intervention. The preservation of old vineyards is invaluable for the heritage of wine-growing areas, enhancing the conservation of genetic biodiversity.

The study focused on six old vineyards identified as candidates for conservation in central Serbia, within the Tri Morave wine-growing region/PDO, known for its rich cultivation history. These vineyards, planted between 1930 and 1979, feature local grapevine varieties including Prokupac, Tamjanika, and Kavcina. Pedological investigations revealed two soil types: Eutric Cambisol (Ochric) and Haplic Vertisol. Mechanical composition was found to be linked to soil type, while pH and carbonate content were associated with the micro location. However, the content of organic matter and readily available nutrients P and K showed significant anthropogenic influence, indicating a notable deficiency in these elements. The soil is well supplied with accessible microelements (Zn, Fe, Mn), but has a very low boron content. Total copper content was high, exceeding 100 ppm at five locations due to prolonged use of copper-based fungicides. Insight into agricultural practices revealed imprecise record-keeping by owners, with old vineyards commonly left without fertilization, while pesticides are still applied.

This research indicates the degradation of old vineyard soil, emphasizing the need for deliberate intervention. Vulnerable vineyards like these deserve all contemporary available nurture to ensure their survival. In the conservation process, non-invasive 'green' measures must be implemented aiming to restore soil health. It is necessary to avoid copper-based treatments and maintain continuous soil monitoring. Critical grapevine nutrition can be achieved through judicious foliar application, avoiding deep fertilizer incorporation with the aim of preserving undisturbed soil.

### IMPACT OF INTRA-VINEYARD SOIL VARIABILITY ON VINEYARD IRRIGATION TRIAL

S. PRIORI<sup>1</sup>, G. PALAI<sup>2</sup>, G. CARUSO<sup>2</sup>

<sup>1</sup> University of Tuscia, Department of Agriculture and Forest Sciences, Viterbo, ITALY

<sup>2</sup> University of Pisa, Department of Agriculture Food and Environment, Pisa, ITALY

Proper irrigation management is essential to modulate the water status of the grapevine and thus achieve high fruit quality. The effect of irrigation on the grapevine also depends on the physical and hydrological characteristics of the soil. The aim of this work was to test the effect of intra-vineyard soil spatial variability in a trial with different types of irrigation, namely Full (FI, 100% of crop evapotranspiration, ETC), deficit irrigation (DI, 40% of ETC), and Rainfed (RF, only precipitation).

The experiment was conducted in a commercial vineyard (cv. Sangiovese) located in Suvereto, Tuscany, Italy. The soil was firstly mapped by an Electromagnetic Induction (EMI) sensor, and then described by manual augerings in 9 sites. It was classified as Eutric Cambisol (Loamic), with a texture variable from Sandy Loam to Sandy Clay Loam (clay from 19 to 30%), common small and medium stoniness, and moderate redoximorphic mottles in depth (50-80 cm) in most of the augerings. According to soil mapping, augerings description and analysis, the soils of the vineyard were subdivided into 3 groups (A, B, and C), where B show the lowest apparent electrical conductivity measured by EMI sensor, around 18 mS/m versus 24-27 mS/m of zone A and C. Significant differences in Leaf Area Index (LAI) were found between the three irrigation regimes in zone A (from 0.51 to 0.74) and zone C (from 0.52 to 0.79), but not in zone B (from 0.55 to 0.57), where the lowest LAI values of FI and DI were measured. Soil B seems to have some limitations of grapevine growth and grape yield, which can overcome the effects of irrigation.

### A NUMERICAL CLASSIFICATION APPROACH FOR THE ON-FARM MAPPING OF VINEYARD SOILS: GOODALL'S SIMILARITY INDEX AND GEOSTATISTICAL MODELING FOR THE SOIL MAP OF THE KOZLOVIC WINERY (ISTRIA, CROATIA)

G. BRAGATO <sup>1</sup>, C. LOZANO FONDON <sup>2</sup>, S. AMADEO <sup>3</sup>, E. RONCHIN <sup>1</sup>

<sup>1</sup> CREA, Gorizia, ITALY

<sup>2</sup> CREA, Firenze, ITALY

<sup>3</sup> VITENOVA SRL, Ronchis (UD), ITALY

Conventional soil survey combined with soil suitability evaluation have allowed a better management of many wine-growing districts and individual wineries. The successful results of this approach rely on the ability to describe the three-dimensional distribution of soils units in space. A weakness, however, is the subjectivity introduced by the tacit knowledge that surveyors acquire during the auger-boring campaign and exploit to understand the spatial distribution of subsurface soil horizons. We sought to improve the accuracy of on-farm soil mapping by reducing the surveyor's subjectivity using Goodall's similarity index, one of three indices we have tested in previous studies for the multivariate analysis of mixed data.

The survey concerned 54-hectare vineyard of the Kozlovic winery in Momjan (Istria, Croatia) located in an undulating hilly landscape on Eocene Flysch at 110-150 m above sea level. A total of 66 locations were selected using the spatial coverage design of the R package spcosa. In the field, the morphological characteristics to a depth of 100 cm were recorded and one sample per horizon collected.

Goodall's index was determined with the program simil. Pairwise similarities were independently calculated for each variable; then they were combined by Fisher's transformation for continuous and discrete probabilities. The resulting pairwise similarity matrix was partitioned into homogeneous groups with the help of the software MATEDIT, and group centroids analysed with geostatistics to map the soil types of the farm.

The survey identified four soil types – from Calcaric Regosols to Vertic Calcaric Cambisols – that were distributed according to an altitudinal sequence influenced by erosive phenomena and partially masked by past slope arrangements. The resulting similarity values made it possible to map the soil types in detail and, at a later stage, to identify representative points where soil monoliths were extracted for a better characterization, which, suitably prepared, are now a wealth of knowledge for visitors to the winery, visually connecting wine production with the soils that support it.

### ANALYSIS OF THE CHANGE IN SOIL DEPTH IN A VITICULTURAL AREA OVER THE LAST DECADES, CARRIED OUT AS PART OF THE CARG PAVIA PROJECT

A. GIAROLA <sup>1</sup>, C. MEISINA <sup>1</sup>, P. TAROLLI <sup>2</sup>, F. ZUCCA <sup>1</sup>, M. BORDONI <sup>1</sup>

<sup>1</sup> Department of Earth and Environmental Sciences, University of Pavia, Pavia (PV), ITALY

<sup>2</sup> Department of Land, Environment, Agriculture and Forestry, University of Padova, Agripolis, Legnaro (PD), ITALY

In areas of agroeconomical significance, the depth of soil available for cultivation can be negatively impacted by the mechanical action of agricultural machinery.

Multiple vineyard management techniques exist, including (a) Tillage and Total Tillage (T/TT; tillage up to 6 times/yr); (b) Permanent Grass Cover (PGC; no tillage); (c) ALternating tillage-grass (ALT; tilling every other row).

In the Rio Vergombera catchment (Canneto Pavese, PV), an area of 0.54 km<sup>2</sup> belonging to the CARG Pavia project, three main land uses are currently present: (a) vineyards managed through T/TT, (b) areas cultivated as vineyards in 2009 which have since spontaneously become woodlands and (c) woodlands which have existed prior to 2009.

At this location, no significant topographical or geotechnical differences are present, however the soil depth between the three aforementioned land uses varies: the average (minimum and maximum in brackets) are (a) 0.47m (0.27-1.5), (b) 1.23m (0.98-1.8) and (c) 1.57m (1.12-1.76), as measured in 2022, in 24, 6 and 3 locations respectively.

Since the usage of machinery in vineyards has been linked to higher erosion rates compared to areas where tillage was not practiced, it is plausible that the soil depth currently present older woodlands (1.57m) was the depth originally present in all land uses, which had decreased to 1.23m in all T/TT vineyards by 2009. The vineyards which were abandoned then still have similar soil depths, while this value decreases to an average of 0.47m in areas in which T/TT managements are still practiced.

In this area, intense rainfall events have caused, in the last decades, nearly yearly erosive events, which have been to blame for the formation of rills and for the transportation of soil onto the nearby street in correspondence of T/TT vineyards exclusively.

To reduce the soil loss and preserve fertility, the adoption of vineyard management techniques linked to reduced erosion rates compared to T/TT, such as ALT and PGC, could be preferable.

### ASSESSMENT OF GRAPEVINE ADAPTATION AND SOIL-BASED ECOSYSTEM SERVICES UNDER CURRENT AND CLIMATE CHANGE SCENARIOS

A. BASILE, R. ALBRIZIO, M. BANCHERI, A. BONFANTE, M. BUONANNO, R. DE MASCELLIS, A. ERBAGGIO, P. GIORIO, N. OREFICE, A. VITALE

National Council of Research (CNR) - Institute for Mediterranean Agricultural and Forest Systems (ISAFOM), Portici, ITALY

Vineyards are complex agro-ecosystems that display significant spatial and temporal variability owing to their sparse and heterogeneous canopies. This research is part of the 'Integrated Climate Change Risk Modelling and Management - Ensemble of Tailored Models for Predicting Crop and Forest Productivity and Land Vulnerability under Different Climate Scenarios' project, which is a component of the National Center for Technology in Agriculture AGRITECH - Spoke 4. The study implements a multidisciplinary approach to investigate the behaviour of 'Aglianico' vines grown on two different soils in a high-quality wine production area in the Campania region (Italy). The focus is on the effects of climate change on production, quality, and ecosystem services provided by the vineyard system

The study is divided into four phases. 1. Functional homogeneous zones by combining information from the digital terrain model, NDVI by remote, EMI soil scanning, and classical soil pedological survey were defined; 2. Two years of monitoring of plants (leaf area index, leaf water potential), soil (soil water content by TDR, ECa scanning), grape quality (weight, volume, density, sugar, pH) and climatic variables; 3. Calibration/validation of a process-based model for the water balance in the soil-plant-atmosphere system; 4. Assessment of grapevine adaptation and soil-based ecosystem services under current and climate change scenarios.

Results of phase 1 and preliminary results related to phases 2, 3 and 4 are reported.

**Keywords:** climate change scenarios, water balance, process-based model, soil-based ecosystem services

### SR-VITIS: A USER-FRIENDLY TOOL TO SUPPORT FARMER IN ROOTSTOCK SELECTION

A. ORLANDINI <sup>1</sup>, G. VALBOA <sup>1</sup>, S. PELLEGRINI <sup>1</sup>, R. PERRIA <sup>2</sup>, A. LAGOMARSINO <sup>1</sup>, N. VIGNOZZI <sup>1</sup>, M.C. ANDRENELLI <sup>1</sup>

<sup>1</sup> CREA-Centro Ricerca Agricoltura e Ambiente (CREA-AA), Firenze, ITALY

<sup>2</sup> CREA-Centro di Ricerca Viticoltura e Enologia (CREA-VE), Arezzo, ITALY

This study presents the development of a user-friendly Decision Support System (Vitis) aiming to enhance farmers' awareness and support them in management choices by using programming potential.

The choice of rootstock is of great importance when planning a new vineyard. The rootstock allows to modulate the plant response, considering soil conditions, compatibility with the cultivar and production target. The Suitable Rootstock (SR) module in Vitis is developed exclusively using the Python programming language to ensure consistency and compatibility across all functionalities, such as data collection, analysis, visualization, and management. The Graphical User Interface (GUI), created with Kivy and KivyMD frameworks, is available in both desktop and mobile versions.

Starting from a set of 17 rootstocks (K5BB, SO4, 420A, 1103P, 110R, 140Ru, 101.14, 196.17, Gravesac, 41B, Fercal, M1, M2, M3, M4, 775P, 779P), identified among the most widespread in Europe, the expert system set up within SR-Vitis excludes rootstocks deemed unsuitable on a bibliographical basis, with respect to the actual pedoclimatic characteristics of the vineyard. Soil properties are entered manually by the user, and concern total limestone, salinity, pH, soil rooting depth, texture, and skeleton. The expert system also requires the insertion of the risk level with respect to stagnation and water stress phenomena, both split into three quality classes, chosen by the user according to his experience.

The output of SR-Vitis consists in the set of rootstocks considered most appropriate for the selected pedoclimatic characteristics of the area of interest. An example of application of the DSS to a farm representative of Chianti Classico area is illustrated.

The introduction of SR-Vitis will provide sector operators with practical and immediately applicable tool for optimized resource management and improved planning of new vineyards.

In the future, the system potentiality will be expanded through upgrades, new functional modules for vineyard management and integration with database. These improvements will make the DSS even more valuable for the vine-growing sector.

### CRITICAL LEVELS OF METAL TOXICITY IN NATIVE SPECIES IN VINEYARDS

A. TASSINARI<sup>1</sup>, L. MORSCH<sup>2</sup>, F. NUNES<sup>1</sup>, G. PERIPOLLI<sup>1</sup>, T. ANDREOLLI<sup>1</sup>, J. MOURA-BUENO<sup>1</sup>, G. BRUNETTO<sup>1</sup>

<sup>1</sup> Federal University of Santa Maria, SANTA MARIA, BRAZIL

<sup>2</sup> Federal University of Santa Catarina, Florianópolis, BRAZIL

Successive applications of fungicides containing Cu, Zn and Mn lead to an accumulation of these metals in the soil, which can interfere with the development of native plants that cohabit vineyards. In this context, the critical levels (CL) of these metals in soil and plants in relation to dry mass production are not sufficiently known, especially in subtropical climates. The aim of this study was to define the CL of Cu, Zn and Mn in the tissue of plants grown between the rows and in the soil, in vineyards in the Pampa biome. To this end, the CL these metals in the plant tissue and soil of the three areas were determined: vineyard 1 (without soil turning after the first planting) (V1), vineyard 2 (soil turned after the first planting) (V2) and native field (NF) (without agricultural crops). To estimate the CL of metals in tissue and soil in relation to dry mass production, estimation models were developed using regression with plateau. Hierarchical Bayesian analysis was used to adjust the regression models. In the tissue, the CL of metals were 75, 77 and 380 mg kg<sup>-1</sup>, respectively. In general, the lowest values of Cu and Zn in the soil and tissues were observed in the NF, as well as the highest dry mass production. The lowest concentration of Mn in the tissue was in the V1 plants. The CL values in the soil were 20, 3.5 and 45 mg dm<sup>-3</sup>, respectively. V1 had the highest levels of Zn and Mn in the soil and the lowest amounts of dry mass produced. Thus, excessive applications of fungicides based on Cu, Zn and Mn not only increase their concentration in the soil and tissue, causing phytotoxicity, but also tend to reduce the richness of native species. By estimating CL values, it is possible to gain a better understanding of fungicide application management, it being a good indicator of soil toxicity and contamination.

### BERRY MORPHOLOGY STUDIES ON FURMINT AND KÖVÉRSZ?L? GRAPE VARIETIES FROM LOESS AND VOLCANIC SOILS

L. VARGA<sup>1</sup>, P. BALLING<sup>1</sup>, Z. KÁLLAI<sup>2</sup>, I. KISS<sup>1</sup>, T. KOVÁCS<sup>1</sup>, P. MOLNÁR<sup>1</sup>, C. OLÁH<sup>1</sup>, A. KNEIP<sup>1</sup>

<sup>2</sup> Tokaj Research Institute for Viticulture and Oenology, HUNGARY

Berry morphology the discipline that analyses in detail the structure, shape, size, colour, skin, seeds and other characteristics of berries. Berry morphology plays an important role in understanding fruit development processes. Tokaj-Hegyalja is one of Hungary's most famous wine-producing regions. The area lies at the northern foot of the Zemplén Hills and is the centre of Tokaj wine production. The vineyards here have exceptional environmental and soil conditions, which give the wines their unique character. The Tokaj hills are known for their unique volcanic and loess soils, rich in minerals and with excellent drainage, which create ideal conditions for growing grapes. These soil characteristics give Tokaj wines, especially Furmint and Kövérsz?l?, their unique characteristics. The Furmint grape variety is the basis of Tokaj wines. The grape variety has a long history in the region and is one of the main ingredients of Tokaj Aszú wines. The Furmint grape is particularly well adapted to the climate and soil of the Tokaj hills. The volcanic soils and favourable climatic conditions give the Furmint grape excellent quality berries, which produce exciting and complex wines. The Kövérsz?l? grape variety also plays an important role in the palette of Tokaj wines. The difference lies in the mineral composition, water balance and temperature regulation of the soil types. The diversity of Tokaj wines is partly due to this terroir, which gives the wines of the region a unique and distinctive character. In 2023, I conducted berry morphology experiments on Furmint and Kövérsz?l? grapes. The sample was taken from loess and volcanic soils. I wanted to find out whether the berries from the different soils develop differently and whether they are affected differently by the *Botrytis cinerea*. In my experiment, 100 berries per variety and soil type were tested. I took berry sections and analysed them using digital image analysis software. I examined berry diameter, skin thickness, seed parameters, berry flesh to seed ratio and spacing.

<sup>2</sup> University of Debrecen, HUNGARY

<sup>3</sup> University of Gothenburg, SWEDEN

<sup>4</sup> Gróf Degenfeld Wine Estate, Tarcfal, HUNGARY

Monoculture of vineyards, excessively applying artificial chemical fertilizers and pesticides will result in extensive soil degradation in terms of acidification, loss of organic content, loss of soil biodiversity, degradation of the physical properties of the soil, loss of water holding capacity, and finally, turning healthy soils into non-soil. Furthermore, use of heavy machines in the vineyard causes soil compaction which inhibits the development of the root system of vines. It is important to realise, that soil is a living substance, an ecosystem where healthy soil biodiversity is a prerequisite for the maintenance biogeochemical cycles, which are the key drivers of ecosystem services provided by soils. Although the introduction and the fast development of precision agriculture has reduced the input of agrochemicals, it did not change the monoculture and did not improve the biodiversity of vineyard ecosystems. Furthermore, from an economic perspective, agrochemicals are expensive, they support a linear economy in agricultural production while important resources, such as cover crops, organic waste, and purified wastewater are not utilized. The solution is a new, complex system based on the potential multifunctionality of agriculture, organic production, complex product and service structure of a recycling, circular economy, where soil conservation and management have a central role. Out-phasing artificial chemical fertilizers and pesticides and establishing a fully recycling system in wine production has several steps in terms of wastewater purification, organic waste management, renewable energy production, cover crops, biological pest management, and developing full product structure based on available ecosystem services. Wastewater purification yields biologically clean wastewater, which is a nutrient solution for irrigation (after appropriate treatment), sewage sludge, which can be co-fermented with organic waste and produce biogas and biosolid, that can be further processed to vermicompost, a high-quality natural fertilizer for soils. Using cover crops such as legumes and herbs will supply soil nitrogen and increase the biodiversity of the vineyard and yield additional crops. In one system, including a complex product structure of the grapevine (fruit, fruit juice, wine, distilled spirits, grapeseed oil, grape skin extract, marc for animal food, marc for medical products, etc.) and services (tourism, consultancy, events) the economic viability will be secured.

### A REGENERATIVE APPROACH TO SOIL HEALTH AND BIODIVERSITY IN VITICULTURE

L. CSIGE <sup>1</sup>, M. TÓTH <sup>5</sup>, Z. SZEKÉR <sup>2,4</sup>, C. OLÁH <sup>2</sup>, S. NÉMETHY <sup>1,2,3</sup>

<sup>1</sup> University of Debrecen, HUNGARY

<sup>2</sup> University of Tokaj, Sárospatak, HUNGARY

<sup>3</sup> University of Gothenburg, SWEDEN

<sup>4</sup> University of Miskolc, HUNGARY

<sup>5</sup> Gróf Degenfeld Wine Estate, Tokaj, HUNGARY

Mainly monocultural vineyards require intensive use of pesticides against fungal diseases (e.g., powdery mildew and grey mould) and insect pests with adverse effects on biodiversity, ecosystem functions and the human health. Growing concerns about the direct and indirect effects of pesticides and synthetic soil conditioners are putting increasing pressure on farmers to reduce their dependence on chemicals and develop sustainable, preferable organic farming systems. Certain control of pests and fungal diseases in vineyards may be achieved by short cutting certain some crops (e.g. inter-row grassing), but this approach affects above and below ground biodiversity and limits the amount of carbon stored in the soil. Thus, a wider variety of useful cover crops such as legumes with nitrogen-fixing symbionts, many herbs and spices can be beneficial, since some of them have even insect repellent properties.

Grape growers need to future-proof their production, not only by relying more on alternative pest and disease management strategies, but also by strategies to capture and store more carbon in the soil. Viticulture research has so far focused primarily on approaches to maximise the quality and quantity of grapes produced, resulting in large-scale industrial agriculture and soil depletion. What we need now is research that will also move the sector forward in terms of regenerative environmental sustainability. The term "regenerative" refers to the reconstruction of depleted agroecosystems. Therefore, designing biologically divers agroecosystems while taking measures to sequester and store more carbon in the soil, will increase soil biodiversity and even contribute to climate resilient agriculture.

The ecological restoration of previously monocultural vineyards using cover crops and forest strips creating new habitats, including windbreaks and biofilters, provides significant production benefits, which support soil health, disease prevention, and environmental sustainability. Furthermore, increasing the biodiversity of vineyards and vineyard soils is likely to enhance the development, diversity, and abundance of arbuscular mycorrhizal fungi (AMFs), which are considered essential for the healthy functioning of terrestrial ecosystems. They facilitate nutrient cycling and the supply of nutrients and water directly to colonized plants and increase tolerance to biotic and abiotic stresses and diseases being hereby an important factor for ecological intensification.

**Keywords:** monoculture, pesticides, soil conditioners, soil carbon sequestration, soil biodiversity, organic farming, cover crops, agroecosystems, regenerative sustainability, climate resilience, arbuscular mycorrhiza, biotic stress, abiotic stress

### COMPARISON OF PIWI AND CONVENTIONAL GRAPE VARIETIES IN THE BALATONBOGLÁR WINE DISTRICT

P. PODMANICZKY, I. KISS

University of Tokaj, Dept. of Viticulture and Enology, H-3950 Sárospatak, HUNGARY

In the European Union, environmental and health protection is an increasingly important requirement. The use of polluting pesticides is becoming more restricted every year. In recent years, the cost of wine grape production has been rising steadily due to the unfavourable economic trends. These challenges are difficult to meet with conventional grape varieties, the best solution is to use disease and pest resistant PIWI grape varieties, which are suitable to produce the same quality of wine with almost identical organoleptic properties as the corresponding conventional varieties. Since the choice of terroir in terms of climate, aspect and soil quality is important regarding wine quality, the Balatonboglár wine district was chosen as experimental site on the southern shore of Lake Balaton, in the Balaton wine region. In 2023, 2 PIWI (Muscaris (Solaris x Muscat Lunell) and O8-3/9 (O1-1-840 (BC5) x Riesling)) varieties were compared with 2 conventional (Muscat Lunell and Riesling) varieties in the Balatonboglár wine district. We expected at least similar or identical chemical characteristics and organoleptic properties in the PIWI and the conventional control varieties. The production area is west facing. The soil-forming rocks are sandy loess, the physical soil type is sandy loam with a medium humus layer thickness and a slightly humic soil. From the surface, carbonate soil with weak alkaline chemistry. Must samples were taken at harvest and the musts were fermented into wine using the same technology under the same fermentation conditions. Must and wine samples were analysed for 44 parameters (e.g., alcohols, sugars, organic acids, amino acids, higher alcohols, polyphenols) using a Bruker Ascend 400 NMR instrument. The wines were also evaluated organoleptically. Our research gave the expected results, since no significant differences were measured between PIWI and control varieties.

**Keywords:** PIWI grape varieties, disease resistance, soil properties and wine quality, chemical characterization of must and wine, sensory evaluation

### 6.05 131572 - Advancing Quantitative Soil Classification: From Soil Profiles to a Dynamic and Comprehensive Classification System

#### A MULTI-LAYER NUMERICAL SOIL CLASSIFICATION SYSTEM FOR AUSTRALIA

A. MCBRATNEY, W. NG

The University of Sydney, Sydney, AUSTRALIA

One of the priority areas for developing pedometrics is the hope of a numerical classification system for soil layers, horizons and profiles for the world. Progress towards this endeavour is underway through the initiation of the Global Numerical Classification System for Soil Layers and Profiles (GNCSSLP). Wadoux and McBratney (submitted) have created a surface layer numerical classification for the world. In this study, we will demonstrate a multi-layer numerical classification system for Australia.

To achieve this, a comprehensive dataset of relevant soil property maps for Australia, including soil texture, pH, organic carbon and its various fractions has been compiled. The k-means clustering algorithm was applied to generate the optimal number of k-means clusters from the one million points sampled from these maps and repeated 100 fold. A plateau in the ratio of between-cluster dispersion to within-cluster dispersion is used as the convergence criterion. The initial centroid clusters were identified from one of the replicates, and the k-means algorithm was iteratively applied across subsequent replicates to refine the centroid clusters. Subsequently, we allocated the soil properties at all locations on the maps to their nearest centroids resulting in a high-resolution numerical soil layer classification for the whole country.

With three depth-layer clustering established, we extended our classification to encompass the top 30 cm of the soil profile. This comprehensive approach marks a critical step towards the development of a unified and objective soil classification system. Our findings pave the way for a standardized global (unsupervised) numerical classification system, offering invaluable insights for soil science and its diverse applications.

<sup>2</sup> Hungarian Soil Science Society, Miskolc

Most national soil classification systems were developed before modern data collection and computer based processing tools were available. The Hungarian Diagnostic Soil Classification System (HDSCS) is based on the experiences of the traditional genetic-based system, the accumulated field and laboratory data and the pedometric evaluation and processing of them. The poster is presenting the elements (diagnostic horizons and properties), the structure and the classification key of the 15 soil types of the HDSCS. Example profiles with pictures, data and major properties will be used to introduce the units, complemented with correlation information with the World reference base for soil resources (WRB, 2015) units.

### 6.06 133437 - Novel approaches to process-based modelling in agricultural soils

#### THE USE OF ABM FOR THE STUDY OF EROSION PROCESSES IN THE AGRICULTURAL LANDSCAPE OF SOUTH MORAVIA

M. BEDNAR, B. SARAPATKA

Palacky University, Olomouc, CZECH REPUBLIC

The paper demonstrates the possibilities of using Agent-Based Modeling (ABM) to model water erosion on highly endangered land in the South Moravia region, one of the most fertile areas in the Czech Republic. Currently, soil erosion calculations in this region rely on the Universal Soil Loss Equation (USLE) methodology. The erosion limits set by USLE, which determine permissible values of combined Cover and Management (CP) factors, restrict the cultivation of erosion-prone crops, such as maize, on vulnerable areas. Moreover, the extensive surface area of individual soil blocks, resulting from post-war collectivization, land consolidation, and the loss of field-breaks and green elements, has contributed to high erosion runoff, making the resulting blocks among the largest in Europe. Efforts are underway to change this situation by dividing large soil blocks into smaller ones.

This division of soil blocks impacts the calculation of erosion according to the USLE methodology, primarily designed for calculating average erosion runoff for a field with one crop. It may not be accurate when multiple crops are present unless the crop change also interrupts the concentrated outflow path. Physically based models can interpret this situation, but they are more demanding in terms of input data and are specific to each sub-area.

In this paper, we demonstrate the potential of using ABM methodology to qualitatively capture the effects of soil block division (horizontal, vertical, strip cropping). This approach provides general information about the relevance of designed measures in relation to erosion hazards. The proposed mechanism offers retrospective guidance for possible modifications of parameters (P) in commonly used empirical models of the (R)USLE type.

Addressing these issues is a focal point of projects coordinated by the Czech Technological Agency (Center for Landscape and Biodiversity – SS02030018 and Strip Cropping as an Adaptation Measure for Optimizing Landscape Water Management – SS06010290), aligning with EU and Czech Republic strategies.

#### DIGITAL MAPPING OF RELEVANT SOIL CLASSIFICATION UNITS IN HUNGARY TO SUPPORT PRECISION AGRICULTURE

S. CSENKI<sup>1</sup>, E. DOBOS<sup>1</sup>, V. LÁNG<sup>2</sup>, I. CZAKÓ<sup>3</sup>

<sup>1</sup> University of Miskolc, Miskolc, HUNGARY

<sup>2</sup> Discovery Center NLtd., Gödöllo, HUNGARY

<sup>3</sup> Karotin Ltd., Szeged, HUNGARY

Most of the data collected for precision agriculture in Hungary comes from the top soil and does not take into account the deeper layers. Although for precision agriculture, the classification units can lead to a deeper understanding of the main drivers that limit yields. The aim of our study is to identify the major WRB and proposed Hungarian Classification (HSCS) diagnostic units applicable in a precision agricultural system under Hungarian soil and climatic conditions, and how they relate to the yield potential of a selected fields compared to other methods commonly used in precision agriculture, such as contact and non contact soil scanning methods, vegetation biomass mapping, different surface sampling strategies. The results show that the classification units strongly correlate with yield potential under climatic and landscape conditions of our study area and can be used to plan precision agriculture.

<sup>2</sup> Department of Biology, University of Naples Federico II, Naples, ITALY

Since of the impact of berry composition on juice, must, and finally on wine composition and quality, the grapevine mineral element concentration is of concern not only for scientists but for oenologists and winemakers too. Several of research focused on grape composition rather than on wine for understanding on transfer/accumulation processes in the soil-vine system avoiding the anthropogenic source related to winemaking practises. Evaluations on the relationship between total soil element content and plant tissue composition highlighted a disconnect governing their accumulation. However, poorly investigated have been the soil-grape transfer processes under surveyed soil spatial variability contexts and application of selective extractions allowing the measurement of the soil bioavailable element (BE) content that is more appropriate for soil-plant uptake studies.

This research focused on the soil-vine system, analysing soils and Aglianico grapes from the wine production area of the Taurasi Protected Designation of Origin-PDO (South Italy). Three vineyards were selected in similar pedoclimatic environments, preliminary surveyed by electromagnetic induction (EMI) proximal sensor for soil variability identification and accordingly sampled in four points for each vineyard. Soils were sampled in triplicate while grapes were collected at harvesting from 6 plants surrounding the soil sampling points. Portable X-ray fluorescence (pXRF) spectrometry and single extraction with ammonium acetate 1M have been applied to measure the total (TE) and the BE content from soils, respectively, while the element distribution pattern of grape (skin, seed and pulp) has been determined after grape mineralization and analysis by ICP-OES spectrometer.

The multivariate analysis (PCA) based on the soil TE and BE content and that on grapes composition revealed quite homogeneous distributions among vineyards. Bioconcentration factors (BF), calculated as log transformed ratio of grape berry concentrations divided by the soil BE content, allowed to identify soil to grape berry transfer for Cu, Fe, Zn, Na, B and S in skin, seed and pulp, while accumulation was not found for Mn, Li, Sr and Ca.

### 6.06 133437 - Novel approaches to process-based modelling in agricultural soils

#### A TWO-STEP MODEL TO PREDICT TEMPORAL VARIABILITY OF SOIL HYDRAULIC PROPERTIES IN AN AGRICULTURAL FIELD WITH LOAMY SOIL

S. KUMAR, R. OJHA

Indian Institute of Technology Kanpur, Kanpur, INDIA

Temporal variability in soil hydraulic properties (SHPs) in agricultural fields has been reported by several studies, but it is rarely considered in subsurface modelling. The experimental measurements for determining SHPs at multiple timescales are expensive and time-consuming. Further, obtaining parameters for existing numerical and analytical models for describing temporal variation in SHPs is difficult. Alternatively, scaling can be used to describe spatial-temporal variability of SHPs and relate them to subsurface media properties. This study aims to develop a simplified model for describing temporal variation in SHPs which relies on only a few field measurements for a loamy soil. For this, temporally variable reference soil water characteristic curves (SWRCs) and hydraulic conductivity curves (HCCs) were synthetically generated for various parameter combinations. The temporally varying SWRCs and HCCs were scaled by functional normalization approach to obtain time varying reference curves and scale factors. Using regression analysis, a two-step equation was developed to relate time-varying scale factors and the initial SHPs. The developed reference curves and equations were validated by 5-fold cross validation method. During cross validation the average percentage error in predicted van Genuchten parameters and  $K_{sat}$  were mostly below 10 %. The proposed method holds promise for describing temporal variation in SHPs using only the initial SHPs.

#### IMPACT OF DEM RESOLUTION ON HYDROLOGICAL RESPONSE SIMULATION USING NASH GIUH MODEL

E. ELDEEB <sup>1</sup>, A. COPPOLA <sup>2</sup>, A.H. RABIA <sup>3</sup>

<sup>1</sup> CIHEAM Mediterranean Agronomic Institute of Bari, Land and Water Division, Bari, ITALY

<sup>2</sup> University of Cagliari, Department of Chemical and Geological Sciences, Cagliari, ITALY

<sup>3</sup> North Dakota State University, Department of Agricultural and Biosystems Engineering, Fargo, ND, USA

Geomorphological instantaneous unit hydrograph (GIUH) based on Nash model is considered an effective approach for modelling the hydrological process of ungauged basins in arid regions. Model parameters represent the geomorphologic details of the basin and the climatological characteristics. Geomorphologic parameters are extracted from the digital elevation model (DEM). The model output is influenced by the DEM resolutions. This study developed a modelling methodology for evaluating the impact of DEM resolutions, specifically at 20 and 30 meters, on the computed direct surface runoff hydrograph (DSRH) based on Nash GIUH model. A computer program was developed to systematically derive computed DSRH. Computed DSRH was compared with observed DSRH derived from measurements at the outlet of Agarma sub-catchment of the Wadi Kharouba in the North Western Coastal Region of Egypt for two rainfall events observed from Oct 2015 to Mar 2016. Geomorphologic information was derived from DEM of the basin and QGIS was used for data processing. The results showed that for both rainfall events, the 20 m resolution DEM consistently outperforms the 30 m resolution DEM in terms of efficiency (EFF). In the rainfall event on 16th November 2015, the 20 m resolution DEM exhibits lower errors across various metrics, including AEV, PEP, RMSE, and AAE, indicating better accuracy in simulating hydrological processes. Similar trends were observed in the rainfall event on 30th December 2015, with the 20 m resolution DEM showing higher efficiency and lower errors compared to the 30 m resolution DEM. The percentage errors in peak flow (PEP) and time to peak (PETP) are generally higher for both resolutions in the December event, suggesting increased complexity or challenges in accurately predicting hydrological responses during this event. In conclusion, the results consistently indicate that the 20 m resolution DEM provides more accurate and efficient simulations of the hydrological response compared to the 30 m resolution DEM for both rainfall events.

### WEATHERING MECHANISMS AND SOIL FORMATION IN A MORAINIC LANDSCAPE OF THE THREE LAKES REGION (SWITZERLAND)

<sup>1</sup> University of Zürich - Department of Geography, Zürich, SWITZERLAND

<sup>2</sup> University of Calabria - Department of Geography, Arcavacata, ITALY

<sup>3</sup> Bern University of Applied Sciences - School of Agricultural, Forest and Food Sciences, Bern, SWITZERLAND

This study aims to better understand the evolution of soil on morainic material in the temperate regions. During the last glaciations, the Three Lakes region (Switzerland) was repeatedly covered by ice, resulting in the deposition of morainic material. Quaternary glaciations strongly reworked Molasse sediments and left a mantle of mixed autochthonous and allochthonous superficial deposits (regolith) covering the landscape. While the allochtony of the morainic material in the Swiss Plateau is not questioned, the trajectories of soil evolution are underexplored. Exploring these trajectories will provide precious information on the rate and directions of soil and landscape evolution.

10 soil profiles from 5 main sites were analysed. In addition to classical soil analysis, also the micromorphology was studied together with a quantitative assessment of macropores using computational tomography. As soil registers directional changes, micromorphological analyses of soil features are a powerful means to decipher soil evolution. The micromorphology helped us understand whether the different horizons were formed in situ or elsewhere and then transported. Additionally, using elemental analysis, we calculated various weathering indices to confirm the observed features.

The investigated soils showed a distinct accumulation of clay and silt in the B horizon. The clay accumulation is a relic feature of eluviation-illuviation processes. Indeed, hilltop sites had more clay coatings than the toeslope sites, where clays are present only in the transported form (papules). Moreover, beyond quantity, the composition of the clays also varied as a function of the topography. We observed clear brownish clay coatings in the hilltop profile, in comparison to the toeslope profile where clay accumulation was more yellow and coarser (additions of silt).

**EFFECT OF TOPOGRAPHIC VARIATIONS AND TILLAGE METHODS ON GULLY EROSION IN THE BLACK SOIL REGION OF NORTHEAST CHINA**

J. TANG<sup>1</sup>, G. LIU<sup>1</sup>, Y. XIE<sup>2</sup>

<sup>1</sup> Faculty of Geographical Science, Beijing Normal University, Beijing, CHINA

<sup>2</sup> Faculty of Arts and Sciences, Beijing Normal University at Zhuhai, Zhuhai, CHINA

Gully erosion is considered to be a severe land degradation process around the world. The combined effects of tillage methods and topographic variation on gully erosion are poorly understood. The unequal probability area sampling method was used to investigate gullies in three farmland, geomorphic areas in the black soil region of northeastern China: low mountains and hills, tableland, and rolling hill areas. Cross-sectional measurements were used to obtain estimates of volumetric soil loss from the gullies. Digital contour maps and remote sensing images were used to obtain the topography and row direction data direction, and the Redundancy analysis (RDA) was used to analyze the contribution of different influencing factors. The results showed that tableland area had the greatest volumetric soil loss and was the most prone to develop gully erosion, followed by the low mountains and hills, and finally the rolling hill areas. Topography was the dominant control on gully erosion and volumetric soil loss and length density increased first and then decreased as a function of increase of slope gradient. Farmland with slope gradient between 15° and 20° had the most serious gully erosion. Compared to other geomorphic areas, low mountains and hills had the most gully types and the greatest variability of morphology. Surface areas and volumes were related to gully type. Different tillage methods have affected the frequency of gully occurrence. Cross-slope tillage areas were more prone to develop gully erosion than contoured tillage and up and down slope tillage areas, especially for farmlands with slope of 5 to 10°. The results suggest that gully erosion could be reduced if up and down slope tillage was used for slope gradients less than 15° and contoured tillage was used for slope gradient greater than 15°. This study demonstrates the combined effect of topographic variations and tillage methods on gully erosion, and highlights the importance of considering different tillage methods under different geographical conditions to control gully erosion.

<sup>4</sup> Advanced Institute of Natural Sciences, Beijing Normal University, Zhuhai, CHINA

Topography is an important factor affecting soil erosion. It is measured by the combined slope length and slope steepness (LS-factor) in erosion estimation models (such as the Revised Universal Soil Loss Equation (RUSLE), and Chinese Soil Loss Equation (CSLE)). Shuttle Radar Topography Mission (SRTM), a high-resolution elevation data on a global scale, has been widely used to assess global soil erosion. However, global high-resolution LS-factor datasets based on SRTM have rarely been published. Challenges arise when attempting to extract the LS-factor on a global scale. Furthermore, existing LS-factor estimation methods necessitate projecting data from a spherical trapezoidal grid to a planar rectangle, resulting in grid size errors and high time complexity. Here, we present a global 1-arcsec resolution LS-factor dataset (DS-LS-GS1) with an improved method for estimating the LS-factor without projection conversion (LS-WPC), and we integrate it into a software tool (LS-TOOL). Validation of the Himmelblau–Orlandini mathematical surface shows that errors are less than 1%. We assess the LS-WPC method on 20 regions encompassing 5 landform types, and R<sup>2</sup> of LS-factor are 0.82, 0.82, 0.83, 0.83, and 0.84. Moreover, the computational efficiency can be enhanced by up to 25.52%. DS-LS-GS1 can be used as high-quality input data for global soil erosion assessment and can be available at <https://doi.org/10.11888/Terre.tpd.300613>.

### OBLIQUE SLOPE RIDGE-FURROW TILLAGE FACTOR FOR REGIONAL SOIL EROSION MAPPING

L. DONG<sup>1</sup>, B. LIU<sup>2,3</sup>

<sup>1</sup> Faculty of Geographical Science, Beijing Normal University, Beijing, CHINA

<sup>2</sup> Advanced Institute of Natural Sciences, State Key Lab of ESPRE, Beijing Normal University at Zhuhai, Zhuhai, Guangdong, CHINA

<sup>3</sup> State Key Lab of SEDF on the Loess Plateau, Institute of Soil and Water Conservation, Northwest A&F University, Yangling, Shaanxi, CHINA

Ridge-furrow tillage is a widespread agricultural practice. In hilly regions, both cross-slope (contour) and up-down slope ridge-furrow tillage are employed, but oblique slope ridge-furrow tillage is more common. This method refers to a tillage direction that is neither parallel nor perpendicular to the contour lines but forms an angle with them. Previous evaluations of soil erosion generally did not take this into account. The purpose of this study is to analyze the effect of oblique slope ridge-furrow tillage on soil erosion and construct a universal method for its calculation. This method can serve as a general form capable of replacing the calculation of contour and up-down slope tillage (specific cases). Taking Nenjiang City (15211.43km<sup>2</sup>) as an example, 39 sample units were deployed based on the sampling approach. Combining remote sensing image interpretation and field investigation, we propose the process of calculating the angle of the ridge-furrow direction (the angle between the ridge-furrow direction and the contour line), followed by the computation of a correction coefficient for the ridge-furrow direction at relative contour tillage, and then deriving the factor of oblique slope ridge-furrow tillage. The results showed that high-precision interpretation of ridge-furrow direction in the region can be achieved based on remote sensing images. The average variation in the angle of ridge-furrow direction within a single field is 40.2°. Oblique slope ridge-furrow tillage is predominant, with an average factor value of 0.81. This factor, previously overlooked, leads to a 30.5% overestimation of soil erosion. Consequently, soil erosion assessments should not be confined to contour tillage alone, but should also incorporate oblique slope tillage. In addition, practical evaluations of their benefits at the field scale can be difficult, but it can be effectively conducted using a grid as the unit of analysis. The proposed method can comprehensively express the soil conservation benefits associated with ridge-furrow direction, improve the accuracy of regional soil erosion assessment, and better serve soil conservation planning.

Under a climate change scenarios water erosion damages are becoming more important. However, evaluation of water erosion risk is usually model-based and complex and not appealing to end users. Paradoxically, key information to predict erosion risk can only be properly identified at farm scale with help from practitioners.

There is scope for tools allowing practitioners appraisal of water erosion risk. One successful example is Millgroom et al. (2007), based on a simplified version of RUSLE (Renard et al., 1997) to assess water erosion risk at farm scale for organic olive growers in S. Spain. Its uses four steps: 1) to divide the farm into homogenous areas; 2) to evaluate the general erosion risk by area taking into consideration, topography, crop typology and management; 3) to conduct an on-farm check for the visual symptoms of soil erosion; 4) to combine the general erosion risk (Appraisal 1) and the on-farm check (Appraisal 2) to assess the overall erosion risk. This tool proved successful among practitioners, but in its original form it is confined to a specific niche.

We present the current status of an, in progress, tool for appraising water erosion risk in valid in multiple environments and woody crops, developed in cooperation among European and Chinese teams and stakeholders. It combines a dual approach combining erosion risk estimation in field check of erosion symptoms. It is aimed for hybrid format, available either in a paper form (which remains the most operational one in many field conditions) or web-based. With this we aim to deliver:

1- a standardize tool valid across multiple environments and woody crops to evaluate water erosion risk.

2- an educational tool on prevention of water erosion.

### RECONSTRUCTION OF SOIL DENUDATION EVENTS AND THE DISAPPEARANCE OF LUVISOLS IN THE LOESS LANDSCAPE OF TRZEBNICA HILLS (SW, POLAND)

A. LOBA<sup>1</sup>, J. ZHANG<sup>2</sup>, J. WAROSZEWSKI<sup>3</sup>

<sup>1</sup> NICOLAUS COPERNICUS UNIVERSITY IN TORUN, TORUN, POLAND

<sup>2</sup> LEIBNIZ INSTITUTE FOR APPLIED GEOPHYSICS, HANNOVER, GERMANY

<sup>3</sup> WROCLAW UNIVERSITY OF ENVIRONMENTAL AND LIFE SCIENCES, WROCLAW, POLAND

Loess landscapes are very susceptible to erosion processes, which affects the stability, productivity, and transformation of soils. The Trzebnica Hills located in SW Poland are one of such areas. Using optically stimulated luminescence (OSL) dating a complete record of denudation processes in SW Poland was reconstructed. The first phase of sediment redeposition on the slopes occurred about 9.1 ka ago. Subsequent ones were attributed to the Neolithic ( $6.4 \pm 0.3$  ka), early Bronze Age ( $3.8 \pm 0.2$  ka), early and late Middle Ages ( $1.5 \pm 0.1$  ka and  $0.7 \pm 0.03$  ka) and early Modern Period ( $0.4 \pm 0.02$  ka).

As a result of the erosion-deposition processes, the soil cover in the studied area had been strongly reshaped. The predominant Luvisols had experienced progressive erosion processes that led first to a significant shallowing of the eluvial and argic horizons (truncated Luvisols) and, after some time, to their complete removal. Further thinning of the loess mantles had caused that older sediments without pedogenic alternations like glacial tills and glaciofluvial substrates were exhumated. Therefore, soil transformation was towards reference group of Regosols. Similarly, Regosols occurred in toeslopes where freshly eroded material had been deposited, and where diagnostic horizons had not yet developed.

Based on medium-term soil erosion rates, it is calculated that the soil class in studied area may have significantly changed within 80 – 200 years, if not sooner due to progressive climate change. It is alarming and very important because erosion and soil degradation are issues specifically highlighted in the 2001 European Parliament's resolution on soil protection.

This research was financed by the National Science Center (Poland) project number 2018/29/B/ST10/01282 (Opus 15).

**IMPLEMENTATION OF THE WIND EROSION EQUATION INTO GIS TECHNOLOGY FOR MODELLING POTENTIAL SOIL LOSS DUE TO WIND EROSION ON AGRICULTURAL SOIL**

P. ZALESAK, J. KOZLOVSKY DUFKOVA, T. MASICEK

Mendel University in Brno - Department of Applied and Landscape Ecology, BRNO, CZECH REPUBLIC

Wind erosion is a fundamental natural phenomenon that becomes a serious problem due to human activity and can eventually lead to desertification. This study is focused on determining the potential soil loss caused by wind erosion in agricultural fields. Additionally, it explores the implementation of biotechnical measures to control wind erosion in a specific model area located in South Moravia (Czech Republic, EU), which is affected by wind erosion. One of the method involves the use of equations and models, which, when implemented with GIS technology, become powerful tools due to their speed, visualization capabilities, and the ability to use freely accessible data. Many of these models are based on equations, but they differ in terms of regional characteristics or variations in their demands for input data. One of the most commonly used equation is the Wind Erosion Equation (WEQ), which considers soil erodibility, soil ridge roughness, climate, unsheltered length, and vegetative cover. In this study, the WEQ was implemented in ESRI ArcGIS Pro 3.0 using raster analysis techniques to determine potential soil loss due to wind. The use of the WEQ in this study represents a versatile method that can be applied in different scenarios and for various purposes. For modelling wind erosion in this study, freely available hydrometeorological data from the Czech Hydrometeorological Institute were used to determine climate factors. The unsheltered length was determined through height analysis using data from the Digital Elevation Model (DEM) and Digital Surface Model (DSM), while soil erodibility was based on laboratory analyses of the soil in the study area. Vegetation and soil ridge roughness were ignored in determining potential soil loss due to wind erosion. This study found out a reduction in potential soil loss by wind in agricultural fields by more than 70% with the optimal use of biotechnical measures for wind erosion control.

### INITIATING THE PREDICT-ER: A NEW MULTIDISCIPLINARY FRAMEWORK FOR THE DEVELOPMENT OF AN EROSION PREDICTION TOOL

S. DRAGOVIĆ<sup>1</sup>, I. SMICIKLAS<sup>1</sup>, M. DJORDJEVIĆ<sup>2</sup>, M. DJOKIĆ<sup>2</sup>, M. GOCIĆ<sup>2</sup>, M. MANIĆ<sup>3</sup>, A. CUPIĆ<sup>1</sup>, D. TOPALOVIĆ<sup>1</sup>, M. JOVIĆ<sup>1</sup>, R. DRAGOVIĆ<sup>2</sup>, B. GAJIĆ<sup>4</sup>

<sup>1</sup> VINCA Institute of Nuclear Sciences, National Institute of the Republic of Serbia, University of Belgrade, Belgrade, SERBIA

<sup>2</sup> University of Nis, Faculty of Sciences and Mathematics, Department of Geography, Nis, SERBIA

<sup>3</sup> University of Belgrade, Faculty of Geography, Belgrade, SERBIA

<sup>4</sup> University of Belgrade, Faculty of Agriculture, Belgrade, SERBIA

Significant progress in studying and subsequent modeling of erosion processes resulted in the development of many empirical, semi-empirical, and physically-based models, ranging from simplistic equations to complex models considering multiple interacting factors. However, the ease of their use with remotely sensed data and geostatistics increased the number of models and tools that rely on globally available data and lack field activities and validation. These drawbacks limit their applicability in identifying priority areas and site-specific measures for effective soil management. Here, a new concept for developing an erosion prediction tool (Predict-Er) is presented, and the field/laboratory analyses as input for tool development are discussed. The Predict-Er brings a novel approach that combines nuclear, analytical, statistical, and remote sensing techniques to produce high-resolution field data, which will be modeled and integrated within a multilayer web GIS Predict-Er tool to enable predicting changes in soil erosion rates and sediment dynamics over various management scenarios. It aims to predict soil erosion rates and sediment yield by simulating the effects of land use/cover changes, precipitation, land management, and conservation measures. Sediment fingerprinting, integrated with other methods, is envisaged to furnish data for directing interventions in sediment management. Thus, the Predict-Er Tool facilitates decision-making processes for stakeholders aiming to implement informed conservation measures to mitigate the dual impacts of on-site and off-site consequences of soil erosion. The tool developed on representative study catchment in Serbia will be validated in Spain's catchment of different physiographic and geological characteristics and then thoroughly and continuously tested in other catchments. The Predict-Er approach enhances understanding of the complex interactions among the soil erosion drivers. It contributes to achieving sustainable development objectives, particularly aligned with the United Nations Sustainable Development Goal (SDG) targets related to responsible land use and environmental conservation.

### SATELLITE-BASED SOIL SALINITY PREDICTION USING MACHINE LEARNING IN SOUTHERN TAIWAN

C. SYU <sup>1</sup>, N.T. SON <sup>2</sup>, Y.T. ZHANG <sup>1</sup>, C.F. CHEN <sup>2</sup>

<sup>1</sup> Division of Agricultural Chemistry, Taiwan Agricultural Research Institute, TAICHUNG, TAIWAN

<sup>2</sup> Center for Space and Remote Sensing Research, National Central University, TAICHUNG, TAIWAN

Soil salinity is a widespread environmental concern, which negatively affects plant growth, soil microbiological processes, crop yields, and the quantity of land utilized for agriculture. Impacts of climate change, including sea-level rise and prolonged drought, are predicted to exacerbate this problem and possibly spread it to presently unaffected regions in the near future, impeding agricultural sustainability. Increasing salinization poses real challenges for food security and the world's food supply system. This is also a phenomenon in Taiwan, where soil salinity is widely recognized as a primary cause of land degradation, and has a significant impact on agricultural productivity. Thus, information on soil salinity from spatiotemporal perspectives is crucial for policymakers to develop effective crop management and agricultural planning strategies. The objective of this study is to develop random forest-based models for soil salinity prediction in both space and time using long-historical in-situ observations (electrical conductivity of topsoils) and archives of Landsat satellite imageries and digital elevation model (DEM) acquired during the dry season (November to April). Specifically, the data from 2014 to 2017 were used for establishing models, leaving the 2018 data for model validation. The comparison results between predicted soil salinity results and field observations showed a good correlation between these two datasets with a correlation coefficient of 0.6. This study ultimately led to the potential application of remotely sensed data for predicting soil salinity with machine learning techniques in southern Taiwan. Such methods, providing reliable quantitative information on regional soil salinity, could be transferable to other regions worldwide for soil salinity monitoring.

### INFLUENCE OF SOIL EROSION CONTROL AGRO-TECHNOLOGIES UNDER WHEAT AND MAIZE ROTATION ON SUBSOIL COMPACTION OF MODERATELY ERODED EPICALCIC CHERNOZEM

V. KOLCHAKOV<sup>1</sup>, G. KUNCHEVA<sup>1</sup>, M. KERCHEVA<sup>1</sup>, T. PAPARKOVA<sup>1</sup>, K. DONEVA<sup>1</sup>, G. GYNCEV<sup>2</sup>, E. ENCHEV<sup>3</sup>

<sup>1</sup> ISSAPP N.Poushkarov, SOFIA, BULGARIA

<sup>2</sup> IASS Obratsov Chiflik, Ruse, BULGARIA

<sup>3</sup> University of Ruse, Ruse, BULGARIA

The main limiting factors for the fertility of arable Epicalcic Chernozems on sloped terrains in North Bulgaria are soil water erosion, subsoil compaction and crust formation due to soil structure deterioration. The effects of three agro-technologies were investigated on adjacent plots with cultivation of winter wheat and maize in rotation on moderately eroded silt loam Epicalcic Chernozem in Trastenik, Ruse district. The studied variants were: up-and-down slope traditional tillage (T0), contour traditional tillage (T1) and crop specific erosion control contour tillage (T2), which included minimum tillage, direct sowing and use of cover crop after wheat harvest, incorporated in the soil as green manure before maize sowing. The aim of the current study was to evaluate the influence of the applied agro-technologies on the subsoil compaction during the whole experiment. The soil sampling was performed in April and October each year. The soil compaction was assessed by data for bulk density (Db), total porosity (Pt) and soil aeration capacity (AC) while deterioration of soil structure was assessed by water stability of soil aggregates. All studied parameters exhibited seasonal variation due to the influence of the applied tillage, crop development, and soil moisture. Db in the upper 0-5 cm layer did not differ among the variants and was  $1.31 \pm 0.1$  g cm<sup>-3</sup> in average for the whole period. The subsoil (15-20 cm) compaction was significantly higher (by 6%) in T0 ( $1.57 \pm 0.08$  g cm<sup>-3</sup>) than in T1 and T2 ( $1.48 \pm 0.11$  g cm<sup>-3</sup>). Correspondingly the opposite tendency was observed in Pt and AC. Limiting aeration conditions (AC < 10% vol.) in subsoil occurred in 92% of the cases, while in T1 and T2 these were 64% and 57%, correspondingly. The compaction in T0 reached 40 cm depth while in T1 and T2 it was manifested till 20-25 cm depth.

**WIDESPREAD SHALLOW LANDSLIDES OCCURRENCE IN THE AFTERMATH OF THE MAY 2023 EMILIA ROMAGNA (ITALY) RAINSTORMS: A RAPID MAPPING APPROACH BASED ON SENTINEL-2 IMAGES**

D. CARDONE, D. NOTTI, M. CIGNETTI, D. GODONE, D. GIORDAN

National Research Council of Italy, Research Institute for Geo-Hydrological Protection (CNR IRPI), Turin, ITALY

Rainfall, earthquake or fast snowmelt can trigger shallow landslides that significantly affect vast areas. Their sudden occurrence poses a substantial hazard, causing damage to population and infrastructures as well as economic losses. Nowadays, the accessibility to spaceborne optical sensors with medium resolution images, available immediately and free of charge, provides opportunities for a prompt mapping of shallow landslides resulting from extreme events. This study introduces a semi-automatic methodology to rapidly detect potential landslides based on the Normalized Difference Vegetation Index variation (NDVIvar) between the pre- and post- event Sentinel-2 images. The methodology consists of a GIS-based user-friendly approach that utilizes the NDVIvar coupled with geomorphological filters. During an emergency, the urgent efforts for mapping bring some limitations, such as the unavoidable use of partially cloud-covered images. A cloud filtering script developed in Google Earth Engine was also integrated to minimise the possible false positives. This innovative procedure was applied to the emergency context of the May 2023 extreme rainfalls that affected the Emilia Romagna Region. Despite the partial cloud coverage (8%), in only 5 days after acquiring Sentinel-2 post-event imagery, we generated a reliable and ready-to-use map encompassing an extensive area of approximately 4000 km<sup>2</sup>. The density of the potential landslides is correlated with the rainfall distribution, revealing that the most affected areas showed a density of approximately 50 landslides/km<sup>2</sup>. In an emergency stage, the limited availability of high-resolution images limited the validation of the obtained results. Despite the limited time frame, early data from web-channels, online newspapers, and a post-event field survey revealed partial positive feedback, showing a great match between the potential landslides identified and the ground truth. The results show that the proposed method is an efficient and prompt tool for emergency operations, allowing the rapid recognition and mapping of the ground effects distribution and identification of the most affected areas, representing a practical help to plan risk management activities and emergency priorities.

Soil erosion processes have a major impact on the fate of soil organic carbon (SOC) and on CO<sub>2</sub> emissions to the atmosphere. There is intense debate in the scientific community on the overall impact of erosion on soil carbon storage, as two antagonistic mechanisms are implicated: i) the mobilization and lateral transport of organic carbon, potentially responsible for organic carbon destocking, and ii) the burial of organic carbon in deposition zones, potentially responsible for organic carbon storage. This work aimed to analyze the impact of water erosion processes on the redistribution and evolution of organic carbon biodegradability in a cultivated catchment in a Mediterranean context (Kamech, Cap Bon-OMERE, 2.63 km<sup>2</sup>). In this work, we report and discuss the SOC content and biodegradability measured on i) horizons from 11 soil profiles and additional topsoil samples to represent the diversity of soil types present in the catchment, ii) suspended sediments sampled during sixteen floods at three points in the hydrographic network, according to a nesting of scales, iii) several cores taken from sediments trapped in the hillslope reservoir located at the catchment outlet. The results highlighted the low impact of water erosion processes on organic carbon levels, both a low enrichment rate during the selectivity process and negligible transport-induced degradation due to the short distances and transfer times between sources and outlet. The analysis of SOC biodegradability along the source-transport-deposit continuum showed a significant increase of SOC biodegradability in sediments trapped in the reservoir, which could be explained by the production of highly biodegradable lacustrine organic carbon.

**EFFECTS OF THE 2021 SIERRA BERMEJA FIRE ON THE SOIL (SOUTHERN SPAIN)**

M.J. PERALES VALLEJO, P. HUESO GONZALEZ, J.D. RUIZ SINOGA

University of Malaga; Institute of Habitat, Territory and Digitalisation, MALAGA, ESPAÑA

Since the Pliocene, Mediterranean ecosystems have been susceptible to forest fires and have been evolving with the incessant activity of this natural ecological factor. Thus, the aim of this work is to evaluate the effects produced on soils by the forest fire in Sierra Bermeja (Malaga province), in order to demonstrate how the regeneration and recovery of this environment, key in the management of its territory, is being carried out. The fire affected a serpentine environment where one of the most important fires of the last decades in the province took place, with 8,401 hectares burned. For this purpose, applied spatial remote sensing techniques, field and laboratory work, and an exhaustive search for statistical information related to the main eco-geomorphological characteristics of the burned area have been used. The results show that approximately 57.6% of Sierra Bermeja was affected by this fire, with moderate-high and high degrees of severity in most of the burned area. It should also be noted that the fire has caused significant changes in certain edaphological properties of the soils sampled. In addition, a number of areas with serious soil erosion problems have been identified.

Healthy soil is essential for agriculture and ecosystem functioning. Changes in soil quality have an impact on the delivery of critical ecosystem services such as food production, water supply, and regulation. Soil erosion is notoriously ephemeral because it is dependent on the nexus of vulnerable soil, weather, and antecedent moisture levels; particularly the occurrence of climate extremes, such as big strong rainfall episodes or droughts with wind. When the right mix of events occurs, positive feedbacks can lead to erosion striking with disastrous environmental and socio-economic consequences. A situation that makes it important to better identify locations where multiple concurrent soil erosion processes may occur.

In this presentation we discuss (i) the geography of soil loss by water, wind, tillage, and crop harvesting erosion; (ii) their possible co-occurrence at EU (Borrelli et al., 2023a) and globally scale (Borrelli et al., 2023b); and (iii) how to better integrate research on soil erosion to improve modeling performances and to support decision-makers in both ex-ante and ex-post policy evaluation.

Soil water erosion is an inherent process in natural ecosystems, but human activities can dramatically increase this processes, causing several environmental and socio-economic issues. Several models have been developed to estimate soil loss due to erosion. One of the most widely used is the revised universal soil loss equation (RUSLE), an empirical model originally developed in US for agricultural soils and now applied worldwide. However, the implementation of Geographic Information Systems (GIS) and remote sensing (RS) tools has made it possible to apply RUSLE calculations to large areas with increasingly high spatio-temporal resolution. Brazil, the largest country in South America and the 5th in the world, is a global agricultural producer for several commodities exported worldwide. The northeastern and southeastern macro-regions were originally covered by different biomes such as tropical forests, savannas, and semi-arid shrublands. Over the past, these regions have undergone several land-use changes and urbanization processes. The aim of this research is to build an empirical RUSLE model for these regions, using open-source RS and GIS data. RUSLE consists of five multiplicative factors. The (R) factor was obtained from the modified Fournier index. The soil erodibility (K) factor was taken directly from the Brazilian map of soil erodibility. Remote sensing data were used to calculate slope length/steepness (LS) and the land cover (C) factors. The LS factor was obtained from the digital elevation model using the GTOPO30 program, while a 10-year record of NDVI available from MODIS data was the source for estimating the C-factor. According to the literature, the (P) factor was set to 1 due to its unpredictability over natural ecosystems and anthropized landscapes. The RUSLE model calculated from GIS and RS data will be useful for decision-making processes in soil management, land planning and environmental conservation contexts of a large region with diverse biomes such as the Brazil's Northeast and Southeast macro-regions.

**MODELING DYNAMICS OF SOIL EROSION BY WATER DUE TO CLIMATE AND SOIL ORGANIC MATTER CHANGES (1980 - 2020) IN THE SOUTHEAST OF THE EAST EUROPEAN PLAIN**

N. KRIUCHKOV<sup>1</sup>, O. MAKAROV<sup>1</sup>

<sup>1</sup> Shenzhen MSU-BIT University - Department of Biology, Shenzhen, CHINA

<sup>2</sup> Lomonosov Moscow State University - Faculty of Soil Science, Moscow, RUSSIA

This research aims to evaluate the dynamics of soil loss through soil erosion by water in agricultural lands in steppe areas using a modification of the RUSLE2 model from the 1980s to the 2010s. The calculation was performed using a raster model of data that included a model of the slope angle, slope length, soil erodibility, rainfall and snowmelt erosivity factors, types of land use, and cover management factor. All data were taken from open sources. The average soil erosion in the territory studied amounted to 1.48 t ha year in the 1980s and 1.72 t ha year in the 2010s. The discrepancy with other studies was 12% for the level of the 1980s and 2–7% for the level of the 2010s. The main factor leading to an increase in soil loss was soil erodibility due to the loss of soil organic matter, which affected about 52% of the studied lands. The increase in the amount of soil loss occurred against a background of compensating processes: a reduction in precipitation and climate change (getting drier), as well as the overgrowth of agricultural lands with natural steppe vegetation. The modified model RUSLE2 has shown good results correlated with other studies for the research area.

**NEW APPROACHES TO ADDRESSING EROSION CONTROL IN AGRICULTURAL PRACTICE**

J. PODHRAZSKA, M. POCHOP, J. KUCERA, P. KARASEK, J. KONECNA

Research Institute for Soil and Water Conservation, Praha, CZECH REPUBLIC

In the conditions of Central Europe, the soil is threatened mainly by water and wind erosion, compaction, acidification, contamination, loss of organic matter and reduction of its quality and its occupation. According to current findings, water erosion is the most extensive cause of soil degradation worldwide. In the Czech Republic, more than 60 % of agricultural land is potentially threatened by water erosion and more than 30 % by wind erosion. This is linked both to large blocks of land and intensification of agriculture and to changes in cropping preferences and the decline in livestock production. There are also significant changes in rainfall distribution, probably linked to ongoing climate change, leading to changes in the duration, frequency and magnitude of rainfall. New legislation and changes in GAEC conditions reflect the need for increased soil erosion protection. The assessment of erosion vulnerability is standardly carried out using the USLE method - the Universal Soil Loss Equation for Erosion (Wishmeier and Smith, 1978), which is the recommended method for calculating average long-term soil loss (G) in the Czech Republic and abroad. In terms of implementation of erosion control measures set according to GAEC requirements in LPIS, a new procedure has been developed for farmers to adjust cropping patterns and agronomic practices within the limits of allowable soil loss in a simple way.

The study was supported by research projects No RO 0223, QK 201010328, QK 21010191, SS 05010211 and SS 06010290.

**HYDRODYNAMIC CHARACTERISTICS OF SNOWMELT RUNOFF**

S. FU, B. LIU, H. MA, L. DONG

Beijing Normal University, Beijing, CHINA

Snowmelt erosion is one of the main types of erosion in cold regions at high latitudes or high altitudes. Increasing global temperatures can exacerbate snowmelt erosion. Flow velocity and flow resistance is important parameters for snowmelt erosion process and hydrological simulation. The purpose of this study was to investigate hydrodynamic characteristics of snowmelt runoff. The experiments were conducted in the furrow of the Jiusan watershed, Nenjiang County, Heilongjiang Province, China. The flow discharge and flow velocity were observed on slopes ranging from  $0.5^\circ$  to  $2^\circ$  during the snowmelt period. A total of 109 events were obtained. The measured flow velocities varied from 0.07 to 0.71 m/s, and the flow discharge rates varied from 0.008 to  $1.831 \times 10^{-3}$  m<sup>3</sup>/s. The results show that the flow velocity during the snowmelt period was significantly correlated with the slope gradient at the significance level of 0.05. The flow velocity increased with flow discharge as a power function. The coefficients varied with slope gradient, which indicates slope gradient had effects on the relationship between flow velocity and discharge. The Darcy-Weisbach friction factor decreased with Reynolds number as a power function at all slope gradients. Manning's formula can be applied to calculate flow velocity for the snowmelt runoff. Both Manning's n and Darcy-Weisbach friction factor were not constants, decreased with flow depth when the flow depth was less than 2 cm, and tended to stabilize when the flow depth was more than 2 cm. Hopefully, these results can be helpful for hydrological and soil erosion simulations during the snowmelt period.

**Keywords:** Snowmelt erosion, Flow velocity, Darcy-Weisbach friction factor, Manning coefficient

### EVALUATION OF WEPP (WATER EROSION PREDICTION PROJECT) HILLSLOPE MODEL USING SURFACE RUNOFF AND EROSION DATA FROM A SOIL WITH VERTIC PROPERTIES UNDER DIFFERENT CROPPING SYSTEMS

S PELLEGRINI<sup>1</sup>, F ROCCHI<sup>1</sup>, A ORLANDINI<sup>1</sup>, R NAPOLI<sup>2</sup>, N VGNOZZI<sup>1</sup>

<sup>1</sup> CREA-AA, Council for agricultural research and economics, Research Centre for Agriculture and Environment, Florence, ITALY

<sup>2</sup> CREA-AA, Council for agricultural research and economics, Research Centre for Agriculture and Environment, Rome, ITALY

The Water Erosion Prediction Project (WEPP) model is a physically based computer simulation program used worldwide to simulate runoff and soil erosion, both at hillslope and watershed level. However, its applications in Mediterranean pedoclimatic environment are few.

The performance of the WEPP model in simulating runoff and soil erosion was evaluated using input data from experimental plots under different soil use and management systems. The model was tested using data from a study carried out in the nineties of the last century, aimed to quantify the effects of different soil uses on runoff volume and soil loss at plot scale. The plots (75 x 15m) were in the S. Elisabetta experimental farm (Vicarello, Volterra) of the CREA-AA. In this study four treatments were compared: 1) winter wheat (*Triticum durum* Desf.), 2) alfalfa (*Medicago sativa* L.) meadow, 3) agropastoral system with Sulla (*Hedysarum coronarium* L.) and grazing saltbush (*Atriplex halymus* L.), 4) 20-year-old Mediterranean maquis. The soil is a silty clay loam Vertic Xerochrept in which shrinking and swelling phenomena regulate the hydrological behaviour.

The simulation results before and after model calibration were compared to measured runoff and soil erosion values. Both the estimated runoff and soil loss showed poor predictive capacity of the uncalibrated model, as highlighted by negative values of the Nash-Sutcliffe efficiency index. The comparison between the amount of eroded soil simulated by the uncalibrated WEPP, and the measured one, highlights how in such a pedologic environment the model overestimates soil loss.

The improvement in the predictive performance of the model after calibration, evidenced by values of RRMSE index considered "good" and "fair" when related to the more protective land uses, seems to demonstrate a satisfactory reliability of WEPP in identifying management scenarios able to mitigate soil loss.

Future WEPP application efforts need in-depth assessment, and proper calibration and parametrization of soil erodibility factors to improve erosion prediction in environments characterized by soils with a similar hydrological behaviour.

**EROSIVE PROCESSES IN TOPOSEQUENCES IN NORTHWESTERN PARANÁ, BRAZIL**

C.M. BONIFÁCIO, H. SILVEIRA, R.M. SANTOS, M.T. NÓBREGA

State University of Maringá, Maringá, BRAZIL

In Northwestern Paraná, Brazil, a significant interrelationship between pedological systems and susceptibility to erosive processes is observed. A detailed study was conducted to understand this interplay, focusing on two toposequences in the municipality of Tamboara, Paraná, mapping the toposequences of the soil samples collected. This region is characterized by Cretaceous volcanic outpourings of the Serra Geral Formation, overlaid by sedimentary rocks from the Caiuá Formation. The methodological approach was based on the Bi-dimensional Analysis model of Pedological Coverage proposed by Boulet et al. (1993) with geoprocessing techniques through ArcGIS. Toposequence I, named Tamboara, comprises Ferralsol (medium texture), Haplic Lixisol, Ferralic Arenosol, and Gleysol. The presence of Haplic Lixisol and Ferralic Arenosol, even in areas with gentle slopes, increases vulnerability to erosive processes. This is evidenced by rill and gully erosion observed along the slope, which is covered with cassava crops. Toposequence II, named Anhumai, extends along a slope in the Anhumai river valley, with the pedological system composed of Ferralsol, abrupt Haplic Lixisol, and Lithic Leptosol. The study reveals that despite the morphological characteristics of the Tamboara Plateau's relief, marked by gentle slopes, there are zones highly susceptible to erosion due to the composition and evolution of pedological systems. Particularly, concave base slopes with Ferralic Arenosol contribute significantly to this vulnerability. In the more dissected Anhumai valley, moderate to steep slope segments, coupled with lithological changes contrasting sandstone and basalt, create layers with varying resistance to weathering. This also influences slope dynamics, contributing to the high vulnerability observed. The identified pedological system reflects greater complexity in the structure and composition of this type of slope.

**FROM PIXELS TO PREDICTIONS: HARNESSING GIS AND REMOTE SENSING FOR SOIL EROSION ASSESSMENT  
IN THE UMNGENI BASIN, SOUTH AFRICA**

D. KIBIRIGE, N. BYARUHANGA

University of KwaZulu Natal, Pietermaritzburg, SOUTH AFRICA

Soil erosion is a major issue that causes significant harm globally, leading to the loss of land that can be used for agriculture and the blocking of waterways. The uMngeni basin is particularly vulnerable to soil erosion due to heavy rains that eventually cause floods. One way to estimate soil erosion is through soil modelling approaches, which provide a quantitative and realistic spatial estimate of soil erosion. This study used the Revised Universal Soil Loss Equation (RUSLE) model along with remote sensing and GIS methodologies to evaluate soil erosion risk within the uMngeni basin. The aim was to identify areas that are prone to flooding and provide useful information for disaster management. Soil physical properties, rainfall data, land use/land cover maps, and terrain attributes were integrated into GIS software to identify zones that are susceptible to erosion. The study classified the basin into six severity classes based on soil loss rates (t/ha/year): Low (0-7), Moderate (8-15), High (16-25), Very High (26-45), Severe (46-60), and Very Severe (>60). The findings revealed that the lower plain of the basin experienced minimal soil loss, primarily below 7 t/ha/year. Conversely, higher elevations in the uMngeni basin exhibited higher erosion rates, primarily influenced by topographical factors, resulting in an exceedance of 60 t/ha/year of erosion. The pixel-level assessments using the RUSLE model showed a correlation between erosion-prone zones to historical flood regions. Notably, regions surrounding the uMngeni River valley exhibited severe erosion risks exceeding 45 t/ha/year, highlighting new flood-prone regions. Therefore, these findings can provide timely insight to inform disaster management agencies' policymakers in implementing targeted soil management and conservation strategies within the basin, thereby mitigating erosion risks and fostering sustainable land use practices to minimise floods as a result of human activities.

<sup>4</sup> University of Zurich, Zurich, SWITZERLAND

<sup>5</sup> Dartmouth College, Hanover, USA

<sup>6</sup> Syracuse University, Syracuse, USA

<sup>7</sup> Virginia Tech, Blacksburg, USA

Accelerated soil erosion and deposition processes pose major threats to soil health and ecosystem services in forested landscapes, particularly following intensive practices such as whole-tree harvest. These disturbances drastically alter soil dynamics, leading to increased soil erosion and deposition rates, which subsequently affect soil properties and carbon storage. At the Hubbard Brook Experimental Forest (HBEF) in NH, US, a whole-tree harvest experiment was conducted from 1983-1985 in a small watershed to evaluate the long-term impacts of deforestation on the carbon budget, soil properties, cycling of nutrients, and vegetation regrowth. Our prior study at HBEF assessed the impact of whole-tree harvesting on soil redistribution rates using <sup>239+240</sup>Pu isotopes in areas covered by tree harvest residues and uncovered. We found no erosion or deposition rates on sites located at the shoulder and upper backslope that were covered by tree harvest immediately after deforestation and concerning erosion and deposition rates at the uncovered mid backslope and toeslope sites, respectively. Those findings represent an average of approximately 60 years of redistribution processes, a timespan that covers Pu measurements. In this study, we investigate the immediate and enduring impacts of such practices within the HBEF by quantifying soil erosion and deposition rates in sites with residual harvest debris compared to those cleared immediately post-harvest. This study aims to discern the protective role of woody residue against soil erosion immediately following deforestation and to track the trajectory of erosion rates through a longitudinal study extending to 2022/23. By integrating re-sampling techniques and <sup>239+240</sup>Pu isotope analysis, our findings seek to establish a clearer understanding of soil dynamics post-harvest and contribute to the development of forest management strategies that promote soil health and carbon sequestration.

<sup>2</sup> Tokaj Research Institute for Viticulture and Oenology, HUNGARY

<sup>3</sup> Hungarian University for Agriculture and Life Science (MATE)- Karcag Research, HUNGARY

The Tokaj Wine Region is situated in Northeastern Hungary, consisting approximately 5500 hectares of vineyards. The majority of the plantations, especially for quality winemaking, are cultivated on steep slopes, and around 10% of the area, mainly around the Tokaj Hill, also lies on loess-based soils. In these sites risk of erosion is considerably high. Observing the last few decades, occurrence of heavy rainfalls and long dry periods are both getting more frequent. Although weed control is increasingly done by mechanical methods considering the harmful effects of herbicides on soil microbiome, opening the soil surface also induces erosion. Through several research projects in the Tokaj Research Institute for Viticulture in Enology, we examined erosion susceptibility of soils on different vineyard sites and its connection with shallow mechanical cultivation and soil water content, which led to the design of improved soil/cover crop management regimes against erosion. During the 2018 season, two sites with loess and another with volcanic base rock were compared using Eijkelkamp 09.06 rain simulator. As treatments, artificial moisturization and presence/absence of shallow cultivation were applied. According to our measurements, the frequently cultivated surface showed much higher soil loss during the simulated rainfall. Additionally, erosion susceptibility increased if the topsoil water content was near field capacity in the beginning of the simulated rain event. As an advice to growers, we formulated that frequent topsoil cultivation better be avoided during the vegetative season, especially in the case of steep sites and physically degraded soils with lower organic matter content. Furthermore, rationally executed cover crop cultivation could have beneficial effects such as protection against erosion and better structure, while competition for available water for grape plants is negligible.

### DIGITAL SOIL MAPPING FOR ENHANCED SOIL ORGANIC CARBON MANAGEMENT USING ORDINARY KRIGING AND SUPPORT VECTOR MACHINE APPROACHES

S. DE CAIRES<sup>1</sup>, A. KESHAVARZI<sup>2</sup>, E. BOTTEGA<sup>3</sup>, F. KAYA<sup>4</sup>

<sup>1</sup> Department of Food Production, St Augustine, TRINIDAD - TOBAGO

<sup>2</sup> Laboratory of Remote Sensing and GIS, Department of Soil Science, University of Tehran, Tehran, IRAN, ISLAMIC REP

<sup>3</sup> Federal University of Santa Maria (UFSM), Cachoeira do Su, BRAZIL

<sup>4</sup> Department of Soil Science and Plant Nutrition, Faculty of Agriculture, Isparta University of Applied Sciences, Çünür, TURKEY

Effective management of soil organic carbon (SOC) holds immense importance in fostering sustainable agriculture and combatting climate change. In the Neyshabur plain of northeastern Iran, the pressing issue of spatially varying critically low SOC levels prompted the development of management zones (MZs) tailored for site-specific SOC management. This study involved collecting soil samples (0-0.3 m) alongside geomorphometric variables derived from a digital elevation model at 288 locations. Significant correlations ( $p < 0.05$ ) were established between SOC and key factors such as soil pH, clay content, available phosphorus, available potassium, and vertical distance to the channel network. Utilizing support vector machine (SVM) and ordinary kriging (OK) methods, the spatial variability of SOC and its associated pedo-geomorphometric variables were used to generate digital soil maps, facilitating the creation of MZs for targeted SOC management. While the R<sup>2</sup> and RMSE of both OK and SVM models were comparable, more accurate MZs were derived from the SVM model, as indicated by the Fuzzy Performance Index (FPI = 0.091) and Normalized Classification Entropy (NCE = 0.113) compared to OK (FPI = 0.135, NCE = 0.164). The study revealed the potential of both approaches for site-specific SOC management, yet a significant average difference of 0.8 g kg<sup>-1</sup> SOC between SVM and OK ( $p < 0.05$ ) was observed, particularly along transitional MZ boundaries. Consequently, the SVM-based MZs stand out, offering enhanced accuracy for precise application of organic amendments, mineral fertilizers, and management practices. These findings provide a robust framework for improving carbon sequestration and mitigating chemical contaminants in the Neyshabur plain of Iran.

### INFLUENCE OF THE SAMPLING DESIGN IN THE SOC STOCK ESTIMATION: ACCURACY AND UNCERTAINTY IN SOIL MAPPING

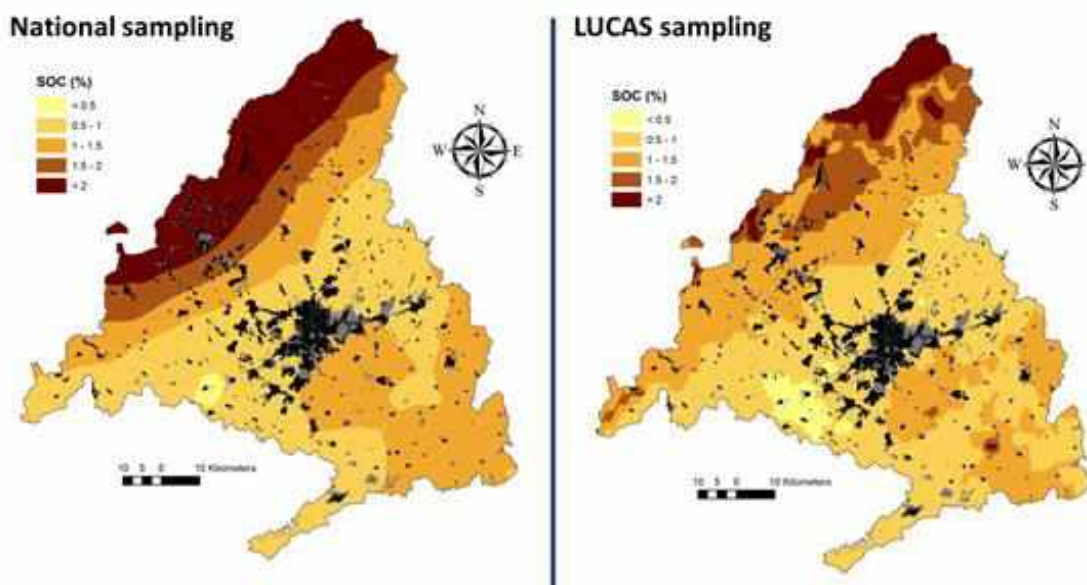

J.A. RODRIGUEZ MARTIN <sup>1</sup>, R. BOLUDA <sup>2</sup>, J. PRO <sup>1</sup>, A. LAZARO <sup>1</sup>, M. DELGADO <sup>1</sup>, N. OCAÑA <sup>1</sup>, P. BEJAR <sup>1</sup>, J.L. GABRIEL <sup>1</sup>

<sup>1</sup> INIA-CSIC. Madrid, department of environment. Madrid, Spain, Madrid., SPAIN

<sup>2</sup> Universidad de Valencia. Dept. Biología Vegetal. Valencia, Spain, Valencia, SPAIN

Soil organic carbon stock (SOCS) assessments are essential in the climate change mitigation role to adopt practices focused on increasing the carbon content in soils. However, this depends on the information that we have processed. While the variability in laboratory analysis methods in the determination of organic carbon are well defined, the variability in field sampling is often not known. The present study analysed the spatial distribution of SOCS and evaluated two soil sampling protocols in field. We sampled all Lucas points in the autonomous community of Madrid (Spain) and including sampling in the national network close to the Lucas locations using both sampling protocols (National and LUCAS). A total of 121 sampling plots and 242 soil analysis samples were performed. The carbon content evaluated in soil is higher in the national sampling protocol (mean 1.165%) than in the field protocol used in Lucas (mean 1.051%). were utilized to determine significant effect on sampling design (Lucas and Spanish National protocol) and no statistically significant differences were found between both sampling designs. However, ANOVA analysis ignore the spatial component. The information obtained from the Spanish national design presents a greater spatial correlation. This is possibly motivated because in the Spanish sampling design were collected 21 subsamples from each plot in a surface area of 2500 m<sup>2</sup> versus 5 subsamples in an area of 16 m<sup>2</sup> in the Lucas field protocol. The prediction standard errors quantified the degree of uncertainty for each location on the surface. The standard errors map showed lower errors in the uncertainty kriging maps obtained with the Spanish national sampling protocol. As synthesis, the way of taking field samples, the number of subsamples, the surface sampled and the sampling depth are very important factors that must be taken into account in the determination and analysis of carbon maps.

### EXAMPLES OF USE OF GIS FOR THE STUDY AND MANAGEMENT OF SOILS

S. BRAVO<sup>1</sup>, C. PEREZ DE LOS REYES<sup>1</sup>, R. JIMENEZ BALLESTA<sup>2</sup>, F.J. GARCIA NAVARRO<sup>1</sup>

<sup>1</sup> Universidad de Castilla-La Mancha (ETSIA), Ciudad Real, SPAIN

<sup>2</sup> Universidad Autonoma, Madrid, SPAIN

Geographic Information Systems Programs (GISP) are systems that use technology to combine the knowledge of experts and those who have experience, in a project, work or study. This technology makes it possible to manage, evaluate and visualize a large amount of information with spatial dimension, which help to better understand the various variables that affect the decisions that must be made. GISPs present some drawbacks that have motivated research on such systems to improve performance, often related to online tools.

GISP have important applications for the study of soils and the production of maps in both the cartographic and agricultural fields. Thus, they allow to generate thematic maps that represent classes of crops, types of cultivated soil, information on irrigation or climatic aspects. The ability to overlay different layers provides the capacity to combine different maps and address more complex problems by combining more information into a single map.

This work presents examples of soil maps made with ArcGIS® (licenced by University of Castilla-La Mancha) in several areas of Castilla-La Mancha (Spain). The variety in the type of maps and parameters represented (types of soils, distribution of major and trace elements, general soil properties, moisture retention properties, etc.) allows to approach the potential of this type of instruments to communicate scientific information effectively and simply.

### ASSESSMENT OF SOIL ORGANIC CARBON FOLLOWING WILDFIRES IN NORTHERN EVIA, GREECE: A DIGITAL SOIL MAPPING APPROACH

N.L. TSAKIRIDIS, N. SAMARINAS, E. KALOPESA, D. XENITOPOULOU, D. PALANTZA, G. ZALIDIS

SpectraLab Group, Laboratory of Remote Sensing, Spectroscopy & GIS, Aristotle University of Thessaloniki, Thessaloniki, GREECE

This study delves into the aftermath of a wildfire incident in August 2021, exploring its impact on soil characteristics, with a specific focus on soil organic carbon (SOC) within the diverse terrain of Northern Evia, Greece. Utilizing open Copernicus data and specifically data from the Sentinel-2 constellation, the European Digital Elevation Model (DEM), we executed a digital soil mapping analysis spanning agricultural fields affected by wildfire. The study area encompasses an area of 28 square kilometers with 45% of the crops being olive groves, 16% various grains, 10% animal feed, 10% are fallows, 4% other tree crops (e.g., nuts, figs, etc.), and rest are mostly horticulture. This area was adjacent to a mountainous terrain covered with forests that was burned down in the experienced wildfires; our goal was to map the SOC of these croplands after the wet deposition of post-fire residues. Sampling was performed by examining bare soil reflectance composites and performing clustering for the seasonal crops, while random sampling was conducted for perennial crops. We collected 40 soil samples and subsequently analyzed them in the laboratory to quantify SOC levels. To generate the map representing the conditions post-wildfire, the Random Forest (RF) learning algorithm was employed using leave-one-out cross-validation to infer SOC from Sentinel-2 and DEM data, and we masked the image using the scene classification layer of Sentinel-2 and the 2018 CORINE Land Cover data. RF attained an accuracy of estimation of RMSE 1.45 g C / kg, R<sup>2</sup> of 0.56 and RPIQ of 2.18. Through the amalgamation of satellite-based assessments and laboratory-validated soil measurements, our research offers a comprehensive overview of the alterations in SOC distribution following the wildfire event. The detailed mapping conducted after the wildfire stands as a crucial contribution to understanding the spatial and temporal variations in soil properties and erosion susceptibility within the wildfire-affected region of Northern Evia, Greece.

<sup>3</sup> National Research Council of Italy - (CNR-ISSIA), Bari, ITALY

<sup>4</sup> GRUMETS Research Group, CREAM, Bellaterra, SPAIN

Processes related to land degradation have significantly increased in the last few decades which is likely to further increase if no actions are taken. The need for adopting practices to mitigate and restore degraded lands have been emphasized by the new Soil Strategy. To guide actions through a consolidated framework, a cost and time efficient approach is needed. Six pilot sites in southern Europe, selected within the NewLife4Drylands (NL4DL) project were examined, by both available field data and satellite-acquired data, for monitoring degradation and ongoing restoration activities to be improved and transferred to similar degraded sites. As part of the project, a web-based tool and a restoration protocol have been proposed with the aim of providing a reference procedure for specific degradation processes to monitor restoration activities based on nature-based solutions. This decision support tool considers various factors such as degradation processes, remotely sensed and physical indicators, and commonly used nature-based solutions. Connections between these variables, which form the basis of the logical-relational map of the tool, have been initially collected among the internal knowledge of the project and can be further developed and detailed using a larger sample of experts on the topics of different related disciplines such as soil and environmental sciences. The decision-making tool provides a workflow to guide the end-users in the field of environmental management and planning, through the identification of processes leading to land degradation, the selection of monitoring indicators viable and the most suitable nature-based solution for that particular process. The tool will be used as an input for an action protocol at local and regional scale for environmental management and planning. This kind of semantic and logic model can be used to generate a range of possible monitoring approaches, evaluating their potential effectiveness, exploiting the connections with other existing web tools for the on-the-fly calculation of remote sensing indicators and with any dedicated tool aiming to predict the impact of restoration activities.

<sup>3</sup> Agurotech B.V., Amsterdam, THE NETHERLANDS

European agriculture is becoming increasingly dependent on irrigation as a result of climate change and agricultural intensification. At the same time, the availability of irrigation water is limited or decreasing because of recurrent droughts, while increasing reliance on non-conventional water resources poses additional pressure on agricultural productivity (e.g. soil salinity). The Future of Farming LIFE project addresses this issue by demonstrating the benefits of data-driven precision agriculture technologies and promotes their use to achieve a more intelligent water use at the field or farm scale. During 2023 the technology was deployed and tested in 30 farms in two agricultural areas in Spain in a wide range of crops. The technology consists of a field- and weather data-driven soil water and crop model that predicts soil water content throughout the growing season. Irrigation recommendations are delivered to the farmers through a mobile phone application. Self-contained sensors that monitor soil water content, bulk electrical conductivity and temperature at depths of 0.15 and 0.30 m were installed at each field and reported automatically to a central server. An analysis of the measured data and the delivered irrigation recommendations is provided and linked with agricultural management-related information and crop yield. Results show that country-specific connectivity adaptations are needed for rolling out precision farming technologies in the EU, while the implementation of the irrigation recommendations by farmers is dependent on crop type, water availability and mandatory regulations (e.g. nitrate vulnerable areas).

### DIGITAL MAPPING OF SOIL QUALITY FOR AGRICULTURAL PURPOSES IN ROMANIA

C.V. PATRICHE, B. ROSCA, R.G. PIRNAU, I. VASILINIUC

Romanian Academy, Iasi Branch, Center for Geographical Research, Iasi, ROMANIA

The Romanian methodology of soil quality assessment for agricultural purposes comprises 17 factors, of which 2 are climate factors (mean annual temperatures, corrected to account for slope and aspect influences; mean annual precipitations, corrected to account for slope and soil permeability influences), 4 are terrain factors (slope, landslides, flooding, surface moisture excess) and 11 are soil factors (gleyic, stagnic properties, salinization / alkalization, texture, pollution, groundwater level, porosity, calcium carbonate content, pH, edaphic volume, humus reserve). Each factor is assigned a suitability score, ranging from 0 to 1, which varies according to the specific crops, then the scores are multiplied to obtain the soil quality index, ranging from 0 to 100. Our study performs for the first time an accurate digital mapping of the suitability factors and the resulting soil quality index for the entire Romanian territory, using recent climate data (1990-2019). The CHELSA database was used to derive the climate factors, and the 25 m EU-DEM to derive terrain slope and aspect. We further used the European LUCAS soil database to derive soil humus reserve, CaCO<sub>3</sub> content, pH, and the spatial distribution of wells water depth to interpolate the groundwater level. The other soil properties were inferred based on the digital soil map of Romania in vector format. Finally, we integrated the suitability factors and achieved the soil quality index map of Romania for the main crops. Because the multiplication procedure used to achieve the soil quality index has some limitations, we also tested other methods of factors' aggregation. All the data achieved in our study constitute a GIS database which will be made available to soil surveyors and other interested researchers and institutions, to assist them in making more accurate evaluations of agricultural land.

Acknowledgements. This research has benefitted from the support of the PN-III-P4-PCE-2021-1350 project, funded by the UEFISCDI program, Romania.

### MAPPING SOIL HEALTH AT REGIONAL SCALE: DISENTANGLING DRIVERS AND PREDICTING SPATIAL LAND USE EFFECTS

V. RUBIO<sup>1</sup>, J. AMSILI<sup>2</sup>, D. ROSSITER<sup>2</sup>, A. MCDONALD<sup>2</sup>, H. VAN ES<sup>2</sup>

Soil health (SH) is inherently dynamic, and its cross-scale and temporal variability presents challenges to understanding its drivers. We applied digital soil mapping (DSM) techniques to integrate SH observations with remotely-sensed data, representing the main soil forming factors and short and mid-term cropping and management, using machine learning (ML) models for regions in New York State. Four soil biological (soil organic matter, POXC, protein, and respiration) and two physical (water aggregate stability and available water capacity) soil indicators as well as a composite SH index were evaluated to 1) analyze relationships among climate, inherent soil properties, and land use to SH indicators across NY State and regions within; 2) develop data-driven models for predicting and mapping SH indicators at regional scale; and 3) use the generated models to estimate impacts from hypothetical regional land use change scenarios. The approach proved to be an effective strategy for modeling SH indicators (average  $R^2=0.58$ ). Disentangling the role of land use types and crop management on SH indicators explained, on average, 42% of SH variation and showed, among others, positive effects of perennial forage crops and biomass production and adverse effects of intensive vegetable production, which highlight the important role of biomass production and recycling. Modeled hypothetical land use changes at regional scale showed potential SH benefits from alternative cropping systems. Overall, geospatial application of ML models to mapping SH provides insights into its drivers, and can support management policies and interventions to improve SH.

The Global Soil Information System (GloSIS) web ontology is the latest milestone in a decade old effort towards a global soil data exchange mechanism. Following on initiatives such as the Australia-New Zealand Soil model, the ISO-28258 soil quality model, INSPIRE Soil Theme and the OGC Soil Interoperability Experiment, this web ontology proposes an operational approach to data exchange. Leveraging the W3C specifications for the Semantic Web, OGC geospatial standards and implementing the ISO domain model, GloSIS includes code-lists of soil properties, soil description vocabularies and analytical procedures. It re-uses important standards, like the SOSA, GeoSPARQL, QUDT and SKOS web ontologies, and links to existing vocabularies: DBpedia, International Chemical Number (InChi) and PubChem. The ontology uses persistent and resolvable identifiers, ensuring sustainability over time. GloSIS codelists terms are resolving to their human and machine-readable definitions in the OGC rainbow server. With its Semantic Web approach, the GloSIS web ontology fulfils the ambition for a federated system as initiated by the GlobalSoilMap and later laid out by the Global Soil Partnership in its Action Plans (Pillars 4 and 5).

A broader trend is emerging towards the adoption of the Semantic Web, making GloSIS an important component in the exchange of environmental and sensed data. The OGC now aims to publish all domain models supporting its standards as web ontologies. The JSON-FG and Agriculture Information Model specifications are precursors in this regard. Also of note is its joint work with the W3C to align SOSA with the novel Observations, Measurements and Samples (OMS) standard. This alignment opens the path for the automated generation of APIs compliant with the SensorThings API standard from knowledge graphs.

This communication reviews the GloSIS web ontology and provides future steps towards its adoption and integration with emerging technologies. GloSIS has been developed, tested and used within several European research projects. The SoilWise project is currently evaluating its fitness for the repository of the European Soil Observatory platform.

Under the H2020 European Joint Research Programme EJPSOIL (<https://ejpsoil.eu/>), the working package 6 aimed at supporting harmonised soil information and reporting. A so called “Software framework for a shared agricultural soil information system”, deliverable EJP SOIL\_D6.4, was produced aimed at enabling transcoding and streamlining of interoperable and harmonised national agricultural soil data into ESDAC (<https://esdac.jrc.ec.europa.eu/>), as foreseen in the Grant Agreement, and by general terms enabling INSPIRE compliant soil data sharing. The EJPSOIL\_D6.4 builds on the solid foundations of the INSPIRE Directive, taking advantage of the latest developments in the process of modernisation and simplification of its technical requirements in the wider context of the European Strategy for data and the Green Deal Data Space. Key components of the EJPSOIL\_D6.4 are a streamlined soil database in GeoPackage encoding format, optimized in view of data compliance to INSPIRE; a data transformation and harmonisation processes; a semantic harmonisation and code list management procedures and tools. The GeoPackage is an SQLite database container that can store both vector and raster data as well as non-spatial data, is a portable, lightweight, and widely compatible across environments, especially efficient where connectivity and bandwidth are limited, and has the advantage to be portable, and can be used directly into GIS applications, such as QGIS. Since November 2022, with the official endorsement of a related INSPIRE Good Practice, the GeoPackage can be used as an alternative (to GML) encoding for the delivery of INSPIRE datasets. In accordance with the INSPIRE Good Practice for the “GeoPackage encoding of INSPIRE datasets”, a logical model for the GeoPackage encoding of Soil data has been developed, starting from the INSPIRE conceptual model and with reference to the classes implemented in the EJPSOIL\_D6.4. The model will be made available to the wider INSPIRE community via the INSPIRE Helpdesk and will effectively become a template for those INSPIRE implementers who choose to deliver INSPIRE soil data using the geopackage format.

More than 30% of the continental surface area is affected by wildfires. Fires are strongly influenced by natural climatic phenomena such as El-Niño episodes and are increasing in response to the current climate change. Fires represent a real threat to the functioning of soils and the quality of water resources, as they can promote the mobility of trace metal elements and disrupt the biogeochemical cycle of sulfur in wetlands. A drinking water catchment (DWC) in the Ile des Pins, South of the New Caledonia archipelago, has been studied after it experienced Ni contamination following a drought and wildfires in 2019. A series of dolines feed this DWC, that can be either filled with water in wet season or dry after drought. Soils developed from ultramafic rocks are naturally rich in Ni and Cr. Consequently, the Gleysols developed in the studied wetlands present significant metal contents and substantial amounts of sulfur that could indicate potential sulfidic accumulation at depth. Some studies have highlighted the risk of Acid Sulphate Soil (ASS) formation in case of wildfires in similar sulfidic wetland settings.

Water monitoring (2020-2021) in the studied burned doline showed strong acidification associated with high concentrations of Ni and SO<sub>4</sub>. The mineralogical characterization of the sediments and analysis of Ni speciation allowed evidence of Ni-hexahydrite and Ni/Fe-sulfides as the major Ni-bearing mineral species. Although sulfides are common species in wetlands, the occurrence of Ni-hexahydrite was considered to result from drought and wildfires. When the doline has been refilled, the dissolution of Ni-hexahydrite has led to high Ni concentrations at the DWC downstream of the doline. Nickel and S isotopes show that the Ni contamination at the DWC can be directly related to enhanced Ni sulfide oxidation in the Gleysol.

Droughts and wildfires in wetlands from Ile des Pins can lead to the formation of inland ASS and further cause Ni contamination of freshwater because of the naturally high Ni background.

**META-ANALYSIS OF WATER-DISPERSIBLE COLLOID EXTRACTION METHODS: UNRAVELING TRENDS AND ADDRESSING METHODOLOGICAL GAPS FOR STANDARDIZATION**

J.C. CACEREZ, A. DE MATTEIS, R. CHIARELLA, A.E. BERNS, L. WEIHERMÜLLER, N. SIEBERS

Institute of Bio- and Geosciences, Agrosphere (IBG-3), Forschungszentrum Jülich GmbH, Jülich, GERMANY

Water-dispersible colloids (WDC) play a crucial role in various soil processes, including nutrient storage, transport, and release from the root zone, with implications for agricultural and forest ecosystems. Hence, it is essential to understand their dynamic behavior and characteristics. The measurement and characterization of WDC in soils establishes a foundation for understanding their properties. However, there is a lack of consensus in literature regarding the extraction method for WDC and the size range defining colloids. This study aims to uncover gaps and identify trends in the heterogeneity of conventional methods for WDC extraction reported in literature and to pinpoint suitable operations for WDC extraction. Therefore, a meta-analysis was performed, where reported data such as sample information, soil physicochemical properties, WDC content, and separation methods, were extracted from selected empirical studies (N = 27) yielding 292 datapoints. Principal component analysis was applied to 28 variables with complete data to identify the most relevant methodological variables for extracting WDC in soils. The first nine principal components (PC) cumulatively explain 85.6% of the variance in the dataset and were interpreted. Methodological variables, such as sample moisture condition, sample preparation, shaking dispersant, shaking speed, soil-dispersant ratio, separation methods, and WDC drying methods, exhibited contributions higher than the uniform contribution of the variables to the relevant PC, indicating that these variables highly influence the overall structure and patterns within the dataset. Differences in these variables were experimentally assessed using soils collected from various land uses (forest, arable, and grassland) to determine their impact on WDC content and composition. The results of this study emphasized the need for a standardized approach to WDC extraction in soils for comparability between studies. The identified influential variables and their impact on WDC in soils can contribute to addressing the methodological gaps and can serve as a foundation for improving the existing protocols for WDC extraction and its application for diverse soil environments.

### TOOLS FOR IMPROVING LABORATORY PRACTICES IN SOIL SCIENCE AND ENVIRONMENT

C. PÉREZ-DE-LOS-REYES, S. BRAVO

UNIVERSIDAD DE CASTILLA LA MANCHA (E.T.S.I.A.), Ciudad Real, SPAIN

Interdisciplinary knowledge is needed to recognize the role of soil in agricultural and agri-food engineering. The subjects of Soil Science and Climatology and Environmental Science and Technology taught in the Degrees of Agricultural and Agri-Food Engineering and Enology, at the High Technical School of Agricultural Engineers of Ciudad Real (Spain), aim at knowledge of the soil as a productive and ecological factor. Laboratory practices are essential training activities in the development of skills in these soil subjects.

From the experience learnt by teachers in these activities, it is deduced that a large part of the students does not prepare for the practices before the sessions (they do not read the scripts) and limit themselves to following the guidelines of the teacher's explanation automatically, without understanding what they are doing and why they are doing it. This attitude makes it difficult to acquire skills and turns practices into a requirement that "must be done and passed" without taking advantage of the benefits that this activity has for autonomous and directed learning. Furthermore, students do not appreciate the importance of laboratory data in soil and environmental knowledge.

In this context, the professors responsible for these subjects have developed (during the 2021-2022 and 2022-2023 academic years) tools that, when applied in the laboratories of the subjects of both degrees, allow for the improvement of the teaching-learning process in laboratory practices. To achieve this, the following tools have been used: review and improvement of the practice scripts (using symbols that identify the type of skills that are acquired), on-line test before the start of the practical sessions in the laboratory, photographs competition, posters for evaluation and final questionnaires (carried out with Microsoft Forms) to evaluate the actions of the new tools. This work explains how these tools were developed and the students' assessment of them.

### THE CREA SOIL ARCHIVE, A NATIONAL COLLECTION FOR ITALY: MUNSELL SOIL COLOR AS A PROXY TO DEFINE A REPRESENTATIVE AND ROBUST SPECTRAL LIBRARY

G. L'ABATE <sup>1</sup>, R. BARBETTI <sup>2</sup>, C. FONDON LOZANO <sup>1</sup>

<sup>1</sup> CREA, Agriculture and Environment, Firenze (FI), ITALY

<sup>2</sup> CREA, Forestry and Wood, Casale Monferrato (AT), ITALY

Archives storage samples for long-term preservation. Physical samples are basic elements for reference, study, and experimentation. There is an urgent need for better integrating these physical objects into the digital research data ecosystem, to support research, retrieval, analysis, reuse, preservation and scientific reproducibility.

The CREA collection, located at the Fagna Experimental Farm, Scarperia (FI), stores specimens and associated metadata. It covers all major agricultural and forestry soil landscapes in Italy for organic and mineral horizons. Parameters include particle size, pH, organic carbon, and total carbonates. For the present work, a very limited number of specimens (51) was selected based on the field described Munsell Soil Chart color. Specimen has been characterized by imaging spectroscopy using an ASD FieldSpec 3, according to the procedure defined by the Standard Protocol and Scheme for Measuring Soil Spectroscopy (IEEE SA). Further spectra elaboration allowed to obtain Cielab colors and extract the white, red, green, yellow pigment fraction and contrast value DeltaE. The selection interested 11 different projects ranging from 1986 to 2017. 10 different Hue colors were extracted, the most represented being the 10YR with 14 samples and the least the 5YR and 5PB with just one each; Value 6 resulted the most represented while 1 & 10 occurred just once; With Chroma, 1 to 4 were frequent while 5, 10 & 12 occurred once. Just one resulted to be an organic horizon (Oi) while others resulted mineral surface A horizons (11), E (2), B (19), C (10). Soil properties resulted ranging for Clay: 0.9-93 (41); Silt: 0.3-70.9 (41); Sand: 1-97.4 (41); Bulk density: 0.49-1.69 (10); pH (water): 4.9-9.3 (39); Organic carbon: 0.03-11.41 (40); Total nitrogen; 0.01-1.3 (19); Total carbonates: 0.01-72.1 (29).

Although this oriented extraction demonstrated not to perfectly represent the original dataset, it offers a first attempt to create extraction criteria to define a both limited and robust spectral library. Further development will include selections based on other soil parameters.

MANAGEMENT OF NITROGEN FERTILIZATION IN SUGARCANE IN NINE CONSECUTIVE CYCLES: INFLUENCE ON PRODUCTIVITY AND SOIL QUALITY

A.C. VITTI <sup>1</sup>, I.A.M. DEGASPARI <sup>1</sup>, L. QUECINE <sup>1</sup>, L. VITTI <sup>1</sup>, H. CANTARELLA <sup>2</sup>

<sup>1</sup> São Paulo State Agency for Agribusiness Technology (APTA), Piracicaba, BRAZIL

<sup>2</sup> Soils and Environmental Resources Center, Agronomic Institute of Campinas (IAC), Campinas, BRAZIL

Soil nutrient imbalances and degradation can be the result of continuous high nitrogen applications. This research was designed to evaluate the effect of ammonium nitrate rates on technological parameters and soil fertility over consecutive cycles (nine ratoons or ten cycles). The design was in randomized blocks, with four replications, in a Red Oxisol at APTA, Piracicaba-SP Brazil. Among the treatments under different N levels zero, 60, 120 and 180 kg ha<sup>-1</sup> N, related to eight ratoons, and additionally to the subsequent harvest (9th ratoon) without nitrogen fertilization to all treatments to evaluate residual effects from previous cycles. Soil samples were collected in two periods (2016 and 2021), the last one carried out in November/2022, at depths of 0-10, 10-20 and 20-40 cm, 20 cm close to the sugarcane line. Nitrogen application during harvests 2014 to 2022, resulted in a significant increase in yield, except in relation to cycles 2015 (first ratoon), and 2021 (7th ratoon), drought conditions affected the crop yield. Medium (120 kg/ha) and high (180 kg/ha) N rates led to superior stem yields, consistently outperforming other treatments in the last years (2019, 2020, and 2022). The F-test revealed a significant difference between the medium and high N rates compared to the low (60 kg/ha) and control (zero kg/ha) treatments. In most cases, the higher nitrogen rate (180 kg/ha) resulted in a significant increase in soil acidity, including potential acidity (H + Al), and a decrease in soil fertility. Consequently, the high acidity associated with the higher N rate resulted in low N fertilizer efficiency. The residual effect was observed with the application of medium (120 kg/ha) and high (180 kg/ha) N rates. The 5th, 6th and 8th ratoons proved to be effective in agronomic terms as a result of the efficiency of residual nitrogen in the following 9th ratoon-10 cycle in the absence of N fertilization, high productivity in relation to the low N rate.

Table 1. Sugarcane productivity of the control treatment (without N application) and of the ammonium nitrate - "AN" treatments - plant cane 30, 60, 90 kg N ha<sup>-1</sup> and ratoons 60, 120, 180 kg N ha<sup>-1</sup>, respectively, corresponding to the low, medium and high doses of N, cycles 2014 to 2022. Residual cycle 2023 (with zero kg ha<sup>-1</sup> of N fertilization)

TREATMENT	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023
Control	104	102	111	74.6	66	75	79.0	66	73	60

### CO-EVOLUTION OF STRUCTURE, HETEROGENEITY, AND FUNCTION DURING PEDOGENESIS

K. TOTSCHKE

Department of Hydrogeology, Friedrich-Schiller-University, Jena, GERMANY

The development of soil structure and its linkage to functions have become a major research theme boosted by the increasing threat to soil health and fertility due to climate and land-use changes. Water retention, flow of fluids, matter dispersal, habitat provision, nutrient supply, organic matter and element storage are functions of soil fundamental to the life-sustaining ecosystem services. It is well accepted that soil's functions are intimately linked to its architecture and state of aggregation, the void network, and the composition and properties of the solid–fluid biogeochemical interfaces therein. Broad consensus exists that structure develops by the synergistic action of physical, chemical, and biological processes. Inspired by these insights, we see a growing number of research activities that focus on unraveling the intricate interplay and interdependence in search of a theoretical framework that allows for a fundamental understanding of the linkage of structure and function. Substantial progress has been achieved by experimental pedogenesis and the joint application of advanced spectroscopic, microscopic, and tomographic techniques, which enabled studying structure, composition, and biogeochemical interface properties already at the submicron scale. In line with this, modeling endeavors that give feedback to the experimental designs by testing various scenarios serve to explore the factors that govern the co-evolution of structure and function, or challenge concepts *in silico*, considerably improved over the last decade. This presentation compiles the current understanding of the interplay of abiotic and biotic forcings for structural dynamics and its consequences on the processes and functions in soils. It builds on synthesizing the evidence, findings, and outcomes of field surveys, computer simulations, and experimental pedogenesis. The findings, based on a combination of experimental, observational, instrumental and computational methods, pave the way for a profound understanding of the intricate processes involved in the fascinating coevolution of structure and function during pedogenesis.

### THE SHAPE OF SOIL CARBON PROFILES REFLECTS CLIMATICALLY DRIVEN RATES OF DECOMPOSITION AND VERTICAL TRANSPORT

A. RONALD, M. CHITZAH

University of California, Berkeley, USA

For over four decades, scientists have suggested that soil C and C isotope profiles are shaped by both rates of decomposition and vertical transport. Despite this theoretical framework, the application of these concepts to the interpretation of the vast number of soil C profile observations remains under-studied.

Here, we examine the shape of vertical soil organic C profiles along two climate gradients: one of rainfall and one of temperature in the central United States. Due to the latest Pleistocene loess parent material, virtually all other state factors are held nearly constant.

From a reaction-transport perspective, the rate that soil C declines with depth represents the ratio of the decomposition rate constant ( $k$ ) to that of the vertical transport constant ( $v$ ).  $k$  should vary strongly as a function of temperature, while  $v$  should vary strongly with rainfall.

The transects allow us to test these hypotheses, and indeed show that (as hypothesized) the rate that C decreases with depth increases with decreasing rainfall (due to decreases in  $v$ ), and with increasing temperature (due to increases in  $k$ ).

These data confirm that (1) vertical transport of soil C is a key process in the shape, and amount, of C in soil profiles at a given depth, and (2) it has large implications for the isotope (and radiocarbon) content of soil C.

### PEDOLOGY IN THE LIGHT OF SCIENTOMETRICS AND BIBLIOMETRICS

A. M. SIPOS<sup>1,2</sup>, S. NÉMETHY<sup>1,2,3,4</sup>

<sup>1</sup> University of Tokaj, Sárospatak, HUNGARY

<sup>2</sup> European Ecocycles Society, HUNGARY

<sup>3</sup> University of Debrecen, HUNGARY

<sup>4</sup> University of Gothenburg, Dept. of Conservation, SWEDEN

The widespread use of online bibliographic and citation databases has brought new analytical opportunities in scientific research: it has made it possible to analyse large amounts of literature from many different bibliometric and scientometric aspects. In the last decades, a series of scientific publications have appeared that significantly extend and deepen the analysis of the development and scientific contribution of a given discipline or research topic. The analyses are also useful for presenting the focus, trends, and changes in research topics, and for mapping the disciplinary features and modifications of the field. A preliminary review of the relevant literature shows that no such analysis has yet been carried out in the field of pedology, although there have been recent publications analysing the whole field of soil science from this perspective. Pedology is gaining increasing recognition since the genesis, nature, distribution, environmental significance, the use of soil resources and soil degradation and, consequently, soil conservation and remediation came to the foreground in connection with climate change, global food crisis, water scarcity, increasing urbanisation, and ecosystem deterioration. Thus, pedology requires a transdisciplinary approach including hydrology, climatology, geology, ecology, biology, biotechnology, chemistry, physics, IT, and engineering. Furthermore, social, and economic issues of regenerative sustainability and relevant political challenges must be addressed as well. This is mirrored in the scientific literature of pedology and the closely related transdisciplinary research.

We have performed a biblio- and scientometric analysis of the literature published in the last half century (1983-2023) on pedological research using the Scopus bibliographic and citation database. Our analysis includes an analytical presentation of the relevant literature, such as chronological cross-section, trends, characteristics of literature sources, institutional and author affiliations, volumes, and proportions of literature output in each country and region, thematic diversity of publications, and the organisations that are the most important sponsors of research on this area. By using and combining the keywords in the database, we highlight the inter-, trans-, and multidisciplinary connections in pedological research and their possible changes.

**Keywords:** scientometrics, bibliometrics, soil science, pedology, soil conservation, regenerative sustainability

### GLOMALIN-MEDIATED IMMOBILIZATION OF PB IN SOIL AND SUNFLOWER ROOTS INOCULATED WITH RHIZOPHAGUS IRREGULARIS

N. ALIASGHARZAD, A.H. DANESHFAR, S. OUSTAN

Department of Soil Science, Faculty of Agriculture, University of Tabriz, 5166616471, Iran, TABRIZ, IRAN, ISLAMIC REP

Glomalin as a specific glycoprotein is produced by the fungi belong to the Glomerales in the phylum Glomeromycota. There are evidences indicating that glomalin plays a major role in immobilization of potentially toxic elements (PTEs) in soils by making them less available to the plant roots. In this study, seeds of sunflower (*Helianthus annuus* L. cv. Farrokh Hybrid) were grown in pots containing sterilized soil and inoculated with mycorrhizal fungus, *Rhizophagus irregularis*. Three levels of Pb including 0, 500 and 1000 mg Pb per kg soil (Pb0, Pb1 and Pb2, respectively) as lead nitrate were added to the soil. The results showed that root colonization by mycorrhizal fungi causes a significant increase in the total glomalin of soil (TGS) and root (TGR). With increasing soil Pb level, the amounts of TGS and TGR were significantly declined. Compared to the zero addition of lead, the TGS was decreased by 23.26 and 33.37%, and that of TGR by 28.91 and 38.77% at Pb1 and Pb2 levels, respectively. With increasing levels of Pb, root colonization declined. The Pb translocation factor and shoot Pb concentration of mycorrhizal plants were significantly lower than that of non-mycorrhizal ones. The amounts of Pb immobilized by TGS at Pb1 and Pb2 levels were respectively 3.433 and 4.755 mg g<sup>-1</sup> in mycorrhizal and 2.984 and 3.983 mg g<sup>-1</sup> in non-mycorrhizal plants. Accordingly, Pb immobilized by TGR at Pb1 and Pb2 levels were 4.034 and 4.614 mg g<sup>-1</sup> in mycorrhizal roots, respectively. Non-mycorrhizal roots had no glomalin.

### EFFECTS OF ORGANIC PHOSPHORUS SUPPLY ON BIOLOGICAL NITROGEN FIXATION CAPACITY BY LEGUMINOUS COVER CROPS

D. SAID-PULLICINO<sup>1</sup>, R. LIZCANO TOLEDO<sup>2</sup>, C. LERDA<sup>1</sup>, M. MARTIN<sup>1</sup>, F. FORNASIER<sup>3</sup>, L. CELI<sup>1</sup>

<sup>1</sup> University of Torino, Dept. of Agricultural, Forest and Food Sciences, Grugliasco, ITALY

<sup>2</sup> Universidad del Tolima, Tolima, COLOMBIA

<sup>3</sup> CREA, Centro di Ricerca Viticoltura ed Enologia, Gorizia, ITALY

Legume cover crops are often included in agricultural rotations for enhancing soil nitrogen (N) availability and improving the productivity and sustainability of succeeding crops under low-input systems. Phosphorus (P) is a limiting nutrient in many agro-ecosystems and, apart from affecting plant growth, can also limit biological nitrogen fixation (BNF) by leguminous plants. Thus, increasing P supply can have a positive effect on BNF particularly in P-deficient soils. Whereas the effects of inorganic P (Pi) availability on the mechanisms controlling P acquisition and implications on BNF rates under low P supply are well known, there still remains a lack of evidence on role of organic P (Po) sources in controlling BNF in leguminous plants.

Rhizobia-inoculated hairy vetch (*Vicia villosa* Roth), widely adopted as a legume cover crop, was grown pots containing a P-poor agricultural soil amended with two levels of added P (40 and 120 mg/kg) in the form of Pi (orthophosphate) and Po (phytic acid), and an unfertilized control. We tested the hypothesis that increasing Po inputs can partially alleviate the P limitation effects on BNF because of the ability of leguminous plants to access organic P sources.

When compared to P-deficient conditions (Olsen P < 3 mg/kg) where BNF was primarily limited by plant growth rather than directly due to the high P costs of symbiotic N fixation, Pi addition substantially enhanced plant growth, nodule formation, P acquisition, and BNF efficiency. In contrast, even with the addition of the highest dose of Po, the increase in plant growth, nodule formation, P acquisition, and BNF capacity was much less expressed, indicating that hairy vetch could only minimally access Po sources over the growth period in order to alleviate the P limitation effect on BNF in under P-deficient conditions. These findings suggest that hairy vetch will not be able to provide sufficient BNF for improving soil N inputs in low-fertility cropping systems that rely on organic inputs.

### MEDIOUNA'S LANDFILL LEACHATE (CASABLANCA, MOROCCO): ECOTOXICITY ON SOIL AND STIMULANT EFFECTS ON MEDICAGO SATIVA GROWTH

L. BELASRI<sup>1</sup>, S. SABRI<sup>1-2</sup>, F. HMIMID<sup>1</sup>, S. AIT BENICHOUS<sup>1</sup>

<sup>1</sup> Ain Chock Science Faculty, Hassan II University, Casablanca, MOROCCO

<sup>2</sup> El Jadida Science Faculty, Chouaib Doukkali University, El jadida, MOROCCO

The main landfill in Casablanca, situated in the municipality of Mediouna approximately 20 km from the economic capital, played a significant role in waste disposal from 1986 to 2022. Receiving 5,000 tons of municipal waste daily, it produced over 800,000 m<sup>3</sup>/year of leachate, posing environmental risks as it is collected in an evaporation pond.

While the conventional assessment of leachate involves chemical analyses for identifying pollutants, our investigation delves into its interactions with the ecosystem. In addition to traditional chemical analysis, phytotoxicity tests have been utilized to assess the impact of contaminants, offering valuable insights into their bioavailability and potential effects on soil contamination and plant life.

This study, conducted at the Hassan II University in Casablanca, explores heavy metal accumulation, including Pb, Cd, and Hg, in soil irrigated with varied leachate concentrations. Open-field cultivation of *Medicago sativa* plants involved pre-experiment soil analysis for fertility and granulometric compositions. Post-experiment analysis revealed elevated concentrations of Pb, Cd, and Hg in both plants and soil with increased leachate concentrations.

The results reveal increasing concentrations of Pb, Cd, and Hg in both plants and soil with higher leachate concentrations. For Pb in plants, concentrations ranged from 0.32 ppm (Control) to 7.05 ppm (15%). Similarly, Cd concentrations increased from <0.02 ppm (Control) to 0.08 ppm (15%), and Hg concentrations varied from <0.02 ppm (Control) to 0.03 ppm (15%). Soil Pb concentrations ranged from 0.19 ppm (Control) to 6.56 ppm (15%), Cd concentrations increased from <0.02 ppm (Control) to 0.38 ppm (15%), and Hg concentrations ranged from <0.02 ppm (Control) to 0.079 ppm (15%). Bioconcentration factor (BCF) were calculated to assess heavy metal uptake efficiency by *Medicago sativa* plants.

In summary, the study highlights leachate irrigation's potential impact on heavy metal accumulation, necessitating monitoring and mitigation in agricultural practices. In conclusion, vigilant monitoring and effective mitigation strategies are essential to address leachate irrigation's potential impacts on heavy metal accumulation in soil and plants.

**DOSE AND INCUBATION TIME: EVALUATION OF THE IMPACT OF nZVI NANOPARTICLES ON SELENIUM FRACTION IN ANDISOL SOILS.**

I. FUENTEALBA CORTÉS, K. MANQUIÁN CERDA, N. ARANCIBIA MIRANDA

Universidad de Santiago de Chile, Departamento de Química de los Materiales, Santiago, CHILE

The increased presence of anthropogenic nanoparticles (ENPs) in agricultural soils is due to their extensive use in various daily consumption products (1). Among the most commonly used ENPs are zerovalent iron nanoparticles (nZVI). Due to their high reactivity, these nanoparticles use various stabilization mechanisms, such as sorption, redox processes and precipitation of different analytes, which can generate imbalances in this matrix (2). Volcanic soils have an inorganic fraction and reactive organic matter, conditioning the availability of nutrients, which the presence of nZVI could increase. An example is selenium (Se), which is found in soils as selenite and selenate, chemical forms that tend to be retained in the inorganic and organic part of this matrix so that nZVI can modulate the availability of selenium, altering its bioavailability and a consequence, the nutritional quality of crops.

This study evaluated an A horizon of an Andisol soil (Santa Barbara) incubated with two doses of nZVI nanoparticles (0.5 and 1 mg/kg soil) for three months. Subsequently, Se fractionation was performed using the method described by Sposito et al to determine the impact of dose and incubation time on soil fractions. Our results indicate that the main factor in the change of Se forms was incubation above the nZVI dose. Some 66% of Se is associated with the most labile fractions, 17.4% with the organic fraction, 12% with the carbonate fraction, and only 4.6% with the residual fraction.

The addition of nZVI and subsequent incubation generated a shift from the labile and organic forms to the residual fraction, with a 2.5-fold increase in this fraction compared to the control soil, probably associated with those fractions where nZVI is established. In general terms, the carbonate fraction did not show significant differences in the study.

**Keywords:** nanoparticles, volcanic soils, soil fractionation

### NITROGEN FERTILISATION AND DEFOLIATION EFFECTS ON THE CONTRIBUTION OF RHIZODEPOSITION INTO THE FORMATION OF PARTICULATE AND MINERAL-ASSOCIATED ORGANIC MATTER

B. BICHARANLOO, F. DIJKSTRA, C. WARREN, B. SINGH

Sydney Institute of Agriculture, School of Life and Environmental Sciences, The University of Sydney, Sydney, AUSTRALIA

Soil organic matter (SOM) is a crucial component for storing organic carbon (C) in terrestrial ecosystems, and thereby mitigating global climate change. The substantial release of organic compounds from living roots (rhizodeposition) is gaining recognition for its pivotal role in forming SOM pools. Rhizodeposition enhances microbial biomass with faster turnover rates, influencing SOM formation and decomposition. Rhizodeposition can be transformed into particulate organic matter (POM), but can also be stabilised into mineral-associated organic matter (MAOM) through direct adsorption onto soil minerals or via microbial necromass. This dual transformation highlights the critical role of rhizodeposition in mitigating climate change. This study aimed to examine how rhizodeposition contributed to POM and MAOM formation in a grassland affected by long-term application of nitrogen (N) fertilisation (0 vs. 40 kg N ha<sup>-1</sup> yr<sup>-1</sup>) and defoliation frequency (3-4 vs. 6-8 clipping events year<sup>-1</sup>), and to what degree rhizodeposition was incorporated into microbial biomass. A <sup>13</sup>C<sub>2</sub>O<sub>2</sub> pulse labelling technique was conducted at field condition over two different seasons to assess rhizodeposition and to examine the incorporation of recently produced rhizodeposition into microbial biomass, POM and MAOM fractions and the contribution of microbial necromass in the formation of POM and MAOM. Preliminary results showed that rhizodeposition increased with N fertilisation at low defoliation but decreased with increased defoliation frequency. The incorporation of rhizodeposition into microbial biomass decreased with N fertilisation but was not affected by defoliation frequency. At the time of writing, we are still waiting for results on <sup>13</sup>C and necromass measurements in POM and MAOM fractions, but these preliminary results could suggest that rhizodeposition contributed to SOM formation more strongly via direct adsorption to soil minerals than via necromass of microbially-processed rhizodeposition. Our results should provide insightful information regarding the stabilisation of rhizodeposition into SOM pools under different grassland management practices.

### ABOVE AND BELOW GROUND LACTOBACILLUS IN OLIVE ORCHARDS PLACED IN DIFFERENT SOIL FORMATIONS IN TUSCANY

M.T. CECCHERINI<sup>1</sup>, S. PELACANI<sup>2</sup>, A. ROCCOTELLI<sup>1</sup>

<sup>1</sup> Dep. of Agriculture, Food, Environment and Forestry (DAGRI), University of Florence, Florence, ITALY

<sup>2</sup> Dep. of Earth Science (DST), University of Florence, Florence, ITALY

<sup>3</sup> Dep. of Agriculture, Food, Environment and Forestry (DAGRI), University of Florence, Florence, ITALY

Lactic Acid Bacteria (LAB) and their prebiotic substances produce beneficial effects not only in the animal gastrointestinal tract, but also in rhizosphere soil of many plants, including olive trees. LAB in soil have the action to control pathogenic bacteria and, coming from the soil through xylem sap in olive leaves, fruits and oil they are responsible of the hydrolysis of Oleuropein, the bitter-tasting secoiridoid glucoside. Moreover, it has been shown that the diversity of LAB populations in olive fruit was dependent on the olive cultivar and the geographical origin.

In this preliminary study we investigated whether *Lactobacillus* spp. were present in different amount i) in soil, leaves and drupes of centenary olive trees of the same olive grove and ii) in olive groves located in soil with different lithological origins. This analysis was performed by quantitative PCR using the *rpoB* gene as it is considered significantly powerful in identifying the genus *Lactobacillus* and present in one copy per genome.

A first result is that the amount of lactobacilli decreases from the soil to the leaves and from the leaves to the drupes by approximately 1 order of magnitude, as was expected to be found.

To explore the differences between *Lactobacillus* amount across contrasting lithological substrate, hence the variation in *Lactobacillus* quantity across soil, olive cultivars and climatic zone was visualized and assessed with non-metric multi-dimensional scaling (nMDS) ordination plot of Bray-Curtis. The results of the ordinary plot showed a significant spatial autocorrelation between samples collected in the lithologies characterized by limestone pebble/gravel soil. Furthermore, the *Lactobacillus* amount differed between olive cultivars.

This is only a first approach to understanding the involvement of the *Lactobacillus* population in the olive grove ecology.

### CASING SOIL AS A POSSIBLE SOURCE OF GREEN MOLD CONTAMINATION IN CHAMPIGNON CULTIVATION

L. SASIC ZORIC, L. JANJUSEVIC, M. DJISALOV, A. SIMEON, S. BRDAR, T. KNEZIC, I. GADJANSKI

University of Novi Sad, BioSense Institute, Novi Sad, SERBIA

Green mold disease, caused by *Trichoderma* spp., is the most harmful disease for edible mushroom production, such as champignons. The disease affects yield, fruit body formation, and can be spread through contaminated tools, substrate, clothing, air and insect vectors. Considering the significant degree of yield loss in mushroom production due to the appearance of the mentioned disease, the need for early, rapid and specific detection of the presence of *Trichoderma* spp. in casing soil is exceptional. In this study, we aimed to examine casing soil as a possible source of *Trichoderma* contamination, as well as to develop a novel point-of-need assay for its early screening. The casing soil samples were collected in two-time points: before applying on cultivation bags (three samples) and seven days after applications (ten samples). The samples were used for microbiological analysis using cultivation methods, as well as molecular biology analysis using the DNA metabarcoding approach and loop-mediated isothermal amplification method (LAMP). *Trichoderma* is cultivated from eight casing soil samples. Genomic DNA extracted from a pure *Trichoderma* culture was used for development of LAMP assay that is evaluated using eDNA from casing soil samples. In addition to valuable information of the diversity of casing soil fungal community, results of DNA metabarcoding confirmed the presence of *Trichoderma* spp. in one sample taken before, and four samples taken after application of casing soil on cultivation bags. Our results confirm that casing soil is a source of *Trichoderma* spp. infestation in champignon production, although there are likely multiple sources. The DNA metabarcoding approach was useful for fungal diversity studies, but limited in detecting *Trichoderma* spp. On the other hand, the developed point-of-need LAMP assay showed high sensitivity in early screening for *Trichoderma*, although its efficiency is highly dependent on the representativeness of the sample being analyzed.

### THE EFFECT OF LIVESTOCK- AND UNGULATE-MADE GEODIVERSITY OF SOIL FUNGAL COMMUNITY IN DRYLANDS

Y. STEINBERGER<sup>1</sup>, I. STAVI

<sup>1</sup> Faculty of Live Sciences Bar Ilan University, Ramat Gan, ISRAEL

<sup>2</sup> ADSSC, Arava, ISRAEL

Changes in soil compaction and soil-water conditions are expected to shape the spatio-temporal patterns of soil biotic biomass and processes, and specifically, the soil biota composition and diversity. Our study aims to comprehensively investigate how livestock and wild ungulate activity impacts soil fungal communities in dryland geo-ecosystems. By assessing fungal community composition, diversity, and functionality at the phylum and order levels, we hope to gain insights into this aspect of ecosystem functioning. Therefore, the study's major objective is to assess the effect of livestock- and wild ungulate-made trampling routes on drylands' soil fungal community, at the phylum and order levels. We will examine three regions along an aridity gradient comprising of a semi-arid, an arid, and a hyper arid site; two opposing hillslope aspects composing of a north- and south-facing hillsides; and three microhabitats consisting of shrubby patches, intershrub spaces, and animal trampling routes. The study hypothesizes that soil fungal community's phyla and orders will be regulated by livestock- and wild ungulate-made trampling routes. Specifically, it is hypothesized that soil fungal community's phyla and orders that are characterized with relatively high durability to dryness conditions are most abundant in the driest region and least abundant in the moistest region, more abundant in southern aspects than in northern aspects, and most abundant in the trampling routes and least abundant in the shrubby patches. Preliminary results had demonstrated the importance of perennial shrubs' rhizosphere as a hub for fungal diversity, where the main phyla are Ascomycota, Basidiomycota, and Chytridiomycota. Hillslope aspect was found to affect the fungi community composition as and functionality. This study will contribute to the understanding of the impact of grazing and trampling on soil fungal communities and ecosystem functioning under climatic change scenarios.

### ADAPTATION OF DIAGNOSTICS AND SOIL TAXONOMY OF UKRAINIAN SOILS TO THE WRB

V. SOLOVEY, V. LEBED

NSC ISSAR named after O.N. Sokolovsky, Soil Resources Department, Kharkiv, UKRAINE

International communication of soil scientists from different countries determines the need to adapt the national nomenclature of soils to WRB. The experience of direct correlation of classification is negative due to the mismatch of their principles, differentiation on taxonomic levels due to differences in classification structures. However, both international and national classification of soils have a substantive nature of diagnosis based on morphological features and property parameters. This determines the theoretical possibility of adapting the name of soils of Ukraine to WRB through the comparison of diagnostic features and property parameters. At different times, there have been successful attempts to adapt the names of soils of the national classification to the WRB.

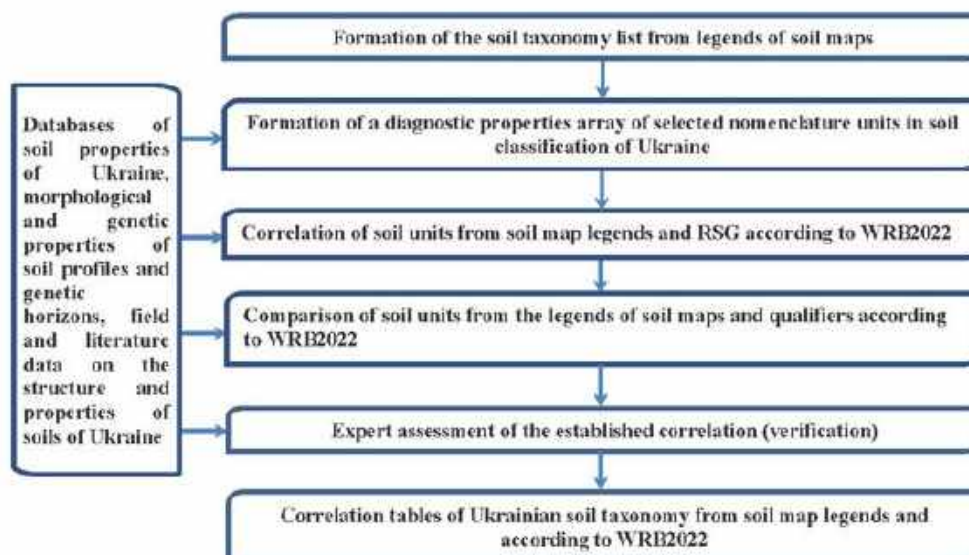

To determine the soils of Ukraine, 20 main diagnostic indicators are used, most of which correspond to the WRB system. To date, relative diagnostic coefficients of the genetic status of soils have been developed, which can be used as pedotransfer models to calculate certain soil properties in different parts of the profile according to WRB diagnostic depths.

Adaptation of national classification soil names to WRB is performed in the following sequence: 1) A list of national classification soil nomenclature is being formed; 2) A set of diagnostic properties and analytical characteristics is defined for each soil according to WRB; 3) Determination of the soil's belonging to the Reference Soil Group is carried out according to the defining key based on the profile morphology and the parameters of diagnostic properties; 4) The search for principal and supplementary qualifiers is carried out by comparing soil properties with WRB diagnostic criteria.

The source of information for establishing diagnostically significant soil properties is the diagnostic criteria of the national soil classification of Ukraine, the data of the Ukrainian soil information center, the results of experimental studies, etc.

The presented soil taxonomy adaptation algorithm was tested for the legends of soil maps of Ukraine at the scale of 1:750,000 and 1:200,000.

№	Soil diagnostic criteria
1	Humus (organic carbon) content
2	Cation exchange capacity
3	Base saturation
4	Content of exchangeable cations of calcium, magnesium, sodium and potassium
5	pH <sub>H2O</sub>
6	Content of the "skeleton" (coarse fragments)
7	The depth of the humus profile
8	Deep of carbonates effervescence (under 10 % HCl)
9	Presence or absence of textured profile differentiation
10	Presence or absence of gleying signs
11	Localization depth of gleying signs
12	Total concentration of soluble salts
13	Granulometric composition, texture
14	Presence or absence of eluvial horizon enriched with silica
15	Presence or absence of a peat layer
16	Presence or absence of black, chestnut or brown tint in the upper horizon
17	Presence or absence of white-eye
18	Coefficient of relative humus accumulation
19	Coefficient of profile humus accumulation
20	Coefficient of organoprofile regression

Since 2016, members of the French Soil Science Society (AFES) have been supporting teachers and trainers keen to enrich and consolidate their teaching on soils, through the PromoSolsEduc network (Promoting Soils in Education). Exchanges with this network of around a hundred people from general and specialized education, as well as partnership work “RMT Sols et Territoires” and “ADEME”, have contributed to the emergence of three interconnected projects aimed at integrating soil knowledge into all levels of education :

1. To facilitate exchanges of experiences between teachers and trainers, a collection of the experiences of thirty teachers and trainers entitled '24 teaching sequences for teaching soil' will be published in 2024 by EDUCAGRI editions. The book will be supported by a WEB interface to complement the teaching sequences, a dynamic map of teachers and trainers, and access to a center of documentary resources on soils.

2. Teachers' need for fun tools to engage learners on the full range of soil issues prompted ADEME to work with AFES on the design of the Fresque du Sol serious game. The game (In-class or online) was officially launched in May 2023. It already has over 4,000 players and almost 130 networked animators, progressively acquiring cross-disciplinary skills on soils. It has already been tested in various technical and general education contexts, and is currently being translated into English, Spanish and Chinese.

3. Today, it is crucial to train as many people as possible to understand and interpret soil observations in the field. We have initiated the structuring of a network of committed soil pit referents able to support teachers and trainers in understanding soil in the field. A survey has identified 45 soil pit referents. A dynamic map will enable them to be identified and contacted via the AFES website. This network of soil field referents will be closely linked to the network of participants in participatory soil science and research projects, run by AFES.

The generational gap in the study of soil science in Mexico and Latin America, and the lack of interest of the new generations have urged the implementation of contests as an innovative strategy to attract young people to this area. The Mexican soil judging contests emerged in 2018 as a formative activity where young people implement their skills to describe, classify, and determine the potential use of soils. They also seek to encourage networking of students with researchers and distinguished institutions at a national level. In the five editions held, the participation of students and young researchers from the Mexican Society of Soil Science youth group in organizing the events has been outstanding. There have been 3 face-to-face editions (2018, 2019 and 2023) and 2 virtual editions (2020 and 2021), where 693 undergraduate and 272 graduate students have participated, reaching even abroad. The increase of participants through the editions is mainly the result of promotion in social media with dissemination materials (v.g. edaphographies project) and the offering of a preparation course prior to the competition. These competitions have proven to be motivating activities for the study of soil science in different regions throughout the country, allowing academic projection for the participants at a national level, and motivating the participation of Mexican teams in international soil judging contests.

### CHARACTERIZATION OF LITTERS AND SOILS IN AN ITALIAN MOUNTAIN AREA BY A CHEMICAL, BIOLOGICAL AND SPECTROSCOPICAL APPROACH

F. TAMBONE <sup>1</sup>, P. BECCARELLI <sup>1</sup>, L. BRENO <sup>1</sup>, M. ZUCCOLO <sup>2</sup>, G. BORGONOVO <sup>3</sup>, S. MAZZINI <sup>3</sup>, B. SCAGLIA <sup>1</sup>

<sup>2</sup> Centre of Applied Studies for the Sustainable Management and Protection of Mountain Areas, University of Milan, Brescia, ITALY

<sup>3</sup> Department of Food, Environmental and Nutritional Sciences, University of Milan, Milan, ITALY

Natural soils provide a wide range of goods and services but, despite this, deforestation and forest degradation continue at an alarming rate. According to the FAO in the last 25 years, there has been a net loss of 5.2 million ha/year. In Italy, however, the forest area has increased from 5.6 million to 11.1 million ha due to the abandonment of marginal agricultural areas. Soil respiration represents from 60 to 90% of the total respiration of the forest ecosystem influencing the atmospheric CO<sub>2</sub> balance. In this context, a study was conducted in Valle Camonica (North Italy) with the aim of evaluating the accumulation of carbon in soils and litter with different plant cover (chestnut, beech, pine). Chemical, respirometric and spectroscopic characteristics of the labile (soluble carbon) and recalcitrant (humic-like) carbon of the litter and soil were evaluated. The composition of the total carbon, assessed by <sup>13</sup>C CPMAS NMR, highlighted the abundant presence of starch and cellulose, especially in the litters. Otherwise, aromatic compounds tend to accumulate in the soil (concentration effect). The liquid state <sup>1</sup>H NMR analysis of the soluble and recalcitrant carbon indicates that the labile carbon is rich in low molecular weight compounds. In all soluble carbon fractions, a high percentage of carbohydrates was found, which are more concentrated in the soil layers. The humic-like carbon extracted from soil and litter of beech and chestnut were similar in the NMR profile, while pine showed higher values of aliphatic compounds (resinous) typical of this pine and the aromatic carbon content was lower. The chemical properties were correlated to the respirometric data and the labile carbon had the greatest influence on soil respiration. In conclusion, the study highlighted that vegetal cover can, even in the same climatic context but depending on its composition, influence both soil properties and the rate of mineralization, with consequences both on CO<sub>2</sub> emissions and soil carbon storage.

#### SOIL CONTEXT OR LAND COVER – WHICH FACTOR PLAYS A MORE SIGNIFICANT ROLE IN THE STABILIZATION OF SOIL ORGANIC MATTER STOCKS IN THE GORCE MOUNTAINS (SOUTHERN POLAND)

A. RUDNIK <sup>1</sup>, M. STOLARCZYK <sup>1</sup>, K. BUCZEK <sup>2</sup>, L. MUSIELOK <sup>1</sup>

<sup>1</sup> Jagiellonian University, Faculty of Geography, Institute of Geography and Spatial Management, ul. Gronostajowa 7, Krakow, POLAND

<sup>2</sup> Polish Academy of Sciences, Institute of Nature Conservation, Al. Adama Mickiewicza 33, Krakow, POLAND

One key strategy for mitigating climate change involves capturing carbon dioxide through photosynthesis and sequestering it in the form of belowground organic matter. Mountainous regions play a crucial role in storing organic compounds as soil organic matter (SOM) due to challenging climatic conditions that limit microbial decomposition processes. Mountains are highly susceptible to global changes such as temperature rise and change of land cover, impacting the stability and composition of soil organic matter stocks. The Gorce Mountains in southern Poland serve as a noteworthy example where land abandonment and the effects of global warming have induced substantial transformations in land cover. Additionally, the region's soil cover, typical of mountainous areas, exhibits distinct local variations in soil-forming processes. Consequently, this study aims to assess the influence of different land covers and various soil-forming processes on the SOM stocks and their stability.

Soils under different types of land cover, including ancient forests, successional forests, shrubs, meadows covered with shrub vegetation, and grasslands, and characterized by diverse soil-forming processes (Podzols and Cambisols) were examined concerning the SOM stocks and their stability. Soils under ancient forests and meadows with shrub vegetation exhibited the largest SOM stocks within the top 30 cm of depth, while successional forests had the lowest. However, the stability of SOM was more closely tied to the soil-forming process than the type of land cover. In the surface horizons of both Podzols and Cambisols, the majority of SOM was found in the form of particulate organic matter, representing a relatively unstable fraction. Conversely, the subsoil horizons in Cambisols showed a significantly higher proportion of resistant mineral-associated organic matter compared to Podzols.

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 952327 and has been supported by grants from the Priority Research Area Anthropocene and the Faculty of Geography and Geology under the Strategic Programme Excellence Initiative at Jagiellonian University.

<sup>6</sup> Competence Centre for Plant Health, Free University of Bozen-Bolzano, Bolzano, ITALY

Soil organic matter (SOM) plays a crucial role in the carbon (C) cycle as both a stock and a source of C. Particulate organic matter (POM) and mineral-associated organic matter (MAOM) are two forms of SOM that differ in their cycling rates. POM is fast-cycling and consists of partially decomposed plant and animal material, while MAOM is slow-cycling and composed of microbial bodies and mixed organic compounds. Microorganisms are involved in the decomposition of POM and MAOM, but microbial communities and their activities can differ between these two fractions. Moreover, different environmental conditions can significantly impact microbial communities, influencing the balance between C fractions and atmospheric C concentrations. Therefore, this study aims to compare and understand fractions dynamics and their associated organisms under different environmental conditions.

Samples were collected from two alpine sites at two elevations, with a 5 °C temperature difference: a loamy deposit at 2500 m a.s.l. and a sandy substrate at 1500 m a.s.l. Each sample was physically separated into fractions >63 (POM) and <63 microns (MAOM), and the total DNA was extracted. Preliminary results show that both sites are dominated by POM over MAOM, with POM representing ~60% of each sample. Under a climate change scenario, i.e., increasing soil temperatures, the dominance of POM may indicate higher losses of SOC due to the faster turnover associated with this fraction than in lowland soils typically dominated by MAOM. DNA extractions revealed that most (20-80%) of the DNA was associated with the MAOM fraction, usually characterised by a higher amount of C than POM. However, further analysis (i.e., quantitative PCR on taxonomical markers genes) will be conducted to determine the origin of the DNA associated with each fraction and the total C concentration. The results are expected to deepen the understanding of C fractions dynamics, highlight how these soils respond to environmental changes, and offer new tools to manage and conserve soil carbon stocks in these environments.

The physical fractionation of soils allows the separation of diverse soil organic matter (SOM) pools having various physical and chemical properties to stabilize C. In this study the microbial community composition of SOM fractions were examined.

Topsoil (0–20 cm) and subsoil (30–50 cm) samples were collected from an Arenosol, a Chernozem and two Cambisols from Hungary. Four different SOM fractions – particulate organic matter (POM), macroaggregate-protected (MaA), microaggregate-protected (MiA) and silt- plus clay-sized (s+c) – were separated from the samples following aseptic working rules.

The environmental DNA from the bulk soils and the SOM fractions was extracted with the Qiagen DNeasy PowerSoil Kit. The V3–V4 region of the 16S rRNA gene was used for prokaryotic taxonomic diversity analysis. DNA sequencing was performed on an Illumina MiSeq platform. The mothur v1.43.0 software was used for the procession of sequence reads based on the alignment to the SILVA Release138 SSU NR database.

Results showed, that the composition of bacterial communities was dominated by phyla Actinobacteriota (13%–66%), Firmicutes (6–57%) and Proteobacteria (<33%) (and Acidobacteriota (5–16%) in the Arenosol samples).

The bacterial community composition showed high similarities among the samples derived from the same location. Soil depth and pH was another important parameter affecting the composition of bacterial communities. Although, microbiological differences derived from the different SOM fractions were less prominent, some conclusions can be drawn: 1) the proportion of the phylum Firmicutes showed a slight increase in the MaA, MiA and s+c fractions; 2) the quantity of the previously uncultured Bacillaceae, Pseudoarthrobacter and Massilia was increased in the MaA, MiA and s+c fractions and 3) the POM fractions were the most diverse, whereas the s+c fractions were the least diverse samples according to the Shannon and inverse Simpson indices.

This work was supported by the Eötvös Loránd Research Network [grant No. SA41/2021] and the National Research, Development and Innovation Fund, Hungary [project no. FK 142936].

### THE TEMPERATURE SENSITIVITY OF THE DECOMPOSITION OF ORGANIC MATTER FRACTIONS OF HUNGARIAN SOILS WITH DIFFERENT VEGETATION COVERAGE

T. FILEP<sup>1,2</sup>, D. ZACHÁRY<sup>1,2</sup>, G. JAKAB<sup>1,2,3</sup>, Z. SZALAI<sup>1,2,3</sup>

<sup>1</sup> HUN-REN Research Centre for Astronomy and Earth Sciences, Geographical Institute, Budapest, HUNGARY

Understanding the relationship between environmental changes and rates of the decomposition of soil organic matter is critical for projecting changes in soil carbon fluxes under changing climate conditions. The respiration of terrestrial ecosystems, including microbial decomposition of SOM, would be more sensitive to the global warming than would gross primary productivity, hence, the investigation of the temperature sensitivity of SOM decomposition, commonly referred to as Q<sub>10</sub>, is very important for modelling changes in soil C stock.

To evaluate the temperature effect on the decay of organic matter, SOM fractions (s+c, S+A and POM) of soils from different vegetation coverage were incubated for 1 year at 15, 25 and 35 °C. Total C respired (CO<sub>2</sub>-C) through time up to 365 days was fitted with a first-order kinetic C model and the Q<sub>10</sub> factor was calculated. The main results of the incubation of soil organic matter fractions are the follows:

- The decay constants (k, day<sup>-1</sup>) of the organic C fractions calculated based on the CO<sub>2</sub> evaluation in the soils were the higher in the POM fractions with average k value of 2.0x10<sup>-4</sup> at 15 °C, 4.8x10<sup>-4</sup> 25 °C, 1.8x10<sup>-3</sup> 35 °C.
- Lower k values in forest soils comparing to the grass and arable area, indicating that decomposition is inhibited - this is due to environmental factors (e. g. pH) and lower substrate quality of forests.
- The decomposition rate of all organic matter fractions increased significantly with increasing temperature. This can be clearly seen in the Q<sub>10</sub> factor, which is the response of decomposition rate (k) to temperature (T): 3-3.5 for all fractions, with the exception of oak s+c and arable S+A. For the latter, we obtained values well above the average of 5.4 - presumably the effect of arable cultivation and ploughing, which increasingly degrades the macro- and micro-aggregates of the soil.

This work was supported by the Development and Innovation Fund of Hungary [grant No. NKFIH 132191].

#### IMPACT OF BIOCHAR APPLICATION ON SOIL MICROBIAL RESPIRATION UNDER SIMULATED CLIMATE CHANGE WITHIN A MEDITERRANEAN CROPLAND

M.J. CARPIO ESPINOSA <sup>1</sup>, C. BONNEFOY-CLAUDET <sup>2</sup>, M. THEVENOT <sup>2</sup>, O. MATHIEU <sup>2</sup>, I. BENAVENTE <sup>1</sup>, J.C. GARCÍA-GIL <sup>1</sup>, C. PLAZA <sup>1</sup>, M. PANETTIERI <sup>1</sup>

<sup>1</sup> Instituto de Ciencias Agrarias, Consejo Superior de Investigaciones Científicas, Madrid, SPAIN

<sup>2</sup> Biogéosciences, UMR 6282 CNRS, Université Bourgogne Franche-Comté, Dijon, FRANCE

The application of biochar has emerged as a potential climate change mitigation strategy in agriculture; however, we still need to better understand the soil microbial responses to the joint effects of climate change and biochar in Mediterranean croplands. To fill this knowledge gap, we evaluated the effects of cumulative biochar application (20 t ha<sup>-1</sup> yr<sup>-1</sup>) under climate change conditions in a long-term field experiment conducted in semiarid agricultural soil in Central Spain. Rainout shelters and open-top chambers were set up to simulate a 30% rainfall reduction combined with an increase of 2°C in soil temperature. The experimental treatments included unamended control soil (C), soil amended with biochar (B), unamended control soil with rainfall reduction and warming (Crr+w), and soil amended with biochar with rainfall reduction and warming (Brr+w). A series of soil incubations were set to a range of 5-35 °C for CO<sub>2</sub> measurements, which were addressed using the fully automated system Respicond respirometer X. Results revealed that both Brr+w and Crr+w treatments exhibited higher soil respiration rates compared to B and C treatments across all temperature ranges. However, the application of biochar did not alter the temperature sensitivity of soil carbon mineralization, as evidenced by the absence of significant differences in Q<sub>10</sub> values among the treatments. This study illustrates how the interactions between biochar amendment and future climate change scenarios influence microbial communities and its role in the global C turnover within a Mediterranean agroecosystem.

### DESTABILISATION OF ORGANIC CARBON IN MOUNTAIN SOILS AS A RESULT OF GLOBAL WARMING

N. BONFANTI, J. POULENARD, J.C. CLEMENT

Savoie Mont Blanc University, EDYTEM lab, CARRETEL lab, CHAMBÉRY, FRANCE

Stocks of organic carbon in mountain soils are known to be higher and more vulnerable than in lowland soils. Low temperatures in these environments tend to limit the SOC decomposition and mineralisation, leading to an increase in its residence time and its accumulation. In the context of global warming, we can expect that the environmental carbon stabilisation due to low temperature as found in alpine soils will be reduced, resulting in a positive feedback loop from global warming (increase in temperature -> environmental SOC destabilisation -> CO<sub>2</sub> release -> increase in the greenhouse effect -> increase in temperature etc...). On the other hand, global warming may favour net primary productivity, leading to an increase in SOC inputs and thus to a negative feedback loop. The relative increase in these mineralisation vs. productivity determines the behaviour of alpine soils either as a carbon source or sink. To test this hypothesis, the "Alpages Volants" experiment involved transplanting soils from the alpine (2500 m a.s.l.) to the subalpine stage (1900 m a.s.l.), simulating a global climate warming of app. +3°C. Soil organic carbon fluxes and stocks were estimated based on respiration and carbon gas exchange (NEE) and on soil sampling seven years after transplantation to measure SOC quantity and stability using various methods (RockEval, fractionation, chemical characterisation, mean residence time). Preliminary results show a reduction in the quantity of SOC in warmed soils. This lost carbon mainly occurs as labile forms (thermally labile, WEOC, POxC) supporting the hypothesis of the potential 'carbon source' behaviour of alpine ecosystems with global warming.

#### THE IMPACT OF MICROBIAL-MEDIATED PLANT HUMIFICATION PRODUCTS ON SOIL ORGANIC MATTER TRANSFORMATION

Y. ZHANG

State Key Laboratory of Black Soils Conservation and Utilization, Northeast Institute of Geography and Agroecology, Changchun, CHINA

Microbial-mediated input of plant residues and their humification products plays a key role in the transformation and sequestration of soil organic matter. This study aims to utilize  $^{13}\text{C}^{15}\text{N}$  double labeling tracing technology in incubation experiments to quantify the differences in the fate and distribution contribution of the C and N of plant humification products under the mediation of different exogenous microorganisms in soil organic matter (SOM) and dissolved organic matter (DOM). The exogenous microorganisms employed include *Trichoderma reesei*, *Trichoderma harzianum*, *Phanerochaete chrysosporium*, and *Bacillus subtilis*. Additionally, a combination microbial treatment comprised of *Trichoderma harzianum*, *Phanerochaete chrysosporium*, and *Bacillus subtilis* was also employed. The study also aims to reveal the variation patterns of soil active organic carbon and humic carbon components in response to different exogenous microorganisms. The key conclusions of the study are:

Fungal-mediated humification products significantly improved translational immobilization in soil compared to bacterial and control groups, and the fungal treatments contributed more to DOM and stimulated soil-derived dissolved nitrogen. *Trichoderma reesei* treatment was the most effective in immobilizing the carbon and nitrogen derived from humification products.

Fungal-mediated humification products outperformed bacterial mediation in enhancing labile organic carbon and humic acid fractions. The treatment with *Trichoderma reesei* was the most effective in increasing contents of easily oxidizable organic carbon, microbial biomass carbon, and humic acid carbon. Moreover, the combination microbial treatments significantly increased fulvic acid carbon and substantially reduced humification degree in the early part of the experiment, but the three fungal treatments were effective in increasing fulvic acid carbon in the later part of the experiment.

In summary, these findings provide a theoretical basis for identifying suitable microbial regulation measures for farmland management to improve SOM transformation and humification effects. These conclusions also offer practical guidance for agricultural production and soil carbon sequestration and fertilization.

The local pedodiversity in semi-arid tropical climate is controlled by a number of interacting factors, whose contribution to the final form of individual soil characteristics is often difficult to discern. The present study focuses on a detailed description of five different soil profiles located in the flat foothills of the Otavi Mountains, northern Namibia. A multi-proxy approach consisting of analyses of clay mineralogy, micromorphology and geochemical parameters was used to disentangle the drivers of an extraordinary local soil diversity and to identify the patterns of recent and relict pedogenesis. Significant differences in profile stratigraphy were observed in the soils studied, represented by weathered Chromic and Haplic Luvisols and humus-rich soils with mollic epipedons (Haplic Phaeozem, Calcic Kastanozem) and vertic features (Haplic Vertisol). Complex lithology, represented by in-situ weathered rocks, mainly shales and dolomites, and younger unconsolidated sediments of various origin, duration of pedogenesis and subtle changes in local topography were identified as the main factors for the sharp transitions between the patches of each soil group, while a direct effect of different management on the spatial distribution of soil classes could not be demonstrated. The soils studied differed significantly in the proportions of clay minerals and iron forms, with more advanced phases of in-situ weathering typically expressed by an increased ratio of kaolinite and crystalline iron forms, whereas younger humus-rich soils were more strongly represented by phyllosilicates with a higher proportion of smectite. The development of vertic features was mainly conditioned by the localisation of the profile in a minor local depression with prolonged water stagnation and abundance of the finest clay fraction. The dynamics of landscape processes in the area is evidenced by an important admixture of colluvial and fluvial material in the profiles, often bearing pedofeatures inherited from previous pedogenesis. Formation of the mollic horizons was probably enhanced by the admixture of aeolian loess-like material.

The study was supported by grant no. 23-05051S of the Czech Science Foundation.

The active microbiome is the sole microbial driver of the main biogeochemical processes, which is only a tiny portion of the total microbiome. Therefore, the lack of accurately distinguishing active microbiomes and exploring the driving mechanisms on a large scale might mistakenly estimate the role microbiomes play under climate change. Here, we report the results using soils from 601 sites across four ecosystems (forest, grassland, cropland, and desert) in China. We determined the proportion of active microbiome by CTC (5-cyano-2,3-ditolyltetrazolium chloride by flow cytometry). We demonstrate that the proportion of soil active microbiome is 1.55% (ranging from 0.02% to 19.63%) in China, which was increased along the latitude. The highest proportion of active microbiome was showed in forest, and the croplands exhibited the lowest proportion of active microbiome even without significant difference with desert. Sufficient available nutrients (nitrogen and phosphorus) directly extended the proportion of active microbiome, which might be positively driven by climate change (precipitation and the minimum annual mean temperature). These findings imply that the soil original nutrient availability would affect the tiny but functional active microbiome under climate change. This underscores the importance of isolating the active component in soil microbiome–climate feedback assessments. Quantitative differentiation of active biomass offers a more accurate evaluation of ecologically relevant microorganisms actively contributing to ecosystem functions.

### HUMAN IMPACT ON SOIL DEVELOPMENT IN THE COASTAL PLAINS OF POLAND

P. HULISZ<sup>1</sup>, S. ROZANSKI<sup>2</sup>, A. MICHALSKI<sup>3</sup>, M. DABROWSKI<sup>4</sup>

<sup>1</sup> Faculty of Earth Sciences and Spatial Management, Nicolaus Copernicus University in Torun, Torun, POLAND

<sup>2</sup> Faculty of Animal Breeding and Biology, Bydgoszcz University of Science and Technology, Bydgoszcz, POLAND

<sup>3</sup> Faculty of Earth Sciences and Spatial Management, Nicolaus Copernicus University in Torun, Torun, POLAND

<sup>4</sup> Faculty of Earth Sciences and Spatial Management, Nicolaus Copernicus University in Torun, Torun, POLAND

The main cause of anthropogenic changes in the environment along the coast of the southern Baltic Sea in Poland was hydrotechnical and regulatory works initiated already at the end of the 19th century and carried out on a large scale, e.g. construction of river channels, polders, flood banks, breakwaters, and melioration network. In this study, we analyzed 66 soil profiles from studies carried out in the years 2010-2022, representing coastal soils formed on marine and marine-riverine sediments in the following locations: Szczecin Lagoon (the reverse delta of the Swina River), Kamien Lagoon, Puck Lagoon, Vistula River delta (including its artificial mouth - Przekop). It was demonstrated that anthropogenic changes in local environmental conditions in the Baltic coastal zone caused contributed to the formation of soils with specific morphology and properties. The most important effects of direct or indirect human impact included:

- changes in direction, rate and type of sedimentation - growth of new land with alluvial soils,
- a significant increase in the heterogeneity of soil properties in vertical (multi-stratified soils) and horizontal gradients, reflecting the high dynamics of the local depositional environments,
- development of the technogenic soils made of human-altered and human-transported materials,
- occurrence of polygenetic soils,
- soil paludization together with an increase of soil salinity within polders and alluvial islands, resulting in the succession of unique and protected halophilic vegetation,
- loss of organic soils in the meliorated areas,
- the potential risk of release of potentially toxic elements into the environment due to the formation of acid sulfate soils.

The results showed that the spatial pattern of the coastal soils is more complex than indicated by the available cartographic material. The data obtained may be useful in the management of coastal areas, much of which is under protection.

### FIELD SCALE SOIL VARIABILITY AND ITS DIAGNOSTIC DESCRIPTION SUPPORTING PRECISION FARMING

E.Z. DOBOS<sup>1</sup>, E. MICHELI<sup>2</sup>, K. KOVÁCS<sup>1</sup>, M. RAJHI<sup>1</sup>, T. BEREKET<sup>1</sup>, A. DOBAI<sup>1</sup>, T. DEÁK<sup>1</sup>

<sup>1</sup> University of Miskolc, Miskolc, HUNGARY

<sup>2</sup> Hungarian University of Agriculture and Life Sciences, Godollo, HUNGARY

Field scale soil and terrain variability responsible for yield variation is not provided by the existing soil maps. This study aims to demonstrate the feasibility and inevitable nature of the field mapping to provide the data and interpreted soil information for the interpretation of biomass variation and the identification of the treatment necessary to handle the variability. A traditional approach of using remotely sensed information, high resolution terrain data and geomorphology together with field soil profile characterization, sampling and lab analysis to understand the horizontal and vertical variability of the field was used to develop a spatial soil description model capable of explaining the within field variability. This information complemented with the current surface crop conditions and the crop performance can be used to understand the acting processes and select adequate treatments for appropriate management. The soil variability is explained by WRB diagnostics. The aim was to test the diagnostic approach to explain the existing variability and test its capability to describe the differences and drive the soil management and agrotechnological approaches.

Several heterogeneous agricultural parcels have been selected for the study with different soil types and soil forming conditions. Approximately 100 Soil profiles have been opened with the depths of 100 to 150 cm. All of these profiles have been described in the field and all soil morphological features have been recorded and interpreted. Profiles have been sampled by genetic horizons and chemical and particle size analysis have been performed. Lab data and morphological characterization were interpreted together to understand and identify the soil unit and their spatial extension.

It was concluded, that WRB diagnostics can be used to describe the differences between the management zones. However, the less variable fields often have significant, but small differences between the different units, which stays within one diagnostic class. Therefore the diagnostic description does not differ, but these small differences are still need to be expressed in the management.

<sup>4</sup> ARPA Valle d Aosta, Sezione Agenti Fisici ed Energia, AOSTA, ITALY

<sup>5</sup> FIORAD S.r.l., COSENZA, ITALY

<sup>6</sup> MIUR, ROMA, ITALY

Over the years, the measurement of radon gas in the soil has become a tool for indirectly assessing the radon risk in confined environments and providing elements of knowledge on the geology and nature of the soil in different territories. Therefore, the measurement of radon gas in soils can be considered a tool for the classification of areas that have different concentrations of radon activity. In Italy the Legislative Decree n.101/2020 (transposition European Directive 2013/59/Euratom), has sparked new interest in these topics not only from a radioprotection point of view, but also geophysical aspects of great interest. This work describes the experience of the Laboratories for the Measurement of Environmental Radioactivity of Research Institutes and Environmental Protection Agencies: CREA, ARPA Calabria, ARPA Piemonte, ARPA Val D'Aosta, and FIORAD carried out in the field for the measurements of radon gas in soil during the National Intercomparison by ASSORADON and AIRP (May 2022). The measurements were carried out in Caffarella Park (Appia Antica Regional Park), from the Alban Hills towards Rome. This area is of considerable interest for aspects of geology and for lithological differences (alluvial deposits, Pozzolanelle and Lionato Tuff of the eruptive unit, black and red pozzolans). The area was divided into two different sites (hilly and flat) where exercises were carried out to determine the concentration of radon gas in the soil, at various sampling points. Each Laboratory used different sampling techniques with soil probes approximately one meter long. Different measurement methodologies and algorithms were then compared. In this work, the results of the concentrations of radon activity in the soil (Rn-222, kBq/m<sup>3</sup>) are proposed, with an associated uncertainty for each measurement site and for each sampling point. The data were validated by the Organizers of the Intercomparison. The results obtained in the field survey showed the validity of radon gas measurements for the lithological characterization of different sites and as monitoring system, indicator of soil health and quality.

### NEW WAYS OF REPRESENTING SOIL: DRAWINGS ACTORS IN SOIL'S MILIEU

M. BONVEHI ROSICH, S. DENIZEN

Washington University of St Louis, St. Louis, USA

Traditional images of soil already have a difficult problem to solve, which is the familiar representational paradox of how to represent both objects and processes. All soil is said to consist of particles of three sizes—sand, silt, and clay— weathered from an original geologic parent material. However, the processes of the material can be more important to its identity than the ratio of these three constituent particles. In the case of urban soils, things happen all the time that may never happen again in human history, and its not clear which of them might recur often enough to produce the repeating patterns that taxonomic thought requires. In this sense, the end of natural history for soil is not the end of soil science, nor is it the end of taxonomic thought, it is simply the end of the long 20th century project to produce universal soil knowledge.

In order to include both material and processes in the representation of soil. We have described a new way of drawing soil both for general public but more in particular to designers that will depict a location Milieu.

To do so soil will be represented by a number of soil characters which are agents in the soil milieu. Each portrait will embrace this balance between objects and processes that we hope has pragmatic value as a faithful reflection of the material relationships elaborated. The method developed for drawing each soil portrait closely reflects a method for researching it.

In this poster, we seek to produce descriptions of soil that acknowledge the full range of human and non-human desire that participates in the process of the soil's formation and, for ethical reasons, we want to produce this portrait of the emergence of the soil's identity. These soil portraits are the set of human and non-human relationships that contribute to the soil's formation rather than the shapes that contribute to the soil's physical appearance.

### TRANSLATING SOILS THROUGH DRAWING: AN ALGORITHMIC LANGUAGE TO REPRESENT SOIL DYNAMICS

L. HARRIS, T. GALI-IZARD, Z. MA

ETH Zurich, Zurich, SWITZERLAND

Representing the complexity of soils requires a delicate process of translation, whereby specific properties of a particular soil are abstracted into a drawing. Such representations are not neutral. In design disciplines such as landscape architecture, drawings are the basis for iterative spatial thinking. Thus, what is (or is not) included in the drawing can have dramatic effects on the eventual outcome of the design process. This is very much the case when representing the heterogenous characteristics of soils. Tools for representing soils that enable their consideration as living systems in processes of urban transformation are therefore much needed.

This poster will present a drawing language that supports the development of dynamic soil diagrams. Here, data such as soil texture, organic matter content and available water content are rigorously translated through a standardized drawing language. By representing different soil profiles consistently, it is possible to quickly compare key elements to understand the potentials of each condition. Since the drawings are developed with parametric drafting software, it is possible to quickly modify them to represent change over time or possible design iterations.

The drawing language is a simple structure that is informed by widely accepted scientific understandings of soil. This structure is of course reductive; in order to retain legibility, many of the elements that make a soil unique are not included. Such abstraction is necessary for clear design thinking. Additionally, the simplicity of the language invites ongoing revision and evolution. It is introduced as part of the first semester of the ETH Zurich Master of Landscape Architecture program and students modify the drawing language to respond to particular conditions, such as the complexities of urban soils. In this way, the drawing language adapts in response to soils that it encounters, evolving through regular use and collective input to be able to represent the heterogenous anthropogenic soils that increasingly define our urban environment.

### THE GLOBAL SIGNIFICANCE OF SOIL SCIENCE EDUCATION: INNOVATIVE EDUCATIONAL APPROACHES AND LOCAL COMMUNITY IMPACTS AT THE UNIVERSITY OF TOKAJ

T. KÖPECZI-BÓCZ

University of Tokaj, Sárospatak, HUNGARY

Drawing on the experience of soil education at the University of Tokaj, we argue that soil education is of global importance, is a fundamental component of ecosystems vital to humanity, and is critical to ensuring a sustainable future (Koriem et al., 2023).

We want to engage in professional discourse with experts worldwide to develop effective methods and international cooperation. Soil science education in economics and viticulture focuses on the economic aspects of land use planning, which is topical in our region where the use of different volcanic soils in viticulture is intensive. The topics taught include "Soil quality and fertility," "Microclimate and terroir," and "Sustainable management." These topics have been chosen because they can significantly increase the market value of grapes and wine produced on the volcanic soils of Tokaj-Hegyalja and help position the region as a unique brand in terms of "Market value and branding."

In parallel with the definition of the training content, the university's methodological innovations have also focused on soil cultivation. Our applied pedagogical culture is based on constructivist pedagogy, where learners are active participants rather than passive recipients (Rygg, Kristin, et al. 2021) in creating and interpreting knowledge. Constructivism has been at the heart of pedagogical innovation for two decades (Sudzina, 1997). The methodology is particularly effective for subjects with an interdisciplinary approach, such as soil science (Koriem et al., 2023)

In designing the curriculum, we used prior sensitization, where local soil knowledge plays a prominent role in developing sustainable soil management practices (Currie, 2014). This knowledge can contribute to more effective soil conservation strategies and community soil management (Huynh et al., 2021). Involving local communities and considering their knowledge is essential for improving soil management practices. Combining local knowledge with scientific knowledge can help to develop sustainable soil management practices (Bleeker, 1983; Winkler Prins, 1999).

After evaluating the results of our pilot project, we concluded that Bronfenbrenner's Ecological Systems Theory is valid. Inland planning means taking into account the relationships between local communities (micro level), regional authorities (meso level), national policies (exo level), and global environmental trends (macro level).

We argue that using Adaptive Management in land planning is justified, which means that planning strategies are flexible and can adapt to changing environmental and social conditions.

**Purpose:** to try to understand how soil generates and works. Four experimental areas: dust on concrete square, 10 cm of raw construction sand on this same concrete, bare vegetable garden soil, cultured vegetable garden same soil.

Two radiation sensors were placed above these areas to measure the incoming (turned up) and departing (turned down) light - pyranometer (305-2800 nm) and pyrgeometer (4500-50000 nm) - from May to September. Temperature sensors were placed in the soil on the surface, at a depth of 5 and 10 cm (Figure 1). The soil was analyzed at the beginning (April) and at the end (August) of the experiment looking for: pH, totC, OC, totN, Ca, K, Mg and Na. With 3 samples per case, the following control trends were recorded: pH and CO decreased in bare soil, while they increased in the other three cases; total N increased in all cases except in vegetated soil; Ctot/Ntot increased in all cases except in bare soil; Ca increased and K decreased in all cases; Mg decreased in all except sand, while Na increased on cement and sand, and decreased in soil and vegetated soil.

Using the primers 16S for bacteria, 18S for Eukaryotes and ITS for fungi, the content in Operational Taxonomic Units of these categories of living organisms clearly distinguishes the dust of the concrete square from the other substrates, which in turn separate along a gradient that goes from sand to bare and cultivated soil. Some organisms definitely prefer dust on concrete (Cyanobacteria and Actinobacteria; Chloroplastida and Stramenipiles), others real garden soil (Chloroflexi and Acidobacteria; Eucaryota, Rhizaria and Amoebozoa; Glomeromycota).

The radiative balance is different in the 4 situations, with a shift in the balance towards redder emitted radiation when the complexity of the system increases. The study of these data is still ongoing, but we will have the definitive results to be presented to the Congress.

Figure 1. Right arm with sensor above (only) rock base soil, next to it you see the same concrete area. The left arm shows area with crops, next to area with base soil. Bottom left: area with culture after two months.

Nearly all primary biogeochemical cycles in terrestrial ecosystems predominantly happen within soils, particularly in the uppermost layers. Topsoil horizons form the humipedon that thus constitutes an interaction system and a functional transition between biotic and abiotic components.

A consortium team of specialists proposed field keys to identify and classify humus forms using descriptive and functional features as the variations in the thickness of the layers (OL, OF, OH, A), the occurrence (zoA) or not (nozA) of organo-mineral aggregates (sgA, msA, miA, meA, maA). Following the most recent classification, terrestrial humipedons spread into Terro (Mull, Moder, Mor, Amphi, Tangel), Anthropo (Agro- and Technoforms) and Parahumus (Ligno-, Rhizo-, Bryo- and Crustoforms) systems. Hence, the soil biota is at the core of the build-up of humipedon, and the A layer represents the overall engineering processe, mainly driven by plant roots and earthworms that create stable biogenic aggregates (miA, meA, maA).

Nevertheless, in regularly disturbed environments such as floodplains (Fluvisols), mountainous environments (Leptosols) and urban ecosystems (Technosol and Anthrosols), there is an intermediate step between raw materials (sediments, colluvium, recycled building debris) and stable biogenic aggregates. In such cases, the biota plays a crucial role, as do the granulometry (slab, blocks, stones, sand, etc.) and the nature (mineralogy, weathering resistance) of the parental mineral material. The French soil taxonomy has already highlighted the importance of soil texture with the J layer (from French 'jeune', young), where biogenic aggregates consist of organo-mineral aggregates, however less stable than those observed in an A layer. Consequently, the J horizon is a functional soil layer which usually evolves towards an A layer over time. Integrating this J layer in the classification of humus forms would be very useful to better describe the transition between Terro-, Anthropo- and Parahumus systems in environments containing vast amounts of raw materials. We propose to improve the current classification and add new intergrades humipedons called 'Litho' that decline in PsammoLitho, PeyroLitho and SterroLitho.

These soil types along an elevation gradient from the piedmont of the Saône River to the natural forest plateau and a terrace at a distance of 200 km (left: colluvium, right: natural forest, Litho Parahumus and Litho Anthropo) with a forest (top row) and a forest (middle row). Same 0 and 10 cm (right) and 10 cm and 20 cm (bottom row) soil aggregates and soil aggregates (left) and soil aggregates (right) that the intergrades with the formation of aggregates (middle), and finally, resistant and stable aggregates (right). The presence of aggregates and the integrity of the organo-mineral aggregates (right) are under the influence of the biota.

### SOIL METAPHORS TO SHARE KNOWLEDGE AND BUILD TRANSDISCIPLINARY REPRESENTATIONS

A. FALLOT <sup>1</sup>, A. TADDEI <sup>2</sup>, D. MASSE <sup>3</sup>

<sup>1</sup> CIRAD - SENS, MONTPELLIER, FRANCE

<sup>2</sup> Xtnt, Paris, FRANCE

<sup>3</sup> IRD - Eco&Sols, Dakar, SENEGAL

In his publications about soil pH and Redox, an agronomist compares the soil to a battery recharged by plants, which act as solar panels.

Zimbabwean farmers who met for a focus group discussion, said the soil is like a road that takes one to a desired destination.

In a Senegalese agroforestry landscape where the soil has been described as a granary, the tree is a pillar, which ensures the solidity of the construction depending on the spacing of the pillars. And the fallow period is the time needed to repair, build or rebuild.

Metaphors about soils are numerous and play a role in the way problems are addressed by scientists and by practical experts such as farmers.

Exploring metaphors as mental images to be shared and investigated can feed a deliberative process amongst stakeholders with different visions, knowledges and sciences.

Metaphors complement each other, sometimes they overlap. With metaphor-developing interviews and workshops, we brought experts to share their knowledge on soil and to grasp the limit of what can be explained by only one metaphor. Thus, we promote a plurality of metaphors and a kind of awakening of metaphorical consciousness, about their influence on representation and their heuristic power.

With more than 150 soil metaphors that we grouped into several sets (heritage, living being, communities, source of knowledge...), the collection continues and aims to involve scientists, farmers and other stakeholders in an active process where mental images can be co-constructed in dialogue.

Metaphor use for transdisciplinarity is like gymnastics that requires warming up and brings flexibility, that is, the ability to combine research from different disciplines. Gymnastics also brings strength, that is the capacity to change paradigm by integrating proposals from sometimes unrecognized experts called in for deeper metaphorical exploration.

#### AGRONOMIC APPROACHES FOR CROPPING SYSTEMS AT LOW GLOBAL WARMING POTENTIAL

D. VENTRELLA, P. GAROFALO

CREA, Bari, ITALY

In the context of Climate Change (CC), the word resilience takes on a particular and at the same time more clearly defined meaning. As suggested by the Intergovernmental Panel on Climate Change (IPCC), agriculture, and similarly the cropping systems, can be defined as resilient to CCs to the extent that they are characterized by and are based on strategies that simultaneously have a high capacity for adaptation and mitigation, i.e. that have the ability to adapt effectively to climate CCs by reducing their negative impacts on the productivity and quality of agricultural products and at the same time the ability to reduce the effects of the chemical-physical processes that cause CCs, ultimately minimizing the emissions of greenhouse gases (GHGs) that cause the CC.

The aim of this communication is to analyze agronomic practices for their ability and effectiveness of mitigation, in other words to identify the agronomic levers through which the farmer can reduce the emission of GHGs, thus optimizing cropping systems with an integrated approach that preserves crop productivity and soil fertility, minimizing their Global Warming Potential.

The analysis of agronomic practices effective in reducing the Global Warming Potential is carried out on the basis of recent meta-analyses and on the results obtained in long-term research in progress in Italy and in particular at the experimental farm Podere 124 of CREA in Foggia (Southern Italy) concerning the management of crop residues and the comparison of conservation practices with conventional tillage and minimum-tillage in the cultivation of durum wheat.

<sup>5</sup> Mineral and Energy Economy Research Institute of the Polish Academy of Sciences, MEERI, Krakow, POLAND

<sup>6</sup> ERINN Innovation Ltd, Dublin, IRELAND

Soils are healthy when they are in good chemical, biological, and physical condition, and thus able to continuously provide their important ecosystem services. DeliSoil project is embracing the opportunity offered by the circular bioeconomy to use waste and by-products from the food industry to develop organic fertilisers with the potential to replace their mineral counterpart and improve soil health in Europe. DeliSoil's overall goal is to contribute to the European Union's Mission "A Soil Deal for Europe", by enhancing soil health and improving the sustainability of food systems. This will be achieved by developing improved recycling and processing solutions for food industry residues, to produce safe, sustainable, tailored, and societally accepted soil improvers in the EU, in collaboration with the EU Soil Observatory (EUSO) and other EU projects. DeliSoil will apply a circular bioeconomy approach to the waste hierarchy through the development of 5 regional Living Labs (LLs) focused on improving soil health in Europe. DeliSoil's LLs will include the most relevant actors along the entire food value chains and will use innovative technologies to convert residues from food processing and production industries into tailored soil improvers. Research partners and companies will evaluate the soil improvers in state-of-the-art laboratories, and landowners will test the project's solutions. The tailored soil improvers will be tested for stability, biosafety, molecular parameters, and their impacts on soil health. Their agronomical performance and environmental risks will be also assessed. Environmental footprints will also be measured for selected products. We will identify technological, legislative, financial, and social barriers and enablers for the conversion of food processing residue streams into organic soil improvers and fertilising products and use these results to analyse fairness throughout the LLs value chains. Together with stakeholders, we will build communities and create networks to facilitate knowledge sharing of DeliSoil's key exploitable results. Funded by the European Union under the Horizon Europe Program, Grant Agreement No. 101112855 (DeliSoil).

### 7.09 133552 - Nature based solution for sustainable soil and water management

#### PRINCIPLES AND VALUES OF RESILIENT NETWORKS OF LONG-TERM SITES FOR RESEARCH ON AGRICULTURAL SUSTAINABILITY AND SOIL HEALTH

G. UNAMUNZAGA, C. GARBISU

NEIKER -BASQUE INSTITUTE FOR AGRICULTURAL RESEARCH AND DEVELOPMENT-, DERIO, SPAIN

At a time when agriculture is facing unprecedented, multifaceted and interlocking challenges, such as the imperative need to address food security and sustainable production in a context of climate change, loss of biodiversity and wilderness, ecological overshoot, crossed planetary boundaries, demographic growth, and socio-economic and political instability, more than ever, agricultural research is needed. Particularly, well-designed and well-conducted long-term studies are indispensable for a trustworthy understanding of agroecosystem function and sustainability. Hitherto, many long-term sites for agricultural research are focused on the evaluation of the effects of treatments (e.g., inorganic vs. organic fertilization) and, less often, agricultural systems (e.g., conventional, ecological, regenerative) on crop yield and environmental sustainability, mainly in terms of rationalization of inputs and degradation-improvement of soil health. Alas, in the light of the state of degradation of agricultural soils (soil is the basis of agroecosystem sustainability), emphasis must be placed on the long-term links between crop yield and soil health. To this aim, new principles and values must be incorporated, under the adaptive management paradigm, to the design and conduction of long-term agricultural studies. In the Basque Country (Spain), a network of long-term research sites has been established to assess the effect of different agricultural systems on crop yield, paying special attention to biodiversity conservation, climate change mitigation-adaptation and, primarily, the restoration of the functional integrity of the soil and the regeneration of the capacity and capability of the soil ecosystem to provide services. Some of the principles and values that have guided the design of the network are: (i) balance between short-term and long-term goals; (ii) technification directed towards sustainability; (iii) overcoming the dualism between production vs. conservation; (iv) overcoming the mechanistic, element-based orthodoxy when analysing soil health; (v) links between aboveground and belowground biota, biodiversity and resilience, abiotic and biotic components, and hierarchical processes-fluxes and emergent properties; (vi) an eco-ethical cosmivision that integrates the 3 Ps (people, planet, profit); and (vi) biomimicry-based strategies.

#### DESIGNING POLYSACCHARIDE CAPSULES FOR FASTER POLLUTANT TRANSFORMATION BY BIOGENIC OXIDES

Y. ZVULUNOV, A. RADIAN

Faculty of Civil and Environmental Engineering, Technion, Haifa, ISRAEL

Microbially produced manganese oxides (BioMnOx) are potent oxidants and adsorbents for a wide variety of environmental pollutants. BioMnOx are often more reactive than their abiotic counterparts, are formed under mild conditions, and are continuously replenished by the microbes; they are therefore a cheaper and more sustainable alternative to synthetic oxides. Encapsulation, which aids in recovery and reuse and minimizes washout of the cells and oxides, is especially favorable for such a self-regenerating system. In this study, BioMnOx encapsulation liquid-core capsules made of natural polysaccharides was investigated for the first time, in order to improve post-encapsulation pollutant oxidation kinetics. Two contaminants, glyphosate and bisphenol A, were selected as model compounds representing distinct oxidation patterns. Different capsule compositions were examined to ensure rapid diffusion with high preservation of the oxides and oxide-forming bacteria. Thanks to the strong relationship between oxidation kinetics and oxide levels, BioMnOx localized inside the capsules removed glyphosate significantly faster than suspended oxides, and their reuse for several treatment cycles was demonstrated. Bisphenol A, which is more sensitive to diffusion rates than to oxide concentrations, was removed by encapsulated BioMnOx at nearly the same speed as in suspension. Our results show that liquid-core encapsulation can allow efficient reuse of nature-based catalysts at reduced treatment times and catalyst inputs compared to suspended or gel-encapsulated configurations, ultimately making such catalysts more attractive and promoting sustainable remediation techniques.

#### IMPACT ON SOIL QUALITY AND LEACHATE UNDER AVOCADO CROPS IRRIGATED WITH WASTEWATER

P. HUESO GONZÁLEZ<sup>1</sup>, M.M. KHARYTONOV<sup>2</sup>, C. MORENO ALARCON<sup>1</sup>, J.D. RUIZ SINOGA<sup>1</sup>

Mediterranean areas are characterized by a strong spatial variability that makes the soil hydrological response highly complex. Some seasons provoke dramatic changes on soil properties determining the runoff rates, such as soil water content or soil water repellency. Regarding the adaption of water needs to local conditions, important advances have taken place in the last years thanks to the use of different parameters to evaluate the water status of soil. The hydrological response of a soil is defined by: (a) the surface characteristics; (b) the physical, chemical, and biological properties that define it, and (c) the hydrologic properties. Estimation of the water status of the soil has been widely used in soil science as a tool for quantitative analysis. Main objective of this case study was to analyze technosol and irrigation water physical and chemical properties dynamics in the pot experiment with lysimeters. Pot experiment with Avocado rootstocks was equipped with lysimeters in the facilities of the "La Mayora Experimental Field site" of the Higher Council for Scientific Research (Spain). The scheme of the pot experiment included three sources of irrigation: a) ground water; b) regenerated municipal wastewater (100%); c) mix of ground and regenerated municipal wastewater (50 / 50%). Chemical analysis data indicate that the reclaimed wastewater does not meet irrigation requirements in terms of pH, EC and due to the significant content of sodium and chlorine. Even groundwater satisfies irrigation water qualitative requirements partially. The suitability of irrigation water on pH level can be characterizes mainly as unsuitable and doubtful. Diluting regenerated wastewater with groundwater following the 50% principle led to decreasing of the potential risks for salinization of ground water connected with leaching of the leachate. The dynamics of the change in the volume of leachate is related to precipitation, the frequency of irrigation and different manifestations of the physical, mineralogical and chemical properties of technosols.

#### NATURAL MINERAL-BASED SOIL CONDITIONERS

S. NÉMETHY<sup>1,2,3</sup>, L. CSIGE<sup>3</sup>, M. TÓTH<sup>4</sup>, P. MOLNÁR<sup>1</sup>, G. NAGY<sup>1</sup>

<sup>1</sup> University of Tokaj, HUNGARY

<sup>2</sup> University of Gothenburg, SWEDEN

<sup>3</sup> University of Debrecen, HUNGARY

<sup>4</sup> Gróf Degenfeld Wine Estate, Tarcfal, HUNGARY

In the past fifty years, the nutrient supply of soils has been severely weakened in agricultural areas, mainly due to large-scale monoculture and intensive cultivation methods based on short-term synthetic fertilizers. Soil minerals have many functions, such as increasing the nutrient absorption capacity of plants, adjusting the pH of soils, and providing nutrients to plants. Mineral based soil conditioners can be divided into two main groups according to their use and recoverability: In the soil zone (in the depth of the soil profile) and below the soil zone (deeper situated materials). The first group, materials originating from the soil zone, include:

1. materials of marshland soils (peat, marshes, moss, lime mud),
2. top layers of meadow soils (containing clay minerals and humus) and loess,
3. calcareous formations in the subsoil of higher lying fields of the saline lowland areas.

The second group, the deeper materials below the soil zone represent the most diverse category of natural mineral soil conditioners:

1. limestone (monomineral, mostly biogenic, sometimes chemical sedimentary rock, calcium carbonate content at least 90%, mostly calcite),
2. dolomite (calcium-magnesium carbonate trigonal crystalline mineral),
3. alginite (sedimentary rock composed of algae biomass and volcanic tuff), mined in the region of Gércse, Hungary,
4. zeolites (sodium calcium aluminosilicates, spacious, hollow, porous),
5. rhyolitic tuff (volcanic, high silica, sour, contain pumiceous, glassy fragments and small scoriae with quartz, alkali feldspar and biotite),
6. perlite (high-water holding capacity, felsic, by heating heavily swollen glass rock), marl (sedimentary, clay-carbonate rock),
7. bentonite (a clay-type, dominant elements may be aluminium, potassium, calcium and sodium, with a water retaining capacity of 15 - 20 times its volume),
8. potassium trachyte (high potassium spillage rock with white, sanidine crystals),
9. sanidine is the high temperature form of potassium feldspar with a general formula  $K(AlSi_3O_8)$ , mixture of gypsum anhydrite and lignite powder,
10. dudarite NPK (brown coal-based soil enhancer with more than 60% humic acid content mined in the Dudar area, Hungary).

Improving the soil's natural mineral content is an important part of healthy plant cultivation and essential for modern organic farming. Natural mineral soil conditioners do not conflict with each other and do not cause problems when used together. However, it is unnecessary to exceed the recommended application rates.

**Keywords:** mineral-based soil conditioners, marshland soils, dolomite, limestone, alginate, zeolites, rhyolitic tuff, perlite, bentonite, potassium trachyte, sanidine, dudarite, soil pH, nutrient absorption capacity

#### PLANTS RESPONSE TO HOUSEHOLDS ASHES IN SOILS – AN EXPERIMENTAL APPROACH WITH RAPHANUS SATIVUS AND SPINACIA OLERACEA

A. PEDZIWIATR<sup>1</sup>, A. POTYSZ<sup>2</sup>, L. UZAROWICZ<sup>1</sup>

<sup>1</sup> Warsaw University of Life Sciences, Warszawa, POLAND

<sup>2</sup> University of Wroclaw, Wroclaw, POLAND

Coal combustion in households generate ashes. Field observations demonstrate that people use household ashes as additives in garden soils. Thus, the aim of our study was to determine the plants response to household ashes in cultivated soils. Furthermore, the research focusing on the effect of *Pseudomonas fluorescens*, soil bacteria, on metal(loid)s mobilization in ash amended soils, is ongoing.

Soils were collected from arable field and from garden in central Poland. Following treatments were prepared: (a) control soils, (b) soils with 10% of ash from household 1, (c) soils with 10% of ash from household 2. Two plant species were cultivated consecutively: *R. sativus* and *S. oleracea*. Afterwards, chemical composition of soils and plants as well as soil properties were determined.

Ash from household 1 was characterized by the higher content of Ni, Cu, and Cr (up to 185 ppm of Cr) relative to ash originating from household 2. In turn, higher contents of Zn, Pb, Co, and As were noted in ash from household 2 (up to 1897 ppm of Zn) relative to household 1. The addition of household ashes to soils increased metal(loid)s content in soils. Both ashes also increased the pH, C and S content of both soils. The effect of ashes on chemical composition of plants was also observed. For example, Al content in roots and leaves of *R. sativus* increased in all treatments compared to control soils. In turn, zinc content in this plant species mostly increased in garden soil amended with household ash 2 (up to 74 ppm). The uptake of Al and Zn by *S. oleracea* was more diversified.

Our study demonstrated that addition of household ashes to soils can improve some soil properties like pH. However, household ashes are the source of metal(loid)s leading to increase of elements in plants and yield of such elements. Therefore, soil fertilization with household ashes is not recommended due to the potential toxicity effects.

#### COMBINATION OF IN-SITU ENHANCED SOLUBILIZATION AND CHEMICAL OXIDATION TECHNOLOGIES FOR THE REMOVAL OF DNAPLS FROM SOILS

T. ONAY, Z. DEMIRAY

Bogazici University, Istanbul, TURKEY

Contamination by low-solubility organic contaminants in the form of dense non-aqueous phase liquids (DNAPLs) is a widespread problem influencing numerous groundwater system. Over the past decades various technologies have been testing for the removal or in-situ remediation of DNAPLcontaminated subsurface systems, such as in-situ enhanced solubilization (ISES) and in-situ chemical oxidation (ISCO). This study examines the synergetic effects of combined surfactant enhanced dissolution with in-situ oxidation of a pool-dominated DNAPL sources zone entrapped in heterogeneous porous media. The experiments are used to investigate the impact of DNAPL source zone architecture, surfactant-enhanced dissolution, and permanganate oxidation on removal behavior and to assess the interaction of the surfactant-enhanced and chemical oxidation processes. Results show that enhanced removal of entrapped DNAPL mass from soil can be achieved when these two remediation processes are jointly applied. Critical factors include the contact time between the water and the solubilizing solution as well as the potential interference of the solubilizing agent with the oxidation process.

### SAPROLITE AND REGOLITH AS CRUCIAL STRATA OF THE SUBSOILS IN THE MID-LATITUDES – EXAMPLES FROM THE BAVARIAN FOREST (GERMANY)

J. VÖLKEL, A.H. HOLMER, Y. ZHUANG, S. PUTZHAMMER

Technical University of Munich, Munich, GERMANY

Saprolite is the product of long term chemical weathering derived from underlying rock e.g. within crystalline landscapes like the Moldanubian Massif (Bavarian Forest). In these terms it is the zone of weathered rock. Regolith is known as the interplay of processes that break down rock with processes that weather and transport. Regolith as well as saprolite are controlling the properties of the critical zone as the weathered profile. In many soilscapes they function as subsoil substrates. Rock strength, regolith and saprolite thickness, hydraulic transmissivity, chemical weathering fluxes, tree rooting depth and nutrient availability all depend to some degree on the thickness and character of the weathered profile. The Bavarian Forest is presenting quite a lot of examples. In bedrock land- and soilscapes, those dominated by bare rock and soils derived from underlying rock, the interplay of processes that break down rock with processes that weather and transport regolith as well as saprolite controls the properties of both the subsoils and the critical zone. Regolith is often generated by periglacial slope processes and their deposits (PSD). PSDs cover nearly all mid- and high mountainous landscapes, even in the Mediterranean region. The genesis of Saprolite refers to Mesozoic times, often starting in the late Paleozoic, depending on the tectonic expression of landscapes. In our investigation area Saprolite genesis started in Jurassic times without any interruption until the Quaternary. Saprolite is characterized by mineralogical and geochemical parameters. The spatial variations in weathered profile characteristics are discussed. Beside sampling soil pits and cores from percussion drilling the prospection of the shallow subsurface is based on geophysical exploration, mainly Electrical Resistivity Tomography (ERT) and Ground Penetrating Radar (GPR), but also on Shallow Seismic Refraction (SSR).

### THE IMPORTANCE OF SUBSOIL WHEN INVESTIGATING SOIL ORGANIC CARBON PERSISTENCE IN PERENNIAL AGROECOSYSTEMS WITHIN ALPINE VALLEYS.

E.R. FOLEY<sup>1</sup>, R. TIZIANI<sup>1</sup>, L. BORRUSO<sup>1</sup>, E. TASKIN<sup>1</sup>, S. CESCO<sup>1</sup>, T. MIMMO<sup>1,2</sup>

<sup>1</sup> Faculty of Agricultural, Environmental and Food Sciences, Free University of Bolzano, Bolzano, ITALY

<sup>2</sup> Competence Centre of Plant Health, Free University of Bolzano, Bolzano, ITALY

Studies on soil carbon (C) dynamics to date focus primarily on topsoil, despite an estimated ~50% of soil C being stored in subsurface soils. These deeper soil layers are thought to be dominated by C that has formed mineral-associations and is more persistent than its labile counterpart. Understanding the efficacy of this could be critical in developing practices aimed to mitigate climate change by increasing C storage in agricultural soils. The aim of this study is therefore to explore differences in soil C fractions in topsoil and subsoil in perennial agroecosystems, to gain an understanding of how C dynamics change along the soil horizon. For this purpose, soil samples at 0-30 cm and 30-60 cm were collected from four apple orchards in South Tyrol, Italy. Samples were analysed for labile C fractions (dissolved organic carbon (DOC), humic and fulvic acids (HA/FA), hot water extractable carbon (HWEC), permanganate oxidisable carbon (POXC), particulate organic matter (POM)) and the stable C fraction (mineral-associated organic matter (MAOM)).

Results indicate that soil samples taken from deeper layers contained significantly lower concentrations of labile C fractions (HWEC, POXC and POM) across all sites, with HWEC measuring up to 2 times lower in subsoil. However, when examining the MAOM, results show the proportion of stable (MAOM) to labile (POM) C was significantly higher in the subsoil, with MAOM constituting ~73% in subsoil, and just ~61% in topsoil. Furthermore, the concentration of C in the MAOM was ~2 times higher than in the POM. These results highlight the importance of subsoil in the study of soil C storage, as indicated by the larger proportion of MAOM. Furthermore, it underlines the importance of identifying and quantifying C fractions at different sampling depths and understanding their associated turnover rates. This will facilitate a deeper comprehension of C cycle dynamics within these environments and will in turn provide insight into the relevance of subsoil when studying C dynamics in agroecosystems.

### STABILIZATION OF ORGANIC CARBON IN TOP- AND SUBSOIL BY BIOCHAR APPLICATION INTO CALCAREOUS FARMLAND

Y. WANG, J.Y. SHANG

China Agricultural University, BEIJING, CHINA

Biochar is recognized for its role in carbon sequestration and emission mitigation in farmland topsoil. However, the mechanisms by which biochar affects soil organic carbon (SOC), its composition, and stability, in the topsoil (0–20 cm) and subsoil (140–160 cm) remain unclear. Applying biochar to the calcareous farmland topsoil significantly increased the topsoil SOC contents by 33 % after a decade, with a 5 % increase in dissolved organic carbon (DOC) contents (topsoil) and a substantial increase of 162 % in subsoil DOC contents. Additionally, humic substances showed an increase of 24 % (topsoil), while low-molecular-weight water-extracted DOC exhibited a remarkable increase of 142 % in the subsoil. The application of biochar significantly increases the contents of SOC, DOC, and microbial biomass carbon (MBC) in the topsoil, as well as SOC and DOC contents in the subsoil. However, a slight decrease is observed for MBC content in the subsoil. Biochar-amended soil significantly suppressed enzyme activity in the topsoil and decreased alpha diversity in topsoil and subsoil while increasing the content of mineral-associated soil organic matter (MAOM). These observed changes are conducive to stabilizing SOC, emphasizing MAOM formation as a primary mechanism for carbon sequestration in both topsoil and subsoils. This study provides evidence that biochar contributes to the long-term organic carbon sequestration in calcareous farmland, highlighting the importance of considering both topsoil and subsoil when evaluating the dynamic impacts of biochar on SOC.

### BIOCHAR STIMULATES INORGANIC CARBON PRECIPITATION IN THE SUBSOIL

J. SHANG, Y. WANG

China Agricultural University, Beijing, CHINA

Biochar amendments add persistent organic carbon to the soil and can stabilize rhizodeposits and existing soil organic carbon (SOC), but the effects of biochar on subsoil carbon stocks have been overlooked. We quantified changes in soil inorganic carbon (SIC) and SOC to 2 m depth ten years after biochar application to calcareous soil. Biochar application at 30, 60, and 90 t ha<sup>-1</sup> rates significantly increased SIC by 10, 38, and 68 t ha<sup>-1</sup>, respectively, with accumulation mainly occurring below 1 m. To explain SIC accumulation in subsoil with biochar amendment, the interacting mechanisms are proposed: (1) biochar amendment significantly increases subsoil pH, and (2) the transported biochar in subsoil can act as nuclei to precipitate SIC. Biochar amendment enhanced SIC by up to 80%. Thus, the effects on carbon stocks in subsoil must be understood to inform strategies for carbon dioxide removal through biochar application. Biochar incorporated into calcareous topsoil significantly stimulates soil inorganic carbon storage in the subsoil, which provides new insight into biochar's effect on soil carbon stocks and is beneficial for CO<sub>2</sub> removal strategies. Our study provided critical knowledge on the impact of biochar application to topsoil on carbon stocks in subsoil in the long term.

### SUBSOIL CONSTRAINTS FOR CROP PRODUCTION: RECENT ADVANCES, NEW TECHNOLOGIES AND PRIORITIES FOR FURTHER RESEARCH

R. BELL <sup>1</sup>, T. DE OLIVEIRA <sup>2</sup>

#### Affiliations

<sup>1</sup> SoilsWest, Centre for Sustainable Farming Systems, Murdoch University, Murdoch, AUSTRALIA

<sup>2</sup> Department of Soils, Federal University of Vicosa, Vicosa, BRAZIL

Globally, the existence, prevalence, and severity of subsoil constraints for crop production are under recognised and under reported. A diverse range of subsoil constraints (acidity, alkalinity, compaction, deep sand layers, gravel layers, high density horizons, nutrient deficiencies, pans, pathogens, salinity, sodicity, waterlogged horizons) may be natural features of soil profiles and some are induced by land use and management practices. The subsoil in this context is considered to be the layers of the root zone below the depth of sampling for soil analysis, which typically corresponds to soil below 10-25 cm depth, depending on the soil sampling conventions of the region. Tropical regions, in particular (in Africa, Asia, Northern Australia, and Latin America), contain large areas of deeply weathered profiles that commonly have hostile subsoils that constrain root growth. The main consequence of subsoil constraints is that water and nutrient contained in subsoils are not accessed or efficiently utilized and hence crops fail to reach their yield potential. Even when best management practices are applied to the topsoil, yield of crops is depressed by subsoil constraints. Crops may acquire up to 75% of N, 85% of P and 70% of K uptake from the subsoil if root growth is not constrained. Technologies to chemically, physically and or biologically ameliorate subsoil constraints represent a promising frontier for soil management, with the potential to substantially lift crop productivity in many parts of the world. In addition, technologies are needed to accurately sense, identify and map digitally the existence and distribution of subsoil constraints.

### A NEW NONPARAMETRIC WATER ISOTOPE MIXING MODEL FOR PLANT WATER SOURCING

B.C. SI, H. FU

University of Saskatchewan, Saskatoon, CANADA

The knowledge of where and when plants absorb water in soil is critical to understanding how plants cope with drought and to precision management. However, current mixing models such as MixSIAR are inaccurate and exhibit high uncertainty. To address this limitation, this study introduced a nonparametric B-spline to approximate the root water uptake pattern, thereby creating CrisPy-Spline mixing model. To evaluate the performance of CrisPy-Spline, we conducted virtual and field-based tests under various prior information and results were compared to CrisPy and MixSIAR. In the virtual tests, CrisPy-Spline demonstrated RMSE of root water uptake proportions ranges of 10.7%-38.7%, and smaller than that from MixSIAR (17.8%-43.1%). Additionally, CrisPy-Spline consistently showed the lowest uncertainties of root water uptake profiles among the three models. Further assessments through posterior predictive checking revealed accurate reconstructions of plant water isotopic distributions by CrisPy-Spline under all prior information. They displayed mean absolute error in the mean of plant water isotope composition of  $^{18}\text{O}$  at 0.056‰ and 0.076‰, respectively, with mean absolute errors in the standard deviations at 0.008‰ and 0.008‰, respectively. By contrast, MixSIAR exhibited higher mean absolute errors in the mean and standard deviation of plant water isotope composition of  $^{18}\text{O}$  at 0.285‰ and 0.244‰, respectively. In the field test, available soil water and fine root distribution were used as the prior information. CrisPy-Spline exhibited the least uncertainty of root water uptake among the models. Moreover, when anticipating almost zero root water uptake from a certain depth interval based on soil water availability information, only CrisPy-Spline and MixSIAR aligned with this feature. Furthermore, leave-one-out cross-validation demonstrated that CrisPy-Spline exhibited the highest expected log pointwise predictive density (-3.3) compared to MixSIAR (-4.5), indicating a superior accuracy of CrisPy-Spline. Therefore, CrisPy-Spline can be a robust tool for plant water partitioning.

### SHALLOW SOILS DERIVED FROM AND UNDERLAIN BY SILICATE SOLID ROCKS IN COLD ENVIRONMENTS: PROPERTIES, MINERALOGY, AND GENESIS

S. LESSOVAIA

St.-Petersburg State University Department of Physical geography, ST. PETERSBURG, RUSSIA

The shallow soils derived from and underlain by solid silicate rocks in the cold environments of the tundra and taiga zones of Eurasia are mostly acidic and enriched in organic matter and Fe and Al compounds. Study of these soils allows to assess: (i) patterns of initial soil formation; (ii) allochthonous or autochthonous origin of the soil fine earth, and (iii) weathering and alteration of inherited minerals in the soil profiles. Summarizing the results, several soil groups depending on the presence of phyllosilicates in the solid rocks can be considered.

(i) Inceptisols and Spodosols on the rocks with low contents/ absence of phyllosilicates. The soils have formed in the autochthonous fine earth accumulations, mostly formed due to rock disintegration. The initial stage of fine earth formation affected by biofilms was also disclosed: in the autochthonous accumulations the rock fragments remain attached to the solid rock due to the release of extracellular polymeric substances by the biofilms.

(ii) Inceptisols and Spodosols with different assemblages of inherited clay minerals. Soil mineralogy reflects the influence of the subjacent solid geology leading to the occurrence of the inherited minerals that are rare in acidic soil environment (talc, serpentine, nontronite, and saponite) in the soil profiles. Pedogenesis can enhance the weathering of the contribution of inherited minerals (micas, chlorite) into mixed-layer structures including swelling clay and vermiculite. Besides, rock weathering led to the formation of iron-clay-organic coatings on the surface of rock fragments retarding its further weathering and protecting inherited minerals.

(iii) The rare example of Gelisols that are alkaline oppositely to the groups mentioned above and that have developed from the ultramafic rock. Whereas intensive chemical weathering of inherited silicates (olivine, serpentine) led to smectite occurrence in the profile that is absent in the rock. That illustrates the scenario of soil formation slightly affected by pedogenesis, but from the "mature" fine earth due to the chemical weathering.

### THE DYNAMICS AND HIGH-RESOLUTION DISTRIBUTION OF AL FORMS IN A DESERT PALAEO SOL (CENTRAL IRAN): ENVIRONMENTAL IMPLICATIONS

O. BAYAT<sup>1</sup>, A. KARIMI<sup>2</sup>, M. PLOTZE<sup>3</sup>, M. EGLI<sup>1</sup>

<sup>1</sup> Department of Geography, University of Zurich, Zurich, SWITZERLAND

<sup>2</sup> Department of Soil Science, Ferdowsi University of Mashhad, Mahhad, IRAN, ISLAMIC REP

<sup>3</sup> Institute for Geotechnical Engineering, ETH Zurich, Zurich, SWITZERLAND

<sup>4</sup> Department of Geography, University of Zurich, Zurich, SWITZERLAND

Aluminum is one of the most important and abundant elements on Earth's surface. The dynamics of this element has been widely studied in acidic soils and in the soils of the Mediterranean bioclimatic regions while there are very limited data about the dynamics and forms of Al in Aridisols. The aim of this study was to evaluate the dynamics of Al forms in a relict palaeosol and its environmental significance in an arid setting of central Iran. The studied soil is located on an upper terrace without impacts of groundwater and alluvial materials from adjacent landforms. We investigated different forms of aluminum (total (Alt), amorphous (Alo) and crystalline (Ald)) and also the mineralogical composition of the soil using a high-resolution sampling strategy (10 cm interval). The soil has the highest content of total Al near the surface. The amount of crystalline aluminum is the highest in the middle part of the pedon and does not show any significant trend with depth while the amount of amorphous aluminum, the Allophane index ( $Alo + 0.5Feo$ ) and Alo/Ald ratio increased exponentially towards the soil surface. Mineralogical analyses revealed that the clast fraction of the soil lacks in smectite and K-feldspar minerals while smectite is abundant in fine earth fraction in the middle part of the pedon. The K-feldspar content increased exponentially towards the soil surface with a maximum content in dust-derived vesicular horizons. These findings suggest the formation of smectite in the soil environment by pedogenic processes and the addition of K-feldspar onto the soil surface by dust. Therefore, the soil experienced a profound environmental change from an environment that was characterized by chemical weathering to an environment of the accumulation of Al-bearing dust. Our study highlights the importance of the dynamics of aluminum in arid soils which must be considered for paleoenvironmental reconstructions as well as considering Al as a product of hydrolysis processes and an immobile element of weathering in soils.

<sup>5</sup> Task Force on Microbiome Studies, University of Naples Federico II, Naples, Italy., Naples, ITALY

Charcoal kilns are ancient structures used for charcoal production. The aim of this study was to describe the chemical and microbiological features of soil and charcoal particles collected in kilns platforms. Kilns from two mountain sites i.e., Gelbison and Vesole located in Southern Italy, were selected. Standard soil chemical analyses i.e., pH, organic carbon, salinity, macro- and micronutrients, were combined with next-generation sequencing techniques to describe bacterial and fungal microbiome. Charcoal species identity was studied by anthracology approach while imaging through scanning electron microscopy (SEM) combined with energy dispersive X-ray spectroscopy (EDS) was performed to characterize the topological and elemental composition of charcoal particles. Moreover, reflectance Fourier transform infrared spectroscopy (DRIFTS) was used to assess biochar surface oxidation. Finally, we also conducted a bioassay with three crops, Glycine max, Zea mays, and Solanum lycopersicum, to investigate the potential effects of the soil kiln on plant performance. Contrary to our hypothesis, the soils of charcoal kilns don't have higher pH, cation exchange capacity, and is not richer in cations i.e. N, P, K, Ca, and Mg. SEM-EDS spectra and FTIR revealed that charcoal buried in forest soil for decades undergoes substantial oxidation compared to recently produced charcoal. In fact, the O/C ratio rises considerably while the FTIR has shown the presence of oxygenated functional groups including phenolic, alcoholic, and carboxylic. Charcoal surface was selectively enriched of Ca<sup>2+</sup> on the site with limestone parent rock but of Al and Si over sedimentary (flysch) substrate. The differences between the soil of the kiln and the surrounding were significant but not dramatic, both in terms of diversity and composition of taxa. Finally, the bioassay with three crops suggests the microbiome present in the kiln has a greater beneficial effect than that of external forest soil. This study revealed the unicity of kiln microsite and began to discover the long-lasting effects of charcoal accumulation in modulating soil chemistry and microbiota in forest soil.

### UPPER PLEISTOCENE PRECIPITATION VARIABILITY FROM COZUMEL ISLAND (MEXICO), FROM RECORDS OF THE EPIKARSTIC (SOILS) AND KARSTIC (SPELEOTHEM) SYSTEMS

D. VALERA FERNÁNDEZ , R. LÓPEZ MARTÍNEZ

Instituto de Geología, Universidad Nacional Autónoma de México, Ciudad de México, MEXICO

In tropical and subtropical regions, stalagmites may represent archives of past hydroclimatic information; their carbon and oxygen isotope composition may be related to the amount of precipitation. The macro- and micromorphological characteristics of the soils may also indicate different moisture-drought Yucatan Peninsula (YP), most of these records in the karstic and epikarstic systems address the temporality corresponding to the Holocene and focus fundamentally on the evidence of the droughts that could have caused the Mayan civilization's collapse. In this study, a speleothem from the Island of Cozumel is analyzed for the first time, and we present oxygen and carbon isotopic records from that span the time interval between 22.3 and 11.8 ka BP, from the 2-meter-long stalagmite named "Chempita." The  $\delta^{18}O$  values for the period between 22 and 13.8 ka BP are the slightest negative in our record,  $\sim -1.5$  ‰ on average; these values suggest a low level of precipitation. Our data indicated an increase in precipitation over a time interval of  $\sim 440$  yr between 13.8 and 13.4 ka BP with the most negative values of  $\delta^{18}O$  ( $-3.05$  ‰). For this temporality YP, there is evidence of the formation of soils with Btk horizons that present illuvial cutans related to humid conditions. For the subsequent period between 13.4 and 11.8 ka BP, the value of  $\delta^{18}O$  increases; they suggest an aridization process related to the appearance of carbonate nodules in the Btk horizons of the soils. On the other hand,  $\delta^{13}C$  values do not vary considerably throughout the entire record, with values that could suggest the presence of little vegetation cover, especially C4-type plants. Only in the time interval 13.8 -13.4 ka BP are the values lower, possibly because of greater humidity. These results provide a better understanding of regional precipitation variability.

<sup>3</sup> University of Lleida, Lleida, SPAIN

<sup>4</sup> University of Zagreb Faculty of Mining, Geology and Petroleum Engineering, Zagreb, CROATIA

<sup>5</sup> Belgian Nuclear Research Centre SCK CEN, Mol, BELGIUM

<sup>6</sup> Geological Survey of Serbia, Beograd, SERBIA

The study was carried out on the pedosedimentary complex in coastal region of Croatia. The aim was to describe the pedological and mineralogical properties of the palaeosols and to compare them with the recent soils.

The field investigations comprised the definition, description and sampling of palaeosol horizons of the 8 m thick sequence of glacial-fluvial deposits, palaeosols and recent soils. The pedological analyses were carried out using standard methods. The mineralogical composition was determined using the X-ray powder diffraction method.

The pedological properties: soil texture, bulk density, porosity, pH, SOC, CaCO<sub>3</sub> of paleosols show great variations. Comparison of the properties of palaeosols with those of recent soils shows considerable differences. The palaeosols are predominantly reddish in colour and have a significant amount of carbonate concretions and rhyzoconcretions, whereas the recent soils are brownish and without carbonate redistributions. The palaeosols are characterised by a higher percentage of sand particles and a lower percentage of silt particles than the recent soils. The recent soils have higher pH values and SOC contents, and lower CaCO<sub>3</sub> contents than the palaeosols.

The mineralogical composition of palaeosols and recent soils consists of quartz and calcite with feldspars (K-feldspar and plagioclase), goethite and clay minerals (kaolinite and mica). They differ in the presence of chlorite, which was recorded only in the recent soil, while Ti- and Mn-oxides, Ch-hydroxides were only found in the palaeosols.

The results show that the palaeosols were subjected to intense pedogenesis, consisting of sequences of carbonate leaching, rubefaction and clay illuviation; which is typical of a warm and humid climate and in which stable minerals (kaolinite, Fe- and Mn- oxides and hydroxides) predominate in the sediments under oxidative conditions. In contrast to the palaeosols, the recent soil has a mineral composition that is more typical of a climate with cold, dry winters and warm, humid summers.

## PALEO-GEOMORPHOLOGICAL AND MINERALOGICAL EVIDENCE FOR THE DEFINITION OF TIMING AND CLIMATE FRAMEWORK OF PALEOSOLS IN THE PALEOVULSINI VOLCANO (VULSINI VOLCANIC DISTRICT, CENTRAL ITALY)

G.M. DI BUDUO <sup>1</sup>, M. GAETA <sup>2</sup>, D.M. PALLADINO <sup>2</sup>, F. MARRA <sup>3</sup>, L. ALDEGA <sup>2</sup>, S. VINGIANI <sup>4</sup>, S. MARINARI <sup>1</sup>

<sup>1</sup> Università degli Studi della Tuscia - Dipartimento per l'Innovazione nei Sistemi Biologici, Agroalimentari e Forestali, Viterbo, ITALY

<sup>3</sup> Istituto Nazionale di Geofisica e Vulcanologia, Roma, ITALY

<sup>4</sup> Università degli Studi di Napoli Federico II - Dipartimento di Agraria, Portici (NA), ITALY

Two successive paleosols within the middle Pleistocene volcanic sequence of the Paleovulsini volcano (Vulsini Volcanic District, central Italy) have been analyzed in terms of paleo-geomorphological and mineralogical features. The paleosols, located in the eastern sector of the Vulsini District nearby Sermugnano and in hard-to-access outcrops around Civita di Bagnoregio, showed apparently similar for thickness and color variations, but different for paleo-morphological settings (planar / channel fill / slope inclined at 25°-30°). The lower paleosol (SER1) developed from a pumice fall level dated 589±1 ka and its pedogenesis was probably interrupted by a colluvial deposition, giving rise to a new cycle of pedogenesis. The C horizon of SER1 showed a trachytic composition with a primary mineralogy mainly made up of K-feldspars (sanidine), Na-feldspar (albite), Ca-clinopyroxene (augite) and phlogopite mica, associated with sparse secondary montmorillonite and pyrite, proving an alteration occurred under reducing conditions. The upper paleosol (SER2) was sealed by a non-erosive welded pyroclastic flow deposit ('nenfro') newly dated 505±1 ka. In the C horizon of SER2 are found analcimized leucite and frequent volcanic clasts of tephritic composition containing plagioclase and leucite, which indicate the deposition of a geochemically different parent material compared with the C horizon of SER1. As effect of the burial process by hot pyroclastic flow ('nenfro'), in the upper part of SER2 evidences of soil compaction, with partial lithification, and generally low content of total organic carbon were found. Based on the new date constraints, the performed analysis allowed to recognize that the development of the two paleosols occurred in an approximately 84-thousand-year time interval. However, considering that the pedogenetic processes involving SER1 and SER2 are still under study, it is difficult to exactly collocate the two paleosols within the climatic interval occurred between the beginning of MIS 15.1 and the early MIS 13.1.

### BEDROCK IN THE PALEOSOLS SEQUENCE AT LATERA VOLCANO (VULSINI VOLCANIC DISTRICT, CENTRAL ITALY) TO DEFINE TIMING AND CLIMATIC FEATURES IN THE MIDDLE PLEISTOCENE (226-253 KA)

G.M. DI BUDUO <sup>1</sup>, M. GAETA <sup>2</sup>, D.M. PALLADINO <sup>2</sup>, F. MARRA <sup>3</sup>, L. ALDEGA <sup>2</sup>, S. VINGIANI <sup>4</sup>, S. MARINARI <sup>1</sup>

<sup>1</sup> Università degli Studi della Tuscia - Dipartimento per l'Innovazione nei Sistemi Biologici, Agroalimentari e Forestali, Viterbo, ITALY

<sup>2</sup> Sapienza Università di Roma - Dipartimento di Scienze della Terra, Roma, ITALY

<sup>3</sup> Istituto Nazionale di Geofisica e Vulcanologia, Roma, ITALY

<sup>4</sup> Università degli Studi di Napoli Federico II - Dipartimento di Agraria, Portici (NA), ITALY

Three paleosols within the middle Pleistocene volcanic succession of the Vulsini Volcanic District (Central Italy) were investigated. Two paleosols are located near Canino in the southwestern sector, and one near Pitigliano in the northwestern sector (Latera volcano). The three paleosols are interbedded with pyroclastic deposits of the Latera volcanic activity and are well constrained in age to the 253-226 ka interval, allowing their correlation with the MIS 8 - 7.4 interval. The lower paleosol (CAN1) developed by trachytic pumice flow deposits during the 253-241 ka time interval corresponding to the late MIS 8 through MIS 7.5. The C horizon of CAN1 shows a primary mineralogy made up of prevalent sanidine, associated with plagioclase, Ca-clinopyroxene, phlogopitic mica, zeolites, and quartz, while hematite has secondary origin. The above paleosol (CAN2) developed by ash flow deposits between 241 and 235 ka, during the late MIS 7.5. Lack of quartz is observed in the C horizons of CAN2 at 65-70 cm of depth while scarce occurrence of quartz and presence of montmorillonite is found at 70-90 cm of depth. Scarcity of quartz is consistent with the trachytic composition (Si-saturated bedrock) of the C horizons. Then, the uppermost paleosol (PIT3) formed between 235 and 226 ka (an interval corresponding to the MIS 7.4 cold spell) by phonolitic pyroclastic flow bedrock made up of ash matrix, pumice lapilli and blocks with a mineral assemblage of sanidine, leucite turned in analcime, Ca-clinopyroxene, plagioclase, apatite and magnetite. In the C horizons of PIT3, the above mentioned primary minerals and pumice clasts are associated with secondary halloysite, smectite and quartz, which is likely allochthonous due to the Si-undersaturated bedrock composition. The present study provides the preliminary knowledge for the characterization of the paleoenvironmental conditions in which the pedogenetic processes produced the paleosols CAN1, CAN2 and PIT3.

The pedogenic processes occurred during the Middle Pleistocene were studied in a sequence of paleosols by integrating micromorphological observations of thin sections and SEM-EDS, with soil geochemical composition and selective extractions. The two oldest paleosols are located close to Canino (CAN1 and CAN2) while the third paleosol is near Pitigliano (PIT3). The development of CAN1, CAN2 and PIT3 occurred in different period intervals (13, 4 and 9 ka, respectively) on various pumice flow deposits of the Latera volcano. CAN1 showed a microporous structure filled by clusters of elongate phytoliths alongside concretions of Ti and Fe; large pumice fragments with signs of alteration and clay films were also observed. The A horizon of CAN2 showed large macropores and root channels filled by organic isotropic materials, while the mineral phase resulted moderately weathered (K-feldspars, pyroxenes, microcrystals of titaniferous magnetite, lava fragments). The lower pedogenic development of CAN2 vs CAN1 is confirmed by: i) higher Feo/Fed (0.37-0.43 vs 0.11-0.20) and lower Fed/Fet ratio (0.04-0.06 vs 0.11), ii) lower Alt/Sit (0.26-0.41 vs 0.42-0.50) and higher Alo-Alp/Sio. In the whole Canino sequence, the andic index (Alo+0.5 Feo) is always below 0.4%, indicating neither andic nor vitric properties, thus the soils do not meet the criteria for Andosols. In the more recent paleosol (PIT3), granular soil structure and high porosity, indicating an extensive biological activity, are associated with weakly weathered massive tuff fragments and primary minerals. In both A horizons, large amount of phytoliths were found as residues of root decomposition. In the Bw horizons, numerous anisotropic aureoles around microcrystals were observed, indicating the dissolution of Na-plagioclase. PIT3 showed andic index exceeding 0.4% in the Ab2 and Bw horizons, as well as lower contents of monovalent cations than CAN2, but similar Feo/Fed, Fed/Fet, Alt/Sit as CAN1. The pedogenesis of the three paleosols resulted well correlated with timing, but local conditions probably do not allow generalization on the climatic phases (MIS 8 - 7.4) effect on soils.

### 8.01 124518 - Assessing soil security

#### IS IT TIME TO CHANGE OUR THINKING ABOUT SOIL RADICALLY?

A. MCBRATNEY

The University of Sydney, Sydney, AUSTRALIA

For the sake of soil and its survival there are two aspects of thinking about it which require our attention and action urgently.

First, soil security is beginning to be recognised as a global existential challenge in its own right; and indeed as important as inter alia climate change, food security or biodiversity protection. In order to develop and disseminate that notion, which is beneficial to humanity, it is essential to take a soil-centric view. It is not enough simply to say that soil provides functions and services for other planetary and human existential purposes. Most importantly, soil is key to existence. Rather than criticising or downplaying it, we should advocate the soil-centric view with vigour and enthusiasm.

Secondly, we have developed soil science for over a hundred years and we are celebrating that dazzling century at this congress. To some degree a cursory view of soil security would imply soil with little to no human impact. Over the last thirty years we have begun to realise that the soil is finite as we have begun to run out of new areas to clear for cultivation. Principally, it is only over the the last decade we have finally realised that human forcings have begun to impact soil everywhere , not only in the places we have developed for agriculture. The realisation, that h humanity is fast becoming the most important soil-forming factor requires us to change our thinking substantially. The increase in temperature of soil profiles by at least 1C degree to depth all over the world, through human-induced climate change, will alter properties and increase the rate of soil processes everywhere. Are new genosols currently evolving? Should our soil classification systems recognise the impact of humanity everywhere rather than tacking it on the end as an anthroposol or technosol? What should be our reference soils and the implications for assessing soil security?

#### REVIEWING THE POLICY CONCERNS ON URBAN LAND SUBSIDENCE AND ITS RELATIONS TO URBAN SOIL QUALITY

M. LEE <sup>1</sup>, H. KIM <sup>1</sup>, J. YANG <sup>2</sup>

<sup>1</sup> Department of Geology, Kangwon National University, Chuncheon, SOUTH KOREA

<sup>2</sup> Department of Biological Environment, Kangwon National University, Chuncheon, SOUTH KOREA

Earth is composed of soil, water and air. Among which, soil provide ground to live on and food to eat. Yet, modernization progressed by exploiting soil as epitomized in how national development efforts mostly started with paved roads. It was not until an increasing number of road/land subsidence were reported in urban areas, where there is no distinctive karst terrain with carbonate bedrock or mines nearby, that shed lights on the principal role of soil as “the ground to live on.” As land subsidence accompanies both human and economic losses in urban areas, the incidents called for serious policy attention. Water flow change (lowered groundwater level or water pipe leakage) and softened soil (soil degradation) are noted as two main causes through the government investigations. Water flow change occurs 1) when large urban construction projects like metro line extension, mega-complex building interfere with groundwater nearby or 2) water leak from damaged water pipe in supply system. Such anthropogenic interference gradually forms cavity underground that may result in road/land subsidence when surface pressure exceeds the threshold point. A frequent urban construction processes, in which soil is disturbed, compacted, and damaged, further increases hazard risks. The cases review confirmed that more land subsidence cases were reported after heavy rain in such “softened” soil areas (where composition of sandy to fine-grained soil is high and the number of deeply rooted trees is minimal). The review, thus, concludes that the urban land subsidence should be approached in two-track: a continued effort to eliminate the fundamental cause of groundwater depletion and to enhance soil quality to strengthen the surface intensity. An effective precautionary measures would include: 1) a more frequent underground investigation in soft soil areas, 2) an increased minimum distance between high-rise buildings and underground constructions, 3) an effective groundwater resource management, 4) regular maintenance of the water supply pipelines, 5) an increased green spaces with more deeply rooted trees in urban areas.

<sup>2</sup> Universidade Federal de Viçosa, Viçosa, BRAZIL

Exploring the dynamics of land use land cover changes (LULCC) is essential to plan future landscapes that will reconcile the demand and maintenance of natural resources, contributing to reaching the targets of the Sustainable Development Goals. Therefore, decision-making guiding the governance of natural resources is directly linked to soil security. The present study explored spatiotemporal LULCC in an important river basin in Brazil (Rio Doce basin - RDB), where several challenges for its governance are strictly related to soil insecurity. We used LULC maps developed by the Brazilian MapBiomas project, which provides an annual time series of LULC maps from 1985 onwards and applied a pixel-by-pixel analysis to identify the presence/absence of LULCC, the modal classes of land use, as well as the variety and number of LULCC in 34 years of evaluation (1985 – 2018). Original RDB's vegetation, Brazilian Atlantic Forest, is a top priority hot spot for biodiversity conservation and restoration. Nonetheless, pasture and agriculture currently represent the main land uses, covering around 70% of RDB. Our results show a reduction of the natural forest (-1.9 % of the total area) and pastures (-9.1%), and an increase of monoculture tree plantations (+2,83 %). LULCC had spatial variation and 50% of the basin did not present LULC changes during the studied period, especially in pasture areas known for their degraded condition. Soil insecurity caused by a history of severe exploitation for agricultural purposes has led to deforestation and governance problems related to water, energy, and food security. Soil security approach can lead the way to these challenges.

<sup>1</sup> Research Centre for Agriculture and Environment, Council for Agricultural Research and Economics, Firenze, ITALY

<sup>2</sup> The National Institute of Horticultural Research, Skierniewice, POLAND

<sup>3</sup> Research Centre for Agriculture and Environment, Council for Agricultural Research and Economics, Roma, ITALY

<sup>4</sup> Institute of Environmental Biotechnology, Graz, AUSTRIA

Environmentally sustainable practices are needed for present and future agriculture. Upcoming progress in agriculture and the food system should provide solutions to challenges posed by climate change while simultaneously reducing their environmental footprint. The European Community is committed to pursue a reduction in the use of chemicals, that impact biodiversity and soil health.

One potential solution is represented by the application of formulated bioproducts containing beneficial microorganisms which can be released in the environment to promote plant growth by means of their bio-stimulant, bio-pesticide, and/or bio-fertilizer properties. Their use, already a widely adopted practice world-wide, represents a valid and cost efficient alternative to chemicals, deemed to grow in the coming years. However, we need to increase our knowledge on the biological processes determining their efficacy in the field, to further promote their use.

In this work we explored the bio-fertilizer and bio-pesticide potential of the *Paenibacillus polymyxa* K16 strain, isolated from tomato roots, for its pre-market characterization as a novel bioproduct. Whole genome sequencing was used to infer its functional potential. Its phenotypic characterization was performed by standard plate methods, by phenotype microarray (carbon, nitrogen, and phosphate/sulphur utilization), and by production of volatile organic compounds.

Results showed that the K16 strain has different bio-fertilizer (conversion of nitrate in ammonia; phosphorous solubilization; siderophore production) and bio-pesticide (plate antagonism; FusaricidinB and PolymyxinB gene; production of pyrazine volatile compound) potential functions, and low presence of antibiotic resistance genes. Phenotypic analysis showed highest activity on carbon sources (with a large fraction of non-utilized compounds), but more generalised activity on phosphate/sulphur compounds. The observed genes and measured metabolic activity were connected in metabolic pathways analysis, pinpointing the features of K16 strain for nitrogen and sulphur metabolism.

Overall, different approaches were successfully used to explore properties that a novel bioproduct should possess to survive and then exert a beneficial action on plant growth. Our approach can highlight a bioproducts' inherent stimulatory, fertilizing and bio-pesticide features.

#### ASSESSMENT OF PGP TRAITS OF BACTERIA ISOLATED FROM THE RHIZOSPHERE SOIL OF WILD MEDICINAL HERBS.

T. HAJNAL JAFARI, D. STAMENOV, S. DJURIC

Faculty of Agriculture, Department of Field and Vegetable Crops, University of Novi Sad, Novi Sad, SERBIA

Rhizosphere soil is rich in secondary metabolites and populated by numerous plant growth promoting (PGP) bacteria. They have different modes of action that could result in plant growth stimulation, such as nutrient availability improvement, control of pathogenic microorganisms, and production of plant hormones. Bacteria from genus *Azotobacter*, *Bacillus*, *Pseudomonas* and *Streptomyces* were isolated from the rhizosphere soil of six wild medicinal herbs, namely *Achillea mille folium* (yarrow), *Agrimonia Eupatoria* (agrimony), *Plantago lanceolata* (English plantain), *Mentha longifolia* (horse mint), *Stachys sylvatica* (hedge nettle), and *Centaurea Jacee* (brown knapweed). The main aim of this research was to assess the isolates PGP traits. Prior to that, morphological, physiological, and biochemical characterization were also performed. Out of total 36 bacterial isolates, 9 produced indole acetic acid (IAA), 10 demonstrated the ability to produce siderophores, and 27 were good producer of hydrogen cyanide (HCN). Significant number of isolates showed biostimulator potential, and the most important were *Pseudomonas* sp. K3/2 and K5/1, *Bacillus* sp. M3/1, *Azotobacter* sp. F1/2 and *Streptomyces* sp. S4/1. These isolates could serve as potential base in creation of a new microbe-based formulation.

**Keywords:** bacteria,growth promotion,rhizosphere,*Pseudomonas*,*Streptomyces*

### 8.02 133440 - Tailored microbiome-based solutions for a sustainable agriculture

#### ISOLATION AND CHARACTERIZATION OF BACTERIA FROM THE RHIZOSPHERE OF ECHINACEA (ECHINACEA PURPUREA L.)

D. STAMENOV, S. DJURIC, T. HAJNAL JAFARI

Faculty of Agriculture, University of Novi Sad, Novi Sad, SERBIA

This study aimed to isolate and characterize bacteria belonging to the genus *Azotobacter*, *Pseudomonas*, and *Bacillus* from the rhizosphere of *Echinacea* (*Echinacea purpurea* L.). The characterization involved physiological assessments (such as the growth of isolates at different temperatures, acidity levels, NaCl concentrations, resistance to Cd and Pb, and the use of various carbon sources), biochemical analyses (including the production of lipase, amylase, pectinase, gelatinase, protease, and cellulase), and the characterization of plant growth promoting activities (the production of indole-3-acetic acid (IAA), siderophores, hydrogen cyanide (HCN), mineralization and solubilization of phosphorus) of the isolates.

From the rhizosphere of *Echinacea*, two *Azotobacter* isolates (designated as A17 and A18), three *Pseudomonas* isolates (designated as P45, P46, P47), and three *Bacillus* isolates (designated as B86, B87, B88) were isolated. The *Azotobacter* isolates exhibited notable resilience, demonstrating viability under elevated temperatures, specifically at 37°C, and a broad pH range from 5 to 9. However, it was observed that a higher concentration of Cd inhibited the growth of *Azotobacter* isolates. Both isolates exhibited the capacity to utilize all examined carbon sources and produced pectinase, lipase, IAA, and HCN, while also utilizing organic and inorganic phosphorus.

*Pseudomonas* isolates exhibited optimal growth at 10°C, and on media with pH levels of 5, 7, and 9. All *Pseudomonas* isolates demonstrated the ability to produce pectinase, lipase, IAA, siderophores, and HCN. Notably, these isolates could utilize both organic and inorganic phosphorus sources.

In the case of *Bacillus* isolates, optimal growth at 37°C, and on media with pH levels of 7 and 9, were observed. These isolates utilized glucose and galactose as carbon sources and produced all tested enzymes, IAA, siderophores, and HCN. The *Bacillus* isolates could utilize both organic and inorganic phosphorus sources.

This comprehensive characterization provides valuable insights into the physiological and biochemical properties of these microbial strains, contributing to the broader understanding of the potential applications of PGP microorganisms in plant growth promotion.

*Pontoscolex corethrus*, a tropical and geophagous earthworm, is recognized for its beneficial impact on plant growth, due to its mutualistic relationship with soil microorganisms residing in its digestive tract or casts. These microorganisms are thought to play a fundamental role in key processes, such as nitrogen fixation and the production of plant growth substances, which are essential for a healthy interaction between the earthworms and plants. Despite this assumption, the specific influence of the gut microbiota of *P. corethrus* on such processes has not been definitively established. Therefore, our study aimed to explore the functional potential of the microbiota within the earthworm's gut and casts, particularly in its interaction with *Coffea arabica* and *C. canephora* plants. We observed variations in soil metabolism across the foregut, hindgut, and the casts of the worm, as well as the soil under the coffee species. LEfSe analysis was performed to determine enriched bacterial genera and Picrust2 to predict functional profiling of the microbiota in soil, foregut, hindgut, and cast. This analysis revealed enriched bacterial genera in each environment, particularly noting the presence of *Streptomyces* and *Bradyrhizobium* in the foregut and hindgut. *Bradyrhizobium* is recognized for its nitrogen-fixing ability, as well as some *Streptomyces* species. Additionally, *Micromonospora* was identified in association with these genera. Besides, the metabolic profiles of each compartment revealed unique compounds; specifically, 1H-indole-3-acetamide, precursor of indole-3-acetic acid, was tentatively identified exclusively in the foregut, and abscisic aldehyde, precursor of abscisic acid, was identified in the hindgut under both coffee species, among others. Thus, still need to be linked to which bacteria produce these metabolites. These observations emphasize the complexity of interactions and the role of earthworms in modulating bacterial composition and the metabolic profile of the gut content, as well as the probable nitrogen fixation in the soil. Our results provide new insights into the ecological role of *P. corethrus*, highlighting its contribution to soil dynamics and plant growth.

#### EFFECT OF COVER CROPS IN THE FERTILITY OF GALICIAN VINEYARD SOILS, NW SPAIN

P. PÉREZ-RODRÍGUEZ <sup>1</sup>, R. CUTILLAS-BARREIRO <sup>1,2</sup>, V. LALÍN-POUSA <sup>1,2</sup>, M. ARIAS-ESTÉVEZ <sup>1,2</sup>, D. FERNÁNDEZ-CALVIÑO <sup>1,2</sup>

<sup>1</sup> Department of Plant Biology and Soil Science, Area of Soil Science and Agricultural Chemistry, Faculty of Sciences, Ourense, SPAIN

<sup>2</sup> Agroecology and Food Institute (IAA), University of Vigo, Campus Auga, Ourense, SPAIN

The use of cover crops is a sustainable agricultural practice which aims at soil conservation, reducing soil erosion and loss of nutrients, and promoting soil life. This study implemented cover crops in vineyard soils to assess if they provide the necessary nutrients for the optimum vine growth, maintaining the soil fertility and allow reducing N-P-synthetic fertilizers. Three different treatments (by triplicate) were conducted at three sampling times throughout one cultivation cycle in five vineyards belonging to two Designation of Origin in NW Spain. Two different cover crops' incorporation methods were also tested: 9 surface or 36 buried cover plots. In total, 45 experimental plots have been analyzed obtaining 135 soil samples. The treatments were a) synthetic fertilizers-conventional dose, b) ½ dose-synthetic fertilizers + cover crops, c) only cover crops. Cover crops were a mix of legumes (*Vicia sativa*, 60%) and cereals (*Avena sativa* 10%, *Hordeum vulgare* 30%). Sampling times were at pre-seeding, spring and after mowing. Soil parameters analyzed were pH, EC, CEC, TC, TOC, macro- and micronutrients. A multifactorial statistical analysis was performed considering the three factors. As the interactions among them were not statistically significant, they were analyzed individually. Only the factor of time provided significant differences for Ca, Mg, Zn and CEC. This could be explained by the moment of sampling coinciding with different vines phenological stage, i.e., the second sampling time coincided with the moment of the greatest nutrient consumption. In addition, the parameters affected were secondary macro- and micronutrients, which are present in soil in lower concentrations, being more prone to changes. No differences among treatments and management indicated that all of them provided the same contents for soil fertility, resulting that cover crops maintained the same levels of nutrients than the synthetic fertilizers. This highlighted that the use of cover crops is a sustainable agricultural practice that may result a good alternative to traditional management in vineyards, allowing reducing the use of synthetic fertilizers.

#### THE INTERACTIVE EFFECTS OF ARBUSCULAR MYCORRHIZAL FUNGI AND RHIZOBACTERIA SYNERGISTICALLY ENHANCE MAIZE GROWTH BY IMPROVING NUTRIENT UPTAKE

Y. XU<sup>1</sup>, F. LIU<sup>2</sup>

<sup>1</sup> School of Ecology and Environmental Science, Yunnan University, Kunming, CHINA

<sup>2</sup> School of Agriculture, Yunnan University, Kunming, CHINA

Maize (*Zea mays* L.) is an important crop around the world. Symbiosis with arbuscular mycorrhizal fungi (AMF) is beneficial for maize to absorb nutrients from the soil. Evidence of the interactions between AMF and soil bacteria suggests that their combined function is important in promoting soil nutrient uptake. To evaluate the effects of AMF on the bacterial community in the rhizosphere of maize, we conducted greenhouse experiments with and without AMF inoculation. Here, we first examined the response of bacteria in the rhizosphere of maize roots to AMF inoculation by 16S rRNA gene amplicon sequencing and metagenomic sequencing. Then we explored the synergistic functions between rhizosphere bacteria and AMF through synthetic community and maize plant inoculation experiments. AMF significantly increased maize biomass and nitrogen (N), phosphorus (P) and potassium (K) concentrations. Based on 16S rRNA gene amplicon sequencing and metagenomic sequencing, we found that five core bacterial genera, including *Pseudomonas*, *Methylothermobacter*, *Flavisolibacter*, *Methylophilus*, and *Rhodococcus*, were consistently enriched in the rhizosphere of maize inoculated with AMF. The five core bacterial genera were positively correlated with maize biomass and concentrations of N, P, and K. We isolated *Pseudomonas*, *Flavisolibacter*, and *Rhodococcus* from the rhizosphere of AMF-colonized maize and identified their function in N, P, or K metabolism. Further inoculated experiments from the synthetic community revealed that AMF and these strains synergistically enhanced maize growth and promoted NPK uptake. The cooperation between AMF and the core rhizosphere bacteria attracted by mycorrhizae significantly promotes maize growth. Our findings indicate that the synergistic effect between AMF and rhizosphere bacteria may stimulate the release of soil NPK and increase the nutrient transfer to host plants. This study provides a way to exploit AMF and bacteria interactions to overcome soil nutrient deficiencies in sustainable agriculture.

**Keywords:** Arbuscular mycorrhizal fungi, nutrient uptake, maize, rhizosphere bacteria

#### RESPONSE OF SOIL GROSS NITROGEN MINERALIZATION TO FERTILIZATION PRACTICES IN CHINA'S UPLANDS

J. WANG, Q. XIAO, L. WU, Y. HUANG, W. ZHANG

Institute of Agricultural Resources and Regional Planning, Beijing, CHINA

Improving soil nitrogen (N) supply capacity is recognized as a viable solution for sustaining cereal production for food security, since more than half of N absorbed by crops comes from the soil through the gross N mineralization (GNM) process. However, significant uncertainties exist regarding GNM patterns driven by commonly used fertilization practices in croplands. Based on soils collected from 13 long-term fertilization trials spanning over 30 years across China's uplands by using the  $^{15}\text{N}$  dilution technique, we found that manure application led to the highest stimulation of GNM (188.7-966.1%), followed by straw (75.5-472.8%) and chemical fertilizer (6.7-389.1%), compared to unfertilized treatment. Fertilization-induced GNM changes were primarily influenced by the initial soil pH in the chemical fertilizers and straw treatments, and by soil clay content in the manure treatment. The structural equation model identified that the increases in soil pH and clay content indirectly promoted GNM by enhancing soil properties (e.g. total dissolved N) and associated microbial attributes (e.g. N-acquiring enzyme activity, bacterial and fungal biomass). These findings underscore the potential of prioritizing chemical fertilization and straw applications in high pH soils, and manure in heavier texture soils, to maximize soil N supply. This knowledge is crucial for developing policies aimed at reducing N fertilizer use and N losses in China.

**SILICON FERTILIZATION ENHANCES PHOTOSYNTHETIC PIGMENTS CONTENTS, PHOTOSYNTHESIS RATE, AND YIELD OF SOYBEANS IN CONTRASTING SOILS**

M. SARTORI DE CAMARGO<sup>1</sup>, T. LAVIAGUERRE LAND<sup>1</sup>, H. LUIZ SANTOS<sup>2</sup>, M. DE ALMEIDA SILVA<sup>2</sup>

<sup>1</sup> Agencia Paulista de Tecnologia dos Agronegocios (APTA), APTA Regional, Piracicaba, SP, BRAZIL

<sup>2</sup> Universidade Estadual Paulista, Faculdade de Ciências Agrônômicas, Departamento de Produção Vegetal, Botucatu, SP, BRAZIL

Studies about silicon (Si) fertilization are scarce in no-Si accumulator plants such as soybeans, especially on the association between Si uptake and Si availability in soils without stress conditions. This study evaluated whether Si rates applied in contrasting soils increase Si availability in soils, Si uptake by leaves, biomass, and pod yield, and enhance physiological aspects of soybean. The experiment was conducted in pots (100 L) in a completely randomized factorial scheme with 4 Si rates (0, 250, 500, 750 kg ha<sup>-1</sup> Si), 3 soils: Quartzipsamment (RQ), Rhodic Hapludox (LV) and Rhodic Acrudox (LVdf), and 4 repetitions from November/22 to March/23 at Piracicaba, SP, Brazil. Ca-Mg silicate was used as a Si source. All plots received the same quantities of Ca, and Mg using lime and/or MgCl<sub>2</sub> when necessary. Net CO<sub>2</sub> assimilation rate (A), plant transpiration (E), stomatal conductance (gs) and electron transport rate (ETR), relative water content (RWC), chlorophyll a, and b (Chla, Chlb), carotenoids, and Si concentrations were evaluated in the 2nd trifoliolate leaves, and dry biomass of pods (P) and stem+leaf (AP) in the phase R8. Soluble Si in 0.01 CaCl<sub>2</sub> mol L<sup>-1</sup> was determined in soils. ETR and gs were only influenced by soils. The rates of Si (Y) increased only Chla ( $Y=0.009X + 53.339$ ,  $R^2=0.70^*$ ), carotenoids ( $Y=0.003X + 14.180$ ,  $R^2=0.79^*$ ), RWC ( $Y=0.008X+66,8$ ,  $R^2=0.78^*$ ), Si in leaves ( $Y=0.003X+3.637$ ,  $R^2=0.95^*$ ), independently of soil, and soluble Si of RQ ( $Y=0.006X+3.837$ ,  $R^2=0.89^*$ ), LV ( $Y=0.012X+4.667$ ,  $R^2=0.93^*$ ), and LVdf ( $Y=0.014X+7.425$ ,  $R^2=0.95^*$ ). The maximum A, and dry biomass of pods were obtained with 560, and 470 kg ha<sup>-1</sup> Si, respectively (Fig 1). The dry biomass of AP was increased with Si rates for RQ, and maximum values were shown with 430, and 512 kg ha<sup>-1</sup> Si for LV, and LVdf (Fig 1). It was concluded that increased Si rates enhance photosynthetic pigments, photosynthesis rate, and pod and biomass yield in soils with different Si availability. (Financial support: FAPESP 22/0073307).

#### CHANGES IN SOIL CHEMICAL PROPERTIES AND GREENHOUSE GAS EMISSIONS FROM PADDY SOILS AFTER ONE YEAR OF RICE HUSK BIOCHAR APPLICATION WITH OR WITHOUT ORGANIC MANURES

W.W. MON<sup>1</sup>, Y. TOMA<sup>2</sup>, H. UENO<sup>1</sup>

<sup>1</sup> Department of Bioresource Production Science, United Graduate School of Agricultural Sciences, Ehime University, Matsuyama, JAPAN

<sup>2</sup> Department of Agro-Biological Science, Graduate School of Agriculture, Hokkaido University, Sapporo, JAPAN

The issue of increasing greenhouse gas emissions (GHGs) from rice cultivation has gained attention in recent decades. Therefore, mitigation techniques such as enhanced manure management, improved nitrogen use efficiency, and better agricultural practices must be considered to enhance agricultural production without increasing GHGs emissions. Hence, a precise pot experiment was conducted with medium- and low-fertility soils to determine the changes in the chemical properties of paddy rice soil and N<sub>2</sub>O and CH<sub>4</sub> emissions after one year of rice husk biochar (RHB) application.

Pot experiment was conducted under greenhouse conditions from June 2023 to September 2023 at Ehime University, Japan. There were seven treatments with three replications in both soils: (1) C= control (without RHB), (2) B5= RHB 5 t ha<sup>-1</sup>, (3) B10= RHB 10 t ha<sup>-1</sup>, (4) B5: CHM= RHB 5 t ha<sup>-1</sup> + chicken manure 5 t ha<sup>-1</sup>, (5) B5: COM= RHB 5 t ha<sup>-1</sup> + cow manure 5 t ha<sup>-1</sup>, (6) B10: CHM= RHB 10 t ha<sup>-1</sup> + chicken manure 5 t ha<sup>-1</sup> and (7) B10: COM= RHB 10 t ha<sup>-1</sup> + cow manure 5 t ha<sup>-1</sup>. The soil was amended with biochar and organic manures on the 6th of June 2022, and rice was cultivated. The results indicated that the highest grain yield was obtained by the application of B10: CHM, followed by B5: CHM and B10, through improving soil exchangeable K, available P, and soil EC in both soils. Even though B10: CHM obtained the maximum yield and significantly suppressed N<sub>2</sub>O emissions, the highest CH<sub>4</sub> emissions were recorded in this combination for both soils. CH<sub>4</sub> emission from B5:CHM application was not significant compared to the lowest emissions of B5 and B10 in medium-fertility soil and low-fertility soil. Overall, application of B5:CHM is acceptable to improve soil chemical properties and grain yield simultaneously without increasing GHGs, regardless of soil fertility.

#### IS CONTROLLED-RELEASE N FERTILIZER USE FOR CORN A WORTHWHILE STRATEGY?

K.P. FABRIZZI<sup>1</sup>, F.G. FERNANDEZ<sup>1</sup>, J.A. VETSCH<sup>2</sup>, W.F. LAZARUS<sup>3</sup>

<sup>1</sup> University of Minnesota-Department of Soil, Water, and Climate, St. Paul, USA

<sup>2</sup> University of Minnesota- Southern Research and Outreach Center, Waseca, USA

<sup>3</sup> University of Minnesota-Department of Applied Economics, St. Paul, USA

Managing N for corn production is a key to minimizing N losses. Excessively wet spring conditions resulting from ongoing climate change exacerbate loss potential of early spring N applications. Also, a shift in available N fertilizer sources calls for an extensive evaluation of these sources across different soil conditions to update the current N best management practices. The objectives of this research are to evaluate various urea, polymer-coated urea (PCU), and PCU-urea blends and N application timing strategies in corn production and determine the agronomic and economic optimum N rate and grain yield, N use efficiency and indirectly the potential for N loss to the environment, and their cost-benefit relationship. N sources and application time were evaluated in a 3yr study in sandy (irrigated) and fine-textured soils under corn-soybean rotation at the Research and Outreach centers (ROCs) in Waseca, Lamberton, Becker and Rosemount, MN. Grain yield, the economic optimum N rate (EONR), net return, and N use efficiency were determined at each site/year. An in-situ incubation of PCU fertilizer was performed at all sites. Residual inorganic soil N was measured at post-harvest. For the fine-textured soils, grain yield was significantly affected by N source in only 2 of 3 years at Waseca with no differences at Lamberton. However, the use of PCU-Urea blends resulted in lower EONRs than Urea or PCU in fine-textured soils for the 3 growing seasons, and PCU had lower EONRs than Urea in 2023 at Lamberton. In sandy soils, grain yield was significantly affected by N source only in Rosemount 2021. Also, the split application of PCU-Urea blend had lower EONR but not necessarily greater economic net return than Urea in these sandy soils.

#### ROCK DUST AS A NATURAL SOURCE OF POTASSIUM IN FILTER CAKE COMPOSTING

L. LOBO DE GODOI <sup>1</sup>, J. WILLIAN MOREIRA <sup>2</sup>, D. LIMA CAVALCANTE MARINHO <sup>2</sup>, W. MOZENA LEANDRO <sup>2</sup>, P. BATISTA PASSOS <sup>2</sup>, M. PORTO MUNIZ <sup>2</sup>, J. VILELA DE CASTRO <sup>2</sup>

<sup>1</sup> Legislative Assembly of the State of Goiás - Environment and Water Resources Committee; Federal University of Goiás., GOIÂNIA, BRAZIL

<sup>2</sup> Federal University of Goiás (UFG), School of Agronomy, Department of Soils., GOIÂNIA, BRAZIL

In the process of producing ethanol, a biofuel made from sugar cane, large quantities of the organic waste 'filter cake' are generated, which after composting is used as an organic fertilizer. The addition of rock dust, phonolite, to this biological process can increase the content of the nutrient potassium. Originating from silicate rocks, phonolite is a natural source of potassium, with a total content of 8% K<sub>2</sub>O and 1% K<sub>2</sub>O soluble in 2% citric acid. The aim of this study was to determine the potassium content of filter cake enriched with rock dust, phonolite, as a function of composting time. The experiment was conducted at the Biomass and Biogas Laboratory of the School of Agronomy of the Federal University of Goiás – UFG - Brazil. The treatments consisted of adding 0%, 1% and 5% rock dust to 200g samples of filter cake, packed in polyethylene bags, with different composting days: T0-0 days - raw filter cake, T1-10 days, T2-90 days, T3 - humified compost. For analysis, 3g of each treatment was added to 60ml syringes with a tube attached. 50ml of deionized water was applied to check the K content using the Mehlich-1 method. The results showed that at 10 days of composting, the highest K content was 270 mg.kg<sup>-1</sup> with the 1% rock dust dosage. At 30 days of composting, the highest content was observed at 1% rock dust, 700 mg.kg<sup>-1</sup>. After 90 days of composting, the highest K content was observed in the treatment with 0% added K, with approximately 820 mg.kg<sup>-1</sup>, a result that may be related to the natural solubilization of the compost. The highest potassium release was observed with the 1% dosage of rock dust, which reached 900 mg.kg<sup>-1</sup>. The use of rock dust can be an alternative and sustainable source of potassium to improve the quality of composts and soils.

<sup>2</sup> Nanjing Forestry University, Nanjing, CHINA

<sup>3</sup> Fujian Academy of Agricultural Sciences, Fuzhou, CHINA

<sup>4</sup> Nanjing Agricultural University, Nanjing, CHINA

<sup>5</sup> Jinling Institute of Technology, Nanjing, CHINA

Soil health has been described as the ability of soils to sustain productivity, diversity, and environmental services of terrestrial ecosystem. As one of the essential macronutrients, potassium (K) affects soil health, and is mandatory for agricultural productivity. Fertilization is necessary for expanding soil K stocks and attaining higher plant yield. Crop straw return and organic manure application are effective and environmentally friendly methods used by farmers to improve soil structure, fertility and agricultural productivity. Sweet potato is a typical K-favoring food crop and widely grown throughout the world. However, the regulation effects of long-term organic fertilization on soil aggregates-associated K stocks and K uptake by sweet potato are less understood. Herein, a long-term fertilization experiment under peanut-sweet potato crop rotation established since 2007 including chemical fertilizer (NPK), NPK combined with commercial manure (NPK+CM), NPK combined with pig manure (NPK+PM), and NPK combined with rice straw (NPK+RS) treatments under peanut-sweet potato crop rotation was employed to further comprehend the effects of organic fertilizers application on soil aggregates-associated total potassium (TK), exchangeable potassium (EK), non-exchangeable potassium (NEK) stocks, and explore the contribution of aggregates-associated K stocks to the generation of K uptake and yield of sweet potato. Result showed that long-term fertilizer application contributed to higher yield, yield stability, and K uptake of sweet potato. NPK+PM and NPK+RS treatments both showed the best promoting effect on plant growth. NPK+PM and NPK+RS treatments showed remarkable increasement of aggregate-associated EK and NEK stocks, particularly for small-macroaggregates (0.25–2 mm) and large-macroaggregates (> 2 mm). TK, EK and NEK stocks in large and small-macroaggregates displayed positive effects on K uptake and yield for sweet potato. Pearson's correlation and random forest model analysis revealed that EK and NEK stock in large-macroaggregate were the most key factors for K uptake and yield of sweet potato under long-term fertilization. Overall, this study helps to clarify the prominent advantage of long-term fertilization with chemical fertilizers combined with organic fertilizers.

#### EFFECTS OF NPK FERTILIZATION ON GROWTH AND YIELD OF 'GODEULPPAEGI' (CREPIDIASTRUM SONCHIFOLIUM)

J.S. LEE, J.I. LEE, Y.G. CHO, J.I. JU, Y.U. YUN

Chungcheongnam-do Agricultural Research and Extension Service Institute, Yesan, SOUTH KOREA

In order to reduce the environmental load caused by agricultural activities, such as excessive soil nutrient input, Korea government is implementing a public direct payment system that provides subsidies to farmers who use chemical fertilizers in accordance with fertilizer application standards. So far, fertilizer application standards for 104 major crops have been established, and it is necessary for other minor crops grown in Korea.

This study was carried out to establish fertilizer application standard for 'Godeulppaegi', which has no standard, Yields and responses of 'Godeulppaegi' were evaluated in different level of NPK fertilization. N, P<sub>2</sub>O<sub>5</sub>, and K<sub>2</sub>O fertilizer were applied at 0, 50, 100, 150, and 200% of the practical fertilization amount (N-P<sub>2</sub>O<sub>5</sub>-K<sub>2</sub>O = 60-44-43 kg ha<sup>-1</sup>), respectively. In the N treatments, yield were the highest at N 100% treatment, and decreased with further increases in N rate. For P treatments, root growth, leaf width and weight were tended to increase with P<sub>2</sub>O<sub>5</sub> fertilizer amount, but yield was the highest at P 150% treatment and decreased with further increases in P<sub>2</sub>O<sub>5</sub> rate. In the K treatments, yield was the highest at K 100% treatment and decreased with further increases in K<sub>2</sub>O rate. By the regression equation between the amount of NPK fertilizer application and yield, the highest yields were obtained with the application of 91-65-37 kg ha<sup>-1</sup> as N-P<sub>2</sub>O<sub>5</sub>-K<sub>2</sub>O, respectively.

**Keywords:** 'Godeulppaegi', Fertilization, NPK

#### A NEW FRAMEWORK TO MODEL THE DISTRIBUTED TRANSFER AND RETENTION OF NUTRIENTS BY INCORPORATING TOPOLOGY STRUCTURE OF SMALL WATER BODIES

Y. XIA

Institute of Soil Science, Chinese Academy of Sciences, Nanjing, CHINA

Small water bodies such as interval water-flooded ditches, ponds, and streams serve as important nutrient sinks in many landscapes, especially in the multi-water continuum system. Yet watershed nutrient cycling models often fail to or insufficiently capture these waters, resulting in great uncertainty in quantifying the distributed transfer and retention of nutrients across diverse landscapes in a watershed. In this study, we present a network-based predictive framework of the nutrient transport process in nested small water bodies, which incorporates topology structure, hydrological and biogeochemical processes, and connectivity to perform a nonlinear and distributed scaling of nutrient transfer and retention. The framework was validated and applied to N transport in a multi-water continuum watershed in the Yangtze River basin. We show that the importance of N loading and retention depends on the spatial context of grid source and water bodies because of the great variation in location, connectivity, and water types. Our results demonstrate that hotspots in nutrient loading and retention could be accurately and efficiently identified through hierarchical network effects and spatial interactions. This offers an effective approach for the reduction of watershed-scale nutrient loads. This framework can be used in modeling to identify where and how to restore small water bodies for reduced non-point pollution from agricultural watersheds.

#### FERTILIZATION MANAGEMENT IMPACTS ON GREENHOUSE GASES (GHGs) EMISSIONS FROM A CASPICUM ANNUUM L. CROPPING SYSTEM

L. VITALE<sup>1</sup>, A. MANCO<sup>1</sup>, A. TEDESCHI<sup>2</sup>, V. MAGLIULO<sup>1</sup>

<sup>1</sup> ISAFOM-CNR, Naples, ITALY

<sup>2</sup> IBBR-CNR, Naples, ITALY

Arable soils contribute in a significant way to greenhouse gases (GHGs) emissions in the atmosphere through CO<sub>2</sub> and N<sub>2</sub>O emissions due the massive use of N-based fertilizers and soil management. CO<sub>2</sub> formation is mainly related to soil heterotrophic microbial respiration and autotrophic plant root respiration. N<sub>2</sub>O formation into the soil is mainly due to nitrification and denitrification processes, influenced by soil moisture, temperature, oxygen concentration, pH, and carbon and nitrogen content. Crop management, in particular fertilization, can affect nutrient use efficiency (NUE) and GHGs emissions. Compared to the traditional soil fertilization, fertigation allows applying nutrients through an irrigation system, synchronizing nutrient supply and crop requirement, improving water and nutrient use efficiency while decreasing leached N and fertilizer-induced N<sub>2</sub>O emissions from soil. In this work, we monitored CO<sub>2</sub> and N<sub>2</sub>O emissions from a Caspicum annuum L. cropping system located in Southern Italy, using an automated chambers system connected to a GHGs analyser. We measured CO<sub>2</sub> and N<sub>2</sub>O soil fluxes from June 30th to September 22nd, comparing fluxes from fertigated plots with those emitted by plots with granular fertilization. We designed the experimentation with five different treatments: zero thesis with any fertilization applied; granular fertilization with two different nitrogen level, named G70 and G100, respectively with 70% and 100% of crop nitrogen requirement; fertigation with two different nitrogen level, named F70 and F100, respectively with 70% and 100% of crop nitrogen requirement. Preliminary results indicate that fertigation led to slightly lesser N<sub>2</sub>O emissions, even though greater benefits are expected when adopting higher frequency of watering. However, interactions with the main environmental drivers – soil temperature and moisture, crop biomass and leaf area, soil and plant nutrient contents, days from irrigation and fertilization – should better quantify meaningful relationships. Cumulate N<sub>2</sub>O fluxes have been affected by N levels whereas the yield-scaled N<sub>2</sub>O emissions have been lower for the higher N dose irrespective of fertilization type.

#### BIO-BASED AND TRADITIONAL FERTILIZATION STRATEGIES IN TWO DIFFERENT SOILS

S. SOCCIARELLI<sup>1</sup>, C. BENI<sup>2</sup>, U. NERI<sup>1</sup>, C. FONTANA<sup>1</sup>, R. AROMOLO<sup>1</sup>, G. CORTI<sup>1</sup>

<sup>1</sup> CREA - Council for Agricultural Research and Economics, Research Centre for Agriculture and Environment, Rome, ITALY

<sup>2</sup> CREA - Council for Agricultural Research and Economics, Research Centre for Engineering and Agro-Food Processing, Monterotondo (Rome), ITALY

A bio-based fertilizer called Pellet, derived from centrifugation of patè olive cake (POC), a new peculiar solid olive mill waste, was evaluated as soil amendment.

The research was conducted at an experimental farm located near Rome, inside a tunnel, in microcosms (7 kg of soil). Two soils (H and AP) different in pH, limestone content and TOC were chosen, taking the arable layer (0-0.3 m depth). The H soil, Eutric Cambisol with sub-acid pH (6.4) was sampled on a volcanic hilly area, the AP soil, a Calcaric Cambisol with sub-alkaline pH (7.5) on an alluvial plain area.

Fertilizers based on raw Pellet or Pellet with binary fertilizer addition (NP) was compared to organo-mineral and ternary mineral (NPK) fertilizers. A control thesis without treatments was considered. Both soils and Pellet were characterized.

Lettuce (*Lactuca sativa* L., Salad bowl type) is the most important leafy vegetable, grown at various times of the year and in different climatic environments. It was chosen for its rapid growth and grown for 7 weeks. The following parameters were evaluated on lettuce: fresh and dry weight, height, SPAD, N content.

The results obtained were analyzed using ANOVA.

Notably, the difference between the two soils is always significant for all measured parameters. In AP soil, treatments with raw Pellet and Pellet with NP integration given the best responses in terms of biomass yield, SPAD and nitrogen content, compared to the treatments with traditional fertilizers. On the contrary, H soil showed lower biomass yield and N content compared to the mineral fertilizers and the control. This could be due to nitrogen immobilization processes, not excluding possible toxic effects due to the high phenol content of Pellet.

Our preliminary results seems to indicate that Pellet could be effectively used as an amendment on alkaline soils, while the use on acidic soils must be carefully evaluated.

<sup>2</sup> Department of Agriculture, Food, Environment and Forestry (DAGRI), University of Florence, Florence, ITALY

<sup>3</sup> Department of Agronomy, Food, Natural Resources, Animal and Environments (DAFNAE), University of Padoa, Padoa, ITALY

World population is increasing by almost 33% since 2019 and agricultural production will need to increase without compromising environment and food quality. In this scenario, the development of efficient, prompt and sustainable fertilization practice could be a valid support for crop productivity. The synthetic urea-based fertilizers are wide used, but the fertilization can determine environmental impacts, as nitrate contamination of groundwater and GHGs and ammonia emission. The use of "smart" fertilizers, by controlled N release, is an option to enhance N use efficiency, and decrease environmental pollution.

The purpose of CONTROL FERT project is to provide a sustainable approach to nutrient management, as required by Integrated Nutrient Management Action Plan of EU, developing, and testing new urea formulations, single and/or multilayer urea grains modified with the addition of urease and/or nitrification organic inhibitors. Preliminary test at laboratory conditions to verify N release, nitrification and urease inhibition in soil and ecotoxicity of smart fertilizers were performed. Two different soils during 14 days of incubation of prototypes were analyzed. In the laboratory experiment, fertilization rate was in accordance with the N dose used in open field. Unfertilized soil, with conventional urea and with already marketable smart urea (NBPT) was considered as controls. The urea-based smart fertilizers showed inhibition trend of nitrification and urease activity during 14 days of incubation in soil. The chemical composition and the structure of smart fertilizers affected their efficiency.

Ecotoxicological tests were performed to verify the absence of environmental hazard of smart urea prototypes in the soil.

The preliminary validation has allowed to test smart fertilizers prototypes in real farming conditions, giving reliable results and producing prototypes characterized by high TRL.

#### IMPROVEMENT OF SOIL PROTECTION AND CROP NUTRIENT SUPPLY IN BLUEBERRY PLANTATIONS IN WESTERN GEORGIA

G. GHAMBASHIDZE<sup>1</sup>, L. TSIVILASHVILI<sup>1</sup>, M. BURJANADZE<sup>2</sup>, T. TSETSKHLADZE<sup>1</sup>, N. KHARABADZE<sup>2</sup>

<sup>1</sup> Scientific-Research Centre of Agriculture, Soil Fertility Research Service, TBILISI, GEORGIA

<sup>2</sup> Agricultural University of Georgia, TBILISI, GEORGIA

The study was conducted in Western lowlands of Georgia to assess soil fertility status and nutrient supply of blueberry plantations on acid soils under humid subtropical climate conditions. The blueberry cultivation does not have long history in Georgia; therefore, elaboration of sustainable soil management practices is essential for its profitable cultivation. Low pH and high precipitation rate require precise selection and application of fertilizers to minimize losses, but at the same time ensure adequate supply of nutrients to plants.

Soil nutrients status varied greatly among studied plantations, which directly related to existing soil management practices, plot's location and topography and also its historical use. One of the reasons of decline in soil nutrients content was soil water erosion on the slopes accelerating soil losses in the past, as after removal of previous crops arable lands often were abandoned for certain period of time. Currently, such eroded parts of the studied plots can be easily observed with removed topsoil and nutrient deficiency symptoms on blueberry plants, which was proved by soil and plant leaf nutrient status. We have tested several soil management practices including incorporation of cover crops and straw mulching, which protects soil from erosion, and supports organic matter build up in soil and regulates water and temperature in the root zone.

**Keywords:** soil nutrients, soil erosion, cover crops, mulching, blueberry

<sup>4</sup> Division of Agronomy, Department of Crop Sciences, BOKU, Vienna, AUSTRIA

Due to natural and androgenic activities, a high concentration of arsenic (As) in the environment is linked to numerous ecological and health issues. The mobilisation, transportation, sorption and sequestration of As, especially in the soil, is strongly influenced by the availability of phosphorus (P) due to their shared chemical properties between As and P. Liberation or release of soil As often occurs due to the competition of sorption sites which often result in the mobilisation less toxic form of As i.e arsenate (As(V)). On the other hand, other prevailing environmental variables such as pH, organic materials (OM), redox potential (Eh), microorganisms, among others, facilitate the transformation of the readily available As(V) to mobile and more toxic As species i.e. As(III). This process promotes the availability of toxic environmental As and increases the chance of As phytotoxicity to the surrounding plant; Thus, it increases the potential of As toxicity along with the trophic level. In this article, we examine the significant role of P availability or fertilisation in mobilising As and its link to the proliferation of numerous environmental, agricultural, and public health issues. We also explore some advanced analytical techniques for analysing the As-P interaction in different environmental samples and suggest further research direction that will support the quest for sustainable, eco-friendly approaches to the As pollution in the environment.

**FERTILITY AND QUALITY OF SOILS AND HEALTH OF COFFEE PLANTATIONS IN FILOMENO MATA,  
INDIGENOUS REGION OF TOTONACAPAN, VERACRUZ, MEXICO**

R. ÁLVAREZ HERNÁNDEZ, M. GALÁN RESENDIZ

Universidad Autónoma Chapingo, TEXCOCO, MEXICO

Mexico is 6th place in world coffee production, 685,000 hectares planted in Chiapas, Oaxaca, Veracruz and Puebla, with 98% of the production. Until 2010, coffee was the third source of foreign exchange for the country (42% of exports); 280 thousand families depend on its cultivation. Coffee-growing areas occupy 12 states, 400 municipalities and 3,500 communities, from 250-1,500 MASL, which, together with low luminosity, cool temperature and sufficient precipitation, favor fruiting, growth and quality. The municipal coffee area is 558 ha with 1,721.60 t of coffee cherry. The soils are of volcanic origin. For better development of the coffee tree, they must have a depth of 1 meter, a loamy texture with clay crumbs, OM > 7%, pH of 4.5-5.5. In the area, the geology is sedimentary and limestone-shale rocks dominate (82%), igneous-extrusive rocks and basalts 10%. The soils are calcareous, steep, clayey, adhesive, and difficult to work, low infiltration, permeability & drainage, slightly acidic pH, high CEC and BCSR: Leptosols-84%, Regosols-8%, Acrisols-5% and Cambisols-1%. There is a deficit of N, K and little P and B due to excess Ca. Fe is abundant. There is slow decomposition of organic matter and nutritional imbalance. The foliar analysis indicates a deficit in N, Ca and other nutrients. The main variable relationships are Mg-Zn, Cu-OM, CEC-Ca, pH-N, Na-CE, Mn-B & Ca vs B-P. The (+) soil quality factors are structure and depth and (-) erosion and residue status. The (+) health factors of coffee are resistance to stress and plant diversity on farms and (-) yield and growth of coffee. There is little use of chemical inputs. Vegetable waste and organic fertilizers are recycled. Commercial polyculture and agroecological strategies is a sustainable productive strategy for small coffee growers.

#### CROP RESIDUE CONTRIBUTIONS TO PHOSPHORUS DYNAMICS AND POTENTIAL BIO-AVAILABILITY IN A VOLCANIC SOIL OF CENTRAL MEXICO

J.S. BAYUELO JIMENEZ<sup>1</sup>, D. TINOCO VARELA<sup>2</sup>, O. HERNÁNDEZ LARA<sup>3</sup>

<sup>1</sup> Universidad Michoacana de San Nicolás de Hidalgo, MORELIA, MEXICO

<sup>2</sup> Universidad Michoacana de San Nicolás de Hidalgo, MORELIA, MEXICO

<sup>3</sup> Instituto de Suelos, Ministerio de Agricultura, Habana, CUBA

Phosphorus (P) deficiency is a significant challenge for agricultural productivity on many highly P-sorbing temperate soils in central Mexico. For these soils, a continuous addition of water-soluble P fertilizers is required. However, water-soluble P can be retained by Fe, Al and Ca and is virtually unavailable to most plant species. The resulting low P- efficiency, coupled with rapidly rising cost of fertilizers, has increased interest in biological cycling of P sources as crop residues. To assess the longer term effects of residue addition on soil P fractions, we added residues from bean, sorghum and avocado to an acidic soil and measured the concentrations of P forms over three months. The size of various P forms was assessed by sequential P fractionation on days 1, 45 and 90. Compared to unamended control, addition of bean and sorghum residues increased the concentrations of resin P, microbial P, Bic Pi, NaHCO<sub>3</sub> -Pi, and NaOH0.1 -Pi temporarily whereas amendment with avocado residues had little effect on P form concentrations. The decrease in NaHCO<sub>3</sub> -Po and NaOH Po towards the end of experiment coincided with an increase in NaHCO<sub>3</sub> Pi and NaOH0.1 -Pi. Microbial biomass after crop residue additions was positively related to NaOH-Pi and decreased with soil depth. This results indicate that at least some of the NaOH -Pi may be biologically available within a relatively short time (days to weeks). The concentration of various P pools was strongly affected by the properties of the residues. Residues with high total P and low C:P ratio resulted in P mineralization in the microbial biomass. Addition of low C:P residues on the other hand, may not result in high amounts of immediately available P, but the P supply is more sustained due to P release from decomposing residues and turnover of microbial biomass P.

### 8.05 133606 - Life, agriculture, and productive systems in soils from Arctic, Antarctic and other cold regions

#### THE RHIZOSPHERE OF *SILENE ACAULIS* IN WESTERN GREENLAND: SOIL CARBON DYNAMICS AND MICROBIAL DIVERSITY

M.C. MOSCATELLI<sup>1</sup>, F. CANINI<sup>2</sup>, R. MARABOTTINI<sup>1</sup>, S. MARINARI<sup>1</sup>, C. CARUSO<sup>2</sup>, L. BERTINI<sup>2</sup>

<sup>1</sup> Dept. for Innovation in Biological, Agro-food and Forest systems, University of Tuscia, Viterbo, ITALY

<sup>2</sup> Dept. of Ecological and Biological Sciences, University of Tuscia, Viterbo, ITALY

Polar regions offer a unique opportunity to test biogeographic patterns of microbial taxonomic and functional diversity, providing indications of the future consequences of environmental change. Arctic islands and the Antarctic continent are characterised by protracted low temperatures, limited freshwater availability, seasonally dependent light conditions and restricted nutrient availability. Polar regions are facing increasing temperatures faster than elsewhere in the world due to polar amplification, challenging the native organisms which often live at their physiological limits. *S. acaulis* is a cushion plant playing a key role in alpine/arctic ecosystems as facilitator species and nurse plant also determining the resilience of high-latitude ecosystems to global climate change.

The present study was performed in Greenland at: Kobbefjord, Nuuk, West Greenland (64°10'36"N, 51°31'37"W) and Disko Island, Baffin Bay, off the west coast (69°44'59.99"N, 53°39'59.99"W). At Kobbefjord two sites were selected: site KA at 77 m asl and site KB at 60 m asl, 700 and 400 m from the sea, respectively. Also, three sites were selected at Disko Island: site DIA at 8 m asl, site DIB at 25 m asl, and site DIC at 81 m asl at 100, 600 and 1000 m from the sea, respectively. Permafrost is randomly present at Disko Island but not at Kobbefjord.

Soil physical (texture), chemical (total organic C, total N, inorganic N, pH, extractable C) and biochemical (microbial biomass, microbial respiration, enzymatic activities and functional diversity) properties as well as fungal community diversity and composition (DNA metabarcoding) were assessed in *S. acaulis* rhizospheric and bulk samples collected during Summer 2022.

A clear rhizosphere-effect is evident for almost all properties at both locations although site-specific attributes, as organic C content and pH, drive the intensity of this effect. The different latitude affects microbial activity and consequent nutrient cycling.

Finally, microbial taxonomic and functional diversity in the rhizosphere of *S. acaulis* will be discussed in relation to the different factors characterising this polar ecosystem.

**Keywords:** *Silene acaulis*, microbial diversity, C cycling, rhizosphere, arctic soils

<sup>3</sup> University of Tuscia - Department for Innovation in Biological, Agrofood and Forest Systems, Viterbo, ITALY

Iceland is a highly dynamic island where the cold climate and frequent natural events, including wind erosion and volcanic eruptions, exert significant influence on soil pedogenesis. Additionally, the scarcity of vegetated areas, stemming from historical mismanagement of the land over centuries, has intensified soil degradation affecting soil genesis. In the last decades, the Soil Conservation Service of Iceland and the Iceland Forest Service governmental agencies have aimed to improve soil ecosystem conditions through forest restoration. The research intended to investigate differences in abiotic and biotic factors by sampling soils undergone various stages of afforestation (years of forest restoration considered: 1982, 1999, and 2012). To achieve this, six trenches were excavated (two for each period of reforestation) to study morphological, physicochemical, and mineralogical soil properties and a range of enzyme activities and microbiological indicators (EL-FAME) were used to understand ecosystem functionality.

Soil morphology was extremely varied within each profile, showing one or multiple lithological discontinuities and buried horizons with exogenous material emphasized by different structures and colours. This was confirmed also by pH values (ranging from 2.84 to 7.02) and total organic carbon content (an average of mineral horizons of 15.58 g kg<sup>-1</sup> and a standard deviation of 14.4) variations. The multivariate analysis using soil chemical and biochemical properties was applied to highlight differences in the three periods of reforestation, but no evidence emerged. The Fungi/Bacteria ratio suggested a major organic matter complexity in O and A horizons of soil reforested since 1982. The other microbiological and chemical parameters mainly drove the separation of horizons with different genetic designations. Even after decades of ecological succession, the restoration of Icelandic soils faces significant challenges due to the dynamic nature of the region and its extreme climatic conditions. The process demands an extended timeframe during which the impact of the reforestation becomes noticeable, confirming the limited influence exerted by vegetation and the substantial role of abiotic components in the pedogenesis and soil's functionality.

#### EFFECT OF IN-SITU LEACHING PROCESS ON SPATIAL DISTRIBUTION CHARACTERISTICS OF SOIL PROPERTIES IN ION-TYPE RARE EARTH MINE IN SOUTHERN JIANGXI

X. ZHAO, Q. ZHANG, J. LUO

Jiangxi Agricultural University, Nanchang, CHINA

This work discusses the impact of in-situ leaching mining process on the surface soil of the ion-type rare earth mine in southern Jiangxi, and analyzes its spatial characteristics from the bottom, middle and top of the abandoned mine. The results showed that soil organic matter content and available potassium content in the abandoned mine were reduced by 36.74% and 48.29% compared with the control area, respectively. The contents of  $\text{NH}_4^+-\text{N}$  and  $\text{SO}_4^{2-}$  in the soil of abandoned mines were 55.58 times and 1.36 times higher than those in the control area. The soil pH dropped by 0.39 units compared with the control. The distribution of rare earth elements in the abandoned mine was consistent with the control, and the total amount of rare earth elements in the abandoned mine and the control area were 1.47 times and 1.77 times the background value of the total amount of rare earth elements in the soil in Jiangxi Province, respectively. The content of Zn, Pb, Cr, and Cd in the soil of the abandoned mine was significantly lower than the control, which decreased by 39.50%, 44.28%, 43.18%, and 64.84%, respectively. In terms of spatial distribution, the soil organic matter content in the middle and top of the abandoned mine was significantly lower than the bottom, but the soil ammonium nitrogen content was significantly higher than the bottom, which was 10.55 times and 7.86 times that of the bottom, respectively. The pH of the soil at the top of the abandoned mine was significantly lower than 0.11 units at the bottom and 0.17 units at the middle. Therefore, the top area of the abandoned mine is the area most seriously affected by mining, and low soil fertility, leaching agent residues, and soil acidification are the main problems faced by the abandoned mine.

#### ENABLING CITIZEN SCIENCE BY USING CELL PHONE CAMERA FOR SOIL COLOR MEASUREMENT TO ESTIMATE SOIL ORGANIC CARBON CONTENT

S. LI <sup>1</sup>, F. ZHENG <sup>1</sup>, A. KOITER <sup>2</sup>, Y. KUPRIYANOVICH <sup>1</sup>, L. COMEAU <sup>1</sup>

<sup>1</sup> Agriculture and Agri-Food Canada, Fredericton, CANADA

<sup>2</sup> Brandon University, Brandon, CANADA

Soil organic carbon (SOC) is one of the most important indicators for soil health. However, lab analysis for SOC is costly. It is well known that SOC level is reflected in the color of the soil. Experienced soil surveyors can estimate the SOC level visually. However, it takes years of training to be able to do that. The objective of this study is to establish a method to quantify SOC content by using soil color measured with cell phone images. Soil samples were taken from transects in two sites in Canada. These samples were measured for SOC in an analytical lab. A set of subsamples were prepared under different conditions (smoothed versus unsmoothed surface, 2 mm versus 63 micro m sieved, wet versus dry). Soil color was measured with a FieldSpec 4 SpectroRadiometer (reference method). The samples were then placed beside a standard color plate and pictures were taken using a cell phone. The measured color parameters with the FieldSpec and the RGB values in the photo (after adjusted based on the standard color plate) were converted to the hue, chroma and value in the Munsell soil color space. It was found that the soil color value measured with the FieldSpec and the cell phone picture methods were very well correlated. However, the cell phone method showed a negative bias in soil color values, likely due to its less ideal lighting conditions. SOC content was significantly correlated with the soil color values measured with both the FieldSpec 4 and the cell phone picture methods. Smoothed surface was better than unsmoothed surface, dry sample was better than wet sample while the differences with sieve size was small. The results suggest that it is possible to use soil color measured with cell phone image to estimate SOC. This enables citizen science for examine the spatial pattern of SOC at the field scale and the change of SOC over time.

#### MITIGATION OF ENVIRONMENTAL DAMAGE BY MONITORING CHEMICAL-BIOLOGICAL INDICES OF DISTURBED SOIL

L. SCRANO<sup>1</sup>, L. MONTINARO<sup>2</sup>, S.A. BUFO<sup>3</sup>

<sup>1</sup> BASILICATA UNIVERSITY, Srls MITIGAM SPIN- OFF BASILICATA UNIVERSITY, POTENZA, ITALY

<sup>2</sup> BASILICATA UNIVERSITY, Srls MITIGAM SPIN-OFF BASILICATA UNIVERSITY, POTENZA, ITALY

<sup>3</sup> BASILICATA UNIVERSITY, UNIVERSITY OF JOHANNESBURG, SA, POTENZA, ITALY

The Soil Biodiversity platform has invited researchers, politicians, decision-makers, industries, and states to seriously consider soil biodiversity conservation, including all kinds of microorganisms: 'The maintenance of soil biodiversity is essential to both the environment and agricultural industries.' Moreover, since 2015, the 'Cross-Sector Biodiversity Initiative (CSBI)' has presented a platform for the development and sharing of 'good practices' to be implemented concerning the protection and restoration of 'biodiversity' in extractive activities. This platform is a collaborative tool to access the knowledge and collective experience of experts in the sector. It provides practical guidance, innovative approaches, and examples to support mitigation operationalizing. In addition, CSBI has developed some guides to limit, as far as possible, the negative impacts on the biodiversity of development projects and activate the processes of mitigating the damage and recovery of biodiversity.

Our study aimed to assess the severity of soil disturbance in an industrial area using chemical-biological indicators and to suggest mitigation and restoration activities.

For soil quality restoration, it was necessary to encourage land management practices to increase the levels of organic matter and soil biodiversity. In particular, minimum soil tillage and no-tillage practices to maintain soil cover, improve its structure, maintenance, and increase of perennial plants, and finally, careful/limited use of fertilizers.

The chemical-biological indices after one year have highlighted a clear improvement in the state of health of the soil in chemical-physical, microbiological, and entomo-fauna terms. The soil and its entire community of living beings can adapt and react to difficulties.

**Keywords:** disturbed soil, industrial activity, mitigation, chemical-biological indices, fertility, biodiversity

#### MICROPLASTIC OCCURRENCE IN URBAN SOILS OF THE CITY OF CHILLÁN CHILE.

M.A. SANDOVAL ESTRADA <sup>1</sup>, W.E. ESPEJO CONTRERAS <sup>1</sup>, S. DIAZ MEDINA <sup>1</sup>, J.E. CELIS HIDALGO <sup>2</sup>, W.A. VALDIVIA CEA <sup>1</sup>, M.I. SCHOEBITZ CID <sup>1</sup>

<sup>1</sup> Department of Soils & Natural Resources, Facultad de Agronomía, Universidad de Concepción, Chillán, CHILE

<sup>2</sup> Department of Animal Science, Facultad de Ciencias Veterinarias, Universidad de Concepción, Chillán, CHILE

Plastics, formed by carbon and hydrogen atoms, have transformed modern life. Yet, their extensive production and mismanagement lead to the accumulation of microplastics (MP) in urban soils, posing concerns for human health and ecosystems. This study assesses microplastic presence in Chillán, Chile's urban soils, identifying areas with higher concentrations and potential environmental and health impacts. Conducted in January-February 2023, systematic soil samplings covered the entire urban area on a 500m grid. Sieved samples underwent microplastic extraction, identified and classified using stereomicroscope and electron microscope. Of 174 points evaluated, 166 (95.4%) contained microplastics. Among 4849 identified, 3297 (67.99%) were fibers, 1552 (32%) fragments, and 5.17% of points had over 100 microplastics. The prevalence of microplastics in 95.4% of points highlights urgent action needs to comprehend their environmental and health impacts in urban soils. Dominance of fibers (67.99%) and fragments (32%) underscores microplastic diversity in the city, originating from textiles and daily human activities. The significant fragment presence suggests larger plastic degradation in surroundings. Nine points with high microplastic concentrations (5.17%) pinpoint critical contamination areas, emphasizing precise geolocation importance. Urgency to address Chillán's urban soil microplastic pollution is evident, requiring effective waste management, public awareness, and robust environmental policies to combat this growing threat.

### 8.07 133620 - Soil Ambitions: Driving soil health into national and international policy

#### EVALUATING THE INTERVENTIONS FOR HEALTHY AND MORE RESILIENT SOILS WITHIN THE ITALIAN CAP STRATEGIC PLAN

F. VARIA, S. CRISTIANO, V. CARTA, I. CRISCUOLI, F. GALIOTO, G. DARA GUCCIONE

CREA Research Centre for Agricultural Policies and Bioeconomy, Rome, ITALY

Under the Common Agricultural Policy (CAP) 2023-2027, the impacts of the different interventions (i.e. direct payments, interventions for certain market sectors and rural development support) will be evaluated across the European Union (EU) according to the common Performance Monitoring and Evaluation Framework (PMEF).

Each CAP Strategic Plan (CSP) specifies interventions and requirements and the expected results to be assessed by using the criteria, the common indicators, and other rules established in the regulations.

Indeed, healthy and more resilient soils are essential for achieving climate neutrality, reversing biodiversity loss, providing healthy food and maintaining viable rural areas. Therefore, how to evaluate and improve the soil-related CSP interventions deserves the full attention of policy makers, evaluators, farmers, advisors, researchers, and other stakeholders.

However, according to the scientific literature and lessons learned from previous evaluations, monitoring and evaluating processes of soil-related policy interventions are still extremely challenging due to a serious knowledge gap on soil health and resilience. To date, there is no binding overarching framework at EU level that strategically defines specific policy priorities or parameters for soil protection.

This work aims to provide theoretical insights and practical suggestions for the development of those components of the monitoring and evaluation system of the Italian CSP which are significantly linked to soil-related issues. In the absence of a comprehensive methodological framework, the analysis will be based on different data sources: literature reviews, EU websites (including the EU CAP Network website with its Evaluation Knowledge Bank) and evaluation guidelines and reports at the EU and national level.

The results will open avenues for evaluation of the Italian CSP soil-based interventions by clarifying the methodological steps to be included in the evaluation designs. They will also allow the formulation of the proposed of soil-related evaluation questions which national and regional managing authorities could include in their terms of reference for independent evaluators.

### 8.08 133822 - Peatlands in a changing world

#### EXAMINING THE INFLUENCES AND TEMPORAL VARIATIONS OF SOIL GREENHOUSE GAS EMISSIONS IN AN OIL PALM PLANTATION ON TROPICAL PEATLAND

A. CHADDY <sup>1</sup>, F.E. SANGOK <sup>1</sup>, S.Y.L. LAU <sup>1</sup>, L. MELLING <sup>1</sup>, R. HATANO <sup>2</sup>

<sup>1</sup> Sarawak Tropical Peat Research Institute, Kota Samarahan, Sarawak, MALAYSIA

<sup>2</sup> Hokkaido University, Sapporo, Hokkaido, JAPAN

Currently, there is still a significant gap in data regarding the temporal variations in greenhouse gas (GHG) emissions from oil palm plantations on peatland. This gap hinders our understanding of how GHG emissions and their influencing factors vary over time in such ecosystems. To bridge this knowledge gap, a study was conducted focusing on the relationship between ground water level (GWL) and soil GHG emissions over time. The study involved measuring soil carbon dioxide (CO<sub>2</sub>), methane (CH<sub>4</sub>), and nitrous oxide (N<sub>2</sub>O) emissions in an oil palm plantation on tropical peatland, spanning across different stages of oil palm growth, from young to mature palms. These emissions were monitored monthly using a closed chamber method, from January 2010 to December 2017. Key findings include a notable decrease in soil N<sub>2</sub>O emissions as the palms aged, particularly when the soil water-filled pore space (WFPS) was between 70 to 96%, indicating complete denitrification. The study also revealed that GWL significantly affects soil WFPS and CO<sub>2</sub> emissions ( $p < 0.05$ ), especially in younger plantations. The study also found that GWL had a significant impact on soil WFPS and CO<sub>2</sub> emissions, but this was predominantly in younger plantations, suggesting that in older plantations, root activity might be a more influential factor in soil respiration than GWL. Soil CH<sub>4</sub> emissions were observed to increase with the age of the palms, with the impact of WFPS on CH<sub>4</sub> emissions being more significant than that of GWL ( $p < 0.05$ ), possibly attributed to the lower GWL at the study site. This research elucidates the dynamic relationships among GWL, WFPS, and soil GHG emissions, which vary with the age of the oil palms. The insights gained from this study are crucial for formulating effective strategies to mitigate GHG emissions from tropical peatlands, considering the dynamic nature of this ecosystem.

### 8.08 133822 - Peatlands in a changing world

#### THE APPARENT TEMPERATURE SENSITIVITY (Q<sub>10</sub>) OF PEAT SOIL RESPIRATION: A SYNTHESIS STUDY

H. LIU <sup>1</sup>, F. REZANEZHAD <sup>2</sup>, Y. ZHAO <sup>3</sup>, H. HE <sup>4</sup>, P. VAN CAPPELLEN <sup>2</sup>, B. LENNARTZ <sup>1</sup>

<sup>1</sup> University of Rostock, Rostock, GERMANY

<sup>2</sup> University of Waterloo, Waterloo, CANADA

<sup>3</sup> Ludong University, Yantai, CHINA

<sup>4</sup> McGill University, Montréal, CANADA

The temperature sensitivity (Q<sub>10</sub>) of soil respiration is a critical parameter in soil carbon dynamics modeling; yet the regulating factors and the underlying mechanisms of Q<sub>10</sub> in peat soils remain unclear. To address this gap, we conducted a comprehensive synthesis data analysis from 87 peatland sites spanning boreal, temperate, and tropical zones, and investigated the spatial distribution pattern of Q<sub>10</sub> and its correlation with climate conditions, soil properties, and hydrology. Findings revealed distinct Q<sub>10</sub> values across climate zones: boreal peatlands exhibited the highest Q<sub>10</sub>, trailed by temperate and then tropical peatlands. Latitude presented a positive correlation with The Q<sub>10</sub>, while mean annual air temperature and precipitation revealed a negative correlation. A noteworthy discovery was the pronounced negative relationship between the soil carbon-to-nitrogen ratio (C/N) and Q<sub>10</sub>, echoing the carbon-quality temperature hypothesis that decomposition is more temperature-sensitive in low-quality than in high-quality carbon. However, the relationship between C/N and Q<sub>10</sub> varied significantly between peat types. Our data analyses also revealed that Q<sub>10</sub> was influenced by soil moisture levels, with significantly lower values observed for peat soils under wet than dry conditions. Essentially, boreal and temperate peatlands seem more vulnerable to global warming-induced soil organic carbon decomposition than tropical counterparts, with wet peatlands showing higher climate resilience.

**Keywords:** Temperature sensitivity,Q<sub>10</sub>,soil respiration,peatland,soil properties

### 8.08 133822 - Peatlands in a changing world

#### CHEMICAL CHARACTERISTICS OF A TROPICAL PEAT SOIL PROFILE IN SARAWAK, MALAYSIA

F. SANGOK<sup>1</sup>, N.A. BUSMAN<sup>1,2</sup>, L. MELLING<sup>1</sup>

<sup>1</sup> Sarawak Tropical Peat Research Institute, Kota Samarahan, MALAYSIA

<sup>2</sup> Graduate School of Bioagricultural Science, Nagoya University, Nagoya, JAPAN

Tropical peatlands in Malaysia, covering about 2.5 million hectares, play a crucial role in the region's ecosystem dynamics. Approximately 26.8% of these peatlands have been transformed for agricultural use, involving land clearing, drainage, compaction, and fertilization, significantly impacting their peat soil characteristics. However, the understanding of these impacts is limited and inconsistent, influenced by varying vegetation and environmental conditions. This study focuses on the chemical properties of a tropical peat profile within the Maludam peat dome in Sarawak, Malaysia. The objective is to deepen our knowledge of the chemical processes in this coastal peat dome, which is characterized by diverse vegetation types: Mixed Peat Swamp (MPS), Alan Batu (ABt), and Alan Bunga (ABg) forests. It was observed that the MPS forest, located at the dome's edge, exhibits higher levels of humification compared to the ABt and ABg forests, where woody materials are more prevalent at greater soil depths. Using Principal Component Analysis (PCA) as an ordination method, the study reveals that the decomposition and nutrient status of the peat soil profile are key factors influencing its chemical characteristics in the Maludam peat dome. Decomposition significantly affects MPS soils, while nutrient status is more influential in both ABt and ABg soils. The variation in nutrient status among these vegetation types indicates a transition in vegetation over time, which, together with the peat water quality, contributes to the diverse chemical properties observed in the peat profile. Understanding these variations in peat soil characteristics is essential for developing effective science-based or nature-based solutions for managing and conserving tropical peatlands.

In Malaysia, approximately 26.8% of tropical peatlands have undergone conversion from peat swamp forests to agricultural land. This conversion impacts the quality and quantity of peat humification subsequently affecting the magnitude of greenhouse gas (GHG) production. Our study aimed to assess the influence of land use changes on peat soil organic matter (SOM), particularly reflected in humification degree (HD) and its correlation with the potential production of carbon dioxide (CO<sub>2</sub>) and methane (CH<sub>4</sub>). We conducted laboratory incubations under aerobic and anaerobic conditions, analyzing different forest types. Peat soil samples were collected at intervals of 0–25, 25–50, 50–75, and 75–100 cm, with HD evaluated based on the atomic ratio of C/N. Alan Batu forested site (ABt F) exhibited lower CO<sub>2</sub> production rates (7.60 and 13.11 mg kg<sup>-1</sup> d<sup>-1</sup>) compared to oil palm plantations (ABt OPP) with rates of 17.58 and 28.83 mg kg<sup>-1</sup> d<sup>-1</sup> in aerobic and anaerobic conditions, respectively. In contrast, the Alan Bunga forest (ABg F) showed higher aerobic CO<sub>2</sub> production (11.90 mg kg<sup>-1</sup> d<sup>-1</sup>) than its corresponding plantation (ABg OPP, 9.11 mg kg<sup>-1</sup> d<sup>-1</sup>). Similarly, anaerobic CO<sub>2</sub> production rates followed a distinct pattern, with ABg F at 27.38 mg kg<sup>-1</sup> d<sup>-1</sup>, significantly greater than ABg OPP at 15.43 mg kg<sup>-1</sup> d<sup>-1</sup>. Anaerobic CH<sub>4</sub> production potentials were higher in the order ABt OPP > ABg F > ABg OPP > ABt OPP. The differences in production potentials were attributed to varying HD among the forest types. ABg F, with the lowest C/N ratio and higher total nitrogen (N) content across depths, indicated greater humification. In contrast, plantation peat had lower total N content, reflecting a lower HD due to the decomposition of N-enriched SOM into humic substances. Our findings highlight the importance of considering HD variations among forest types to understand the factors influencing CO<sub>2</sub> and CH<sub>4</sub> production in tropical peatlands. This is particularly relevant when evaluating the effects of land-use changes on litter input and subsequent GHG emissions.

#### EFFECT OF LIMING ON MACRONUTRIENTS IN TROPICAL PEAT SOIL: A 5-YEAR FIELD STUDY

K.D. KANANG<sup>1</sup>, H. MOHIDIN<sup>2</sup>, A. CHADDY<sup>1</sup>, N. UJIH<sup>1</sup>, L. MELLING<sup>1</sup>

Agronomic challenges in tropical peatland are often hindered by high soil acidity and low fertility which can adversely affect the availability and uptake of essential macronutrients by plants. Liming has become a common agricultural practice to improve soil pH in peat soils. However, optimal lime rates for both productivity and cost-effectiveness remain challenging due to its substantial soil buffer capacity. Thus, a 5-year field experiment was conducted in an oil palm plantation on tropical peatland to evaluate the effects of different lime application rates on soil macronutrients. Calcium carbonate (CaCO<sub>3</sub>) was uniformly applied within a 2-meter radius of the palm circle according to the following lime rates: without lime as Control (L0), 3 t ha<sup>-1</sup> (L1), 6 t ha<sup>-1</sup> (L2) and 12 t ha<sup>-1</sup> (L3). The study measured soil nitrogen (N), phosphorus (P), potassium (K), calcium (Ca), and magnesium (Mg) in each treatment group. Results showed that liming had significantly increased soil pH from 3.5 to 4.0 ( $p < 0.001$ ). The increase in soil pH corresponded with a significant increase in both total Ca ( $p < 0.001$ ) and Mg ( $p < 0.05$ ) in soil. The application of lime significantly decreased the soil's total P and K in L1 ( $p < 0.05$ ). However, total levels of N remained unaffected ( $p > 0.05$ ). This study highlights the importance of selecting the appropriate lime rates in oil palm cultivation in peatland to improve the soil nutrient availability for plants.

#### AEROBIC METHANOTROPHY POTENTIAL IN DIFFERENT TROPICAL PEAT SWAMP FOREST TYPES IN MALUDAM NATIONAL PARK, SARAWAK, MALAYSIA

C.J. YEONG<sup>1,2</sup>, H.U. LINDANG<sup>1</sup>, A. HO<sup>3</sup>, S.Y.L. LAU<sup>1</sup>, S. LIHAN<sup>2</sup>, M.A. HORN<sup>3</sup>, L. MELLING<sup>1</sup>

Tropical peat swamp forests are important for carbon storage, but their water-saturated condition creates a favourable condition for methane (CH<sub>4</sub>) production. Methanotrophs are responsible for CH<sub>4</sub> oxidation (methanotrophy), thus are key players in the CH<sub>4</sub> cycle. Current research lacks a deep understanding of methanotrophy across various tropical peat swamp forest types. This study investigates the methanotrophy potential in three distinct forest types within a tropical peat dome in Sarawak, Malaysia. Sampling was conducted in July 2023 (dry season) in the Maludam National Park, Sarawak, Malaysia. Peat sample was collected from the topsoil (0-10 cm depth) of three different forest types namely, Mixed Peat Swamp (MPS), Alan Batu (ABt), and Alan Bunga (ABg) forests. Methanotrophy potential was assessed by incubation in 100 mL vial supplemented with 2-3% v/v CH<sub>4</sub>. Soil pH, total carbon (C) and nitrogen (N), inorganic N, and total phosphorus (P) were determined. Soil pH across different forest types was comparable, ranging from 3.90-3.95. Although total C and N were relatively similar between MPS and ABt forest, they were relatively lower ( $p < 0.05$ ) in ABg forest. Total P differed significantly ( $p < 0.01$ ) across all forest types with the highest concentration in MPS, followed by ABt, and ABg forest. Incubation results demonstrated that the methanotrophy potential differed significantly ( $p < 0.05$ ) across all forest types. The highest methanotrophy potential was observed in MPS forest ( $0.35 \pm 0.07 \mu\text{mol g dw soil}^{-1} \text{ day}^{-1}$ ), while ABg forest ( $0.05 \pm 0.02 \mu\text{mol g dw soil}^{-1} \text{ day}^{-1}$ ) showed the least methanotrophy. A strong correlation was found between methanotrophy potential and N, particularly ammonium (NH<sub>4</sub><sup>+</sup>), and a relationship with total P was observed. This study suggests a significant correlation between methanotrophy potential and soil chemical properties across different tropical peat swamp forest. Nevertheless, validation of pmoA gene abundance using quantitative polymerase chain reaction analysis will be conducted to provide a deeper insight into the regulation of CH<sub>4</sub> filter function provided by methanotrophs in different tropical peat swamp forest types.

#### ASSESSING THE IMPACT OF LONG-TERM MINERAL FERTILIZER USE ON GROUNDWATER NUTRIENTS: A COMPARATIVE STUDY IN AN OIL PALM PLANTATION AND A DRAINED SECONDARY FOREST ON TROPICAL PEATLAND

Nutrients from fertilizers, when not absorbed by trees or attached to soil particles, can dissolve and be lost through surface run-off, denitrification, and leaching processes. These substances accumulate in surface water and subsequently seep into groundwater, contributing to the deterioration of groundwater quality. Particularly in peat soils, which are highly porous, there is a significant risk of leaching losses from applied fertilizers. In oil palm agroecosystems, where high fertilizer inputs are crucial for maintaining yields, there exists a potential environmental threat particularly to clean water sources and aquatic ecosystems if excess nutrients migrate to waterways. Despite this, research into the long-term effects of fertilizer use on groundwater quality, especially in oil palm plantations located on tropical peatlands, remains limited. This study, therefore, aims to examine the long-term effects of fertilizer use on groundwater nutrients in an oil palm plantation (*Elaeis guineensis*) situated in tropical peatland, comparing it with a nearby drained secondary forest in Sibu town, Sarawak, Malaysia. Groundwater samples were collected from installed monitoring wells across 12 blocks of the oil palm plantation (OPP) (Q1-Q12) and the drained secondary forest (DSF) between January 2011 and December 2017. Sampling resumed from October 2021 to March 2022 following the planting of second-generation oil palms. The results showed that long-term fertilizer application increased groundwater pH in the OPP, particularly after the replanting of second-generation palms, compared to the DSF. Moreover, the concentrations of potassium (K<sup>+</sup>) and chloride (Cl<sup>-</sup>) in groundwater were consistently higher in the OPP than in the DSF throughout both wet and dry seasons, likely due to the leaching of these elements from soil into groundwater post-fertilization. This study is the first to evaluate and provide baseline data on the long-term impact of mineral fertilizer use on groundwater nutrients, aiming to contribute to the conservation of groundwater quality and sustainability of oil palm cultivation in tropical peatlands.

#### DEEP COLLAR INSERTION METHOD FOR SOIL RESPIRATION COMPONENT SEPARATION IN AN OIL PALM PLANTATION ON TROPICAL PEATLAND IN SARAWAK, MALAYSIA

S.Y.L. LAU, M.Y. CHIN, F. MIDOT, M.L. LO, M.S. JEE, C.J. YEONG, L. MELLING

Sarawak Tropical Peat Research Institute, Kota Samarahan, MALAYSIA

The second-largest source of carbon (C) in terrestrial ecosystems is soil respiration (Rs), accounting for nearly one-fifth of atmospheric carbon dioxide. Peatlands possess a significant proportion of the global soil carbon pool, estimated at approximately 35% or 600 PgC. Hence, the process of Rs generated from peatlands holds great significance within the context of the global carbon cycle. Studies have been conducted to quantify autotrophic (Ra) and heterotrophic (Rh) respirations separately under field conditions to gain better understanding of the below-ground C dynamics. Among the various methods used, the root exclusion technique is a popular because it is easy to use and cost-effective. A field study using the root exclusion method was conducted at an oil palm plantation on tropical peatland in Sarawak, Malaysia. The study plot consists of four different nitrogen (N) rates: without N, 31.1 kg N ha<sup>-1</sup> yr<sup>-1</sup>, 62.2 kg N ha<sup>-1</sup> yr<sup>-1</sup>, and 124.3 kg N ha<sup>-1</sup> yr<sup>-1</sup>. Investigations were conducted on soil CO<sub>2</sub> emissions, soil CO<sub>2</sub> profiles, and physicochemical properties by soil depth. Soil CO<sub>2</sub> emissions from Rh chambers were found to be greater (mean 3047.4 mg CO<sub>2</sub>-C m<sup>-2</sup> h<sup>-1</sup>) than those from Rs chamber soils (mean 1782.4 mg CO<sub>2</sub>-C m<sup>-2</sup> h<sup>-1</sup>). On the other hand, the average soil CO<sub>2</sub> concentrations by depth in the Rs and Rh chambers were 43198.11 ppm and 20553.36 ppm, respectively, greater than in the Rs chamber. The bulk density of Rh chamber soils was significantly larger than that of Rs chamber soils, with mean values of 0.4 g cm<sup>-1</sup> and 0.26 g cm<sup>-1</sup>, respectively. Certain soil layers in Rh chamber soils had slightly higher moisture contents than in Rs chamber soil; this might raise Rh. In this study, nitrogen fertilization had no significant effect on CO<sub>2</sub> emissions in the Rh or Rs chamber soils. Separating Rs into its autotrophic and heterotrophic components in the field is typically challenging because of the multiple biological and ecological processes that govern them.
